HUELGOAT, Le, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Chateaulin; nine miles N.W. of Carhaix. The place contains 765, and the canton 9496 inhabitants, on a territory of 305 kilometres, in seven communes.

HUELMA, a town of Spain, in Grenada; 13 miles S.W. of Grenada.

HUERNA, in Botany, so called by Mr. R. Brown, "in memory of Julius Hueranus, one of the earliest collectors of Cape plants, and from whose drawings the first account of Stapelia was taken," from which genus the present is separated.—Brown. Afclep. 11. — Clals and order, Pentandria Diggia. Nat. Ord. Contorte, Linn. Apocirene, Jull.

Eff. Ch. Corolla bell-shaped, its limb in ten segments, the intermediate ones very small and tooth-like. Column of fructification concealed. Crown of the flaments double; the outer in five cleft segments; inner five undividedawl-shaped leaves, gibbous at their base, alternate with the segments of the outer. Anthers simple at their summit; maffes of pollen erect, attached by their base, cartilaginous and pellucid at one edge. Stigma pointlet.f Pollicies nearly cylindrical, smooth. Seeds cocoons.

The plants which compose this genus have the remarkable fleshy, angular, and toothed habit of Stapelia, and the whole form of the third section of that genus in Wildd. Sp. Pl. v. 1. 1202; (with a ten-toothed corolla,) is thought to belong to Huernia. Mr. Brown has however examined only the comuneulata, Macon. Stapel. t. 6; vanoula, t. 3.; and guttato, t. 4. They are all natives of the south of Africa. The flowers of these three are all pale yellow, richly dotted with red or dark purple. The reticulata, t. 2, which has every appearance of being of the same genus, bears a splendid crimson corolla, reticulated with yellow lines.—As far as habit is concerned, we cannot but think this genus artificial, the crown of the flaments in Stapelia, and its nearest allies, being somewhat liable to aberration of character.

HUERS. See BALKERS and Pichard FISHERY.

HUERS, the name given to certain fountains in Iceland, which form jets d'eau of scalding water 94 feet high and 30 feet in diameter. They arise from cylindrical tubes of unknown depth; near the surface they expand into apertures of a funnel-shape, and the mouths spread into a large extent of flashtitical matter, formed of succedee fealty concentric undulations. The occurrence of this phenomenon is foretold by noises roaring like the cataract of Niagara. These hues are not confined to the land; they also rise in the sea, and form scalding fountains amidst the waves.

HUESCA, a town of Spain, in the province of Aragon,
HUET, Peter Daniel, in Biography, a learned French prelate, was born at Caen in 1630. Owing to the death of his parents, his education devolved upon an aunt who placed him, while young, in the Jesuits' college at Caen, where he was distinguished by industry and an amiable disposition. He cultivated with much success not only polite literature, but mathematics, philosophy, jurisprudence, and the Hebrew language. In connection with the latter study, he cultivated the acquaintance of the learned Bochart, the Calvinist minister of Caen, but to avoid suspicion, their conferences were first held in secret. When he attained to the age of manhood he visited Paris, and began to indugle his passion for books, by purchasing as many as his purse would admit of. In 1652 he accompanied Bochart in a journey to Sweden, whither that learned man had been invited by queen Christina. He was tired of the country before the approach of winter; and leaving Bochart there, he returned through Holland, where he passed some time in visiting the universities and men of learning. On his arrival at Paris, a controversy arose between him and Bochart, concerning Origen's commentary on St. Matthew's gospel, which put an end to their friendship. In 1661, Huet published his first work, entitled "De Interpretatione," the object of which was to confine, within due limits, the licence of translators, especially those of the scriptures. He instigated, about this period, an academy of physics at Caen, the members of which assembled weekly at his house, where they read memoirs, and conducted experimental enquiries. This institution was patronized by the minister Colbert, through whose influence the royal munificence was extended, not only to the society, but also to its founder, and Huet was put on the list of learned men upon whom pensions were regularly conferred. In 1670, when Bofillet was appointed preceptor to the dauphin, Huet was called to the office of sub-preceptor. In this post, one of his employments was to superintend that edition of the classics which is commonly known here as the Delphin edition. In 1674 he was elected a member of the French academy, in 1676 priests' orders, which he hitherto deferred taking, were given him, and in 1678 he was presented to the abbey of Annay in Normandy, a place, the beauties of which he has celebrated in verse, and which became his favourite residence. He was presented, in 1685, to the bishopric of Soissons, but owing to the disputes then existing between France and Rome, he never obtained his bulls, nor took possession of his see, and which he readily exchanged in 1690 for that of Arranches, which was his native province. To this see he was not consecrated till 1692, and in 1699 finding the burthen of the situation too great for his comfort, he begged permission to resign his bishopric, and was presented by the king, as a pecuniary compensation, with the abbacy of Fontenay near Caen. Here he became the victim of several law suits, and at length made his retreat from the world and its vexations into the house of the Jesuits at Paris, to which he bequeathed his library. Here he remained absorbed in his studies, and in intercourse with a few learned men, till his death in January 1721, at the great age of ninety-one. Huet was the author of many learned works, and may be regarded as one of the most distinguished literary scholars of the age in which he flourished. Of his various publications the following have been translated into English, "On the Origin of Romances," "On the Situation of the Terrestrial Paradise," "History of the Commerce and Navigation of the Ancients," and "On the Weakness of the Human Understanding," Moreri. HUETA, in Geography. See GUETA. HUF, a town of European Turkey, in Moldavia, on the Pruth; 50 miles S.S.E. of Jaffi. N. lat. 46° 14'. E. long. 46° 19'. HUG, or Cornu Huc, a term used in wrestling, when one has an adversary on his breast, and holds him fast there. HUGH, in Biography, abbot of Flavigny, who flourished in the beginning of the twelfth century, celebrated for his talents as an ecclesiastical historian, defended from an illiblurious family, was born in the year 1065. He embraced the monastic life in the abbey of St. Vannes at Verdun, but with the members of that community were differing, he, together with the other monks, took refuge at the monastery of Flavigny, in the diocese of Autun. Here he acquired so much esteem and respect, that, upon the death of the abbot, in 1097, he was elected to that dignity, though he was not more than thirty-two years of age. He was author of "Chronicon Verdunense," which is divided into two parts, the first contains an ecclesiastical history from the birth of Chrilt to the close of the tenth century, and the second a continuation of the fame from 1062 to 1102. This second part furnishes us with much valuable information concerning the ecclesiastical affairs of France in the eleventh century. It was drawn out of obscurity by father Labbe, who calls it an invaluable treasure, and printed it in the first volume of his "Bibliotheca nova Manuscriptorum," from a supposéd autograph of the author, found in the Jesuits' college at Paris, Moreri. Hugh of Fleury, a learned French monk, who flourished about the year 1120, and embraced the ecclesiastical life in the abbey of Fleury. He was author of " Chronicon Libris VI. ad Ivonem Carnotensem," commencing with the reign of Ninnus, king of the Alyssinians, and terminating with the death of the emperor Lewis the Pious, in the year 840; and also of a short, but well digested chronicle, from the beginning of the world to the reign of Lewis the Pious. Hugh was author likewise of "Lib. II. de regia Potestate, et facerodotali Dinignet, ad Henricum Angilis Regem," which is thought by some critics to be the most valuable of his works. Moreri. Hugh of St. Victor, was born near Ypres, in Flanders, about the year 1097. When he was eighteen years of age, he entered into the congregation of the canons regular of St. Augustine, at the monastery of St. Victor, in Paris, where he spent the remainder of his life, and rose to the office of prior. In 1150 he was appointed to the theological chair, which he filled with so much reputation, that he was commonly called a "second Augustine." He died in 1159, when only in the 44th year of his age. His works were collected and published in three volumes folio. They have been several times reprinted. HUON of St. Churis, or St. Theodoric, a French monk, and cardinal in the thirteenth century, was born in the vicinity of Vienne, in Dauphine. In 1225 he entered into the Dominical order of preaching friars, of which he was soon appointed provincial. He was afterwards created doctor by the faculty of the Sorbonne, and was sent by pope Gregory
HUGHES, John, in Biography, an English poet, was born, in 1677, at Marlborough. He was educated in London, was a student in the academy of Mr. Thomas Rowe, and was a contemporary of Dr. Watts, Mr. Say, and some others who arrived at eminence. Mr. Hughes attached himself to polite literature, and was a practitioner in the fine arts. He obtained a place in the office of ordnance, and was secretary to various commisions, for purchasing lands for the use of the Royal docks. His employments under government, and his political principles, induced him to exercise his poetic talents upon public topics. He published "A Poem on the Treaty of Ryswick:" "The Court of Neptune:" "A Poem on the Return of King William from Holland:" and a pindaric ode, entitled "Of the Heave of Naffau." His sentiments and poetry rendered him acceptable to the Whig party, and connected him with Addison, Steele, and other persons of distinction. He became one of the writers in the Tatler, Spectator, and Guardian. His taste for music introduced him to the acquaintance of several eminent composers, and led him to write many pieces for musical accompaniment. In 1715 he published, by subscription, an edition of Theocritus, by which he gained great credit as an elegant critic. In 1717 he obtained the patronage of lord chancellor Cowper, who gave him the place of secretary to the commisions of the peace. His want of health interrupted the enjoyment of his good fortune. Under much bodily languor he compos'd his tragedy of "The Siege of Damascus," which was brought on the stage in February 1717, 1719-20, on which night the author finish'd his earthly career, at the age of forty-three. He was a man generally beloved and respected: his temper was amiable, his morals were pure, and his integrity was unimpeachable. His tragedy is the principal piece of his composition. In 1735 a complete collection of his poems and dramatic pieces was published with an account of his life in two volumes, 12mo. by his brother-in-law, William Duncombe, esq. The younger brother, Jasper Hughes, published a translation from Claudian of the Rape of Proserpine; and the story of Sextus and Emilio from Lucan; also Suetonius’s Lives of the Caesars, and some of Cervantes novels. Another John Hughes, fellow of St. John’s college, Cambridge, published, in 1712, an edition of Chryfodrom on the Priesthood.

Mr. John Hughes, during the early part of the last century, was our principal lyric poet; and not only wrote for muse, but was himself a performer in Brittan, the small-coal man’s concerts. He wrote the English opera of "Calypso and Telemachus," for Galliard to set, and "Apollo and Daphne," for Dr. Pepusch, with cantatas for both. His verses on Mrs. Barber’s elopement, and on the rivalry of Margarita and Mrs. Tofts, shews that he interlaced himself in the transations of the musical world, and was on the watch to ridicule the folies and dislay the talents of its profilers.

HUGHESBURG, in Geography, a town of America, in Northumberland county, Pennsylvania, called also "Ca-

HUGOTOWN, a town of St. Mary’s, one of the Scilly islands.

HUGO, Charles Louis, in Biography, a French writer, abbot of Etival, and bishop of Pellemais, died in 1715. His chief works are, "Annales Premonstratensium," which is a curious history of the monastic order. "Vie de St. Norbert, Fondateur des Premonstres:" "Sacra Antiquitates monumenta historica, dogmatics, diplomatia," 2 vols. fol. "Traité Historique et Critique de la Maifon de Lorraine." This last, on account of the freedom with which crowned heads are treated in it, was published under the borrowed name of Balecourt, and pretendedly printed at Berlin.

Gen. Ch. Col. Perianth inferior, of five ovate, acute, concave, coriaceous, permanent leaves; the two outer ones large. Cor. Petals five, roundish, large, spreading, emarginate, contracted at the base into a thin claw, attached to the cup formed by the filaments. Stem. Filaments ten, awl-shaped, equal, shorter than the corolla, united by their base into a little cup; anthers roundish, furrowed, incumbent. Pfl. Germanus superior, roundish; styles five, thread-shaped, longer than the filaments; flagesma capitate, orbicular, flat. Peric. Drupa globoso, of one cell. Sed. Nut globoso, deeply fribatet, of ten cells; kernels oblong, compressed, curved at the back.

Obs. "The two outer leaves of the calyx are entirely downy on their outisde. The middle one is likewise downy, except a part of it covered by one of the former, where it is smooth and shining, like the two innermost, which are downy at their points only. Five of the filaments are a little shorter than the rest. Five of the kernels seem often to be abortive; hence perhaps it happened that Cavanilles took the nut to have but five cells. In that which I opened there were more than five kernels." Schreder.

Eff. Ch. Calyx simple, of five permanent leaves; two of them external. Petals five, Styles five. Drupa with a furrowed nut of about ten cells.

1. H. Myntex. Linn. Sp. Pl. 944. Lamarck. Dict. v. 3. 149. Wild. n. 1. (Modera-cani; Rhede. Malab. v. 2. 29. t. 19.)—Spines opposite, revolute. Leaves obvate, smooth, entire.—Native of the East Indies, in sandy ground. A flendor furab, about 12 feet high, with numerous, short, leafy, not quite opposite branches, each of which bears, about its middle, a pair of remarkable frong, revolute, smooth finies. The resemblance of these to a pair of mufich, is said to be express'd in the Indian name Modern, as in the Latin one Myntex. Leaves numerous, fatteret, from one to two inches long, obvate, entire, rather pointed, finely veiny, smooth on both sides. Footstalks short, broad and downy. Stipula awl-shaped, downy. Flowers numerous, on axillary, simple, silky stalks, about the ends of the branches. Petals yellow, frigatet. Fruit shining, near half an inch in diameter.—The wood is said to be of a reddish brown, with a grateful aromatic ouder. The root is effemed
useful as a topical application to inflamed or swelled parts, and even in the bite of the hooded serpent, Caluber Novia. It is also given internally for febrile disorders in children, for the colic, worms, &c. The fruit has a red tasteless pulp.

2. H. ferrata. Lamark. Dict. v. 3. 140. Willd. n. 2. (H. Mysilax; Cavan. Diff. 175. t. 73. f. 1.)—Spines opposite, revolute. Leaves elliptic-lanceolate, serrated, smooth, with glandular hairs at the origin of the veins.—Gathered by Commeron in the isle of Mauritius. Cavanilles mistook it for the former, from which it is very distinct. The leaves are larger, more acute, and strongly serrated, furnished at the origin of their veins with tufts of hair as in the Laufrinius. The young leaves only are very silky. Flower-buds somewhat coriaceous. This is the species known in Lamark's t. 572, after Cavanilles.

3. H. tamenofa. Cavan. Diff. 178. t. 73. f. 2. Willd. n. 3. Lamark. Dict. v. 3. 150.—Leaves elliptic-oblong, serrated, downy on both sides. Stipulas ovate.—Gathered by Commeron in the isle of Mauritius, with the leaf, from which it seems sufficiently distinct in having broader, rather obovate, downy leaves.

HUGUENOTS, an appellation given by way of contempt to the reformed or protestant Calvinists of France. The name had its first rise in 1560; but authors are not agreed as to the origin and occasion of it: but one of the following seems to be the least forced derivation.

One of the gates of the city of Tours is called the gate Fourgon, by corruption from feu Hugon, i.e. the late Hugon. This Hugon was once count of Tours, according to Eginhardus, in his life of Charles the Great, and to some other historians. He was it seems a very wicked man, who by his fierce and cruel temper made himself dreadful; so that after his death he was baptized to walk about in the night time, beating all those he met with: this tradition the judicious Thuanus has not scrupled to mention in his history.

Davila and other historians pretend that the nickname of Huguenots was first given to the French protestants, because they used to meet in the night time in subterraneous vaults near this gate of Hugon; and what seems to concur with this opinion is, that they were first called by the name of Huguenots at this city of Tours.

Others assign a more illustrious origin to that name; and say that the leaguers gave it to the reformed, because they were for keeping the crown upon the head of the royal line defended from Hugh Capet; whereas they were for giving it to the house of Guife, as defended from Charles the Great.

Others again derive it from a French and faulty pronunciation of the German word eigennofen, signifying confederates, and originally applied to that valiant part of the city of Geneva, which entered into an alliance with the Swiss cantons, in order to maintain their liberties against the tyrannical attempts of Charles III. duke of Savoy.

These confederates were called Eigennof, whence Huguenots. The persecution which they underwent has scarce its parallel in the history of religion; though they obtained a peace from Henry III. in 1570, it was only of short continuance. This peace was the source of that civil war, in which the ambitious and powerful house of Guife, intiated by the fangraly suggestions of the Roman pontiffs, aimed at nothing less than the extirpation of the royal family, and the utter ruin of the Protestant religion; while the Huguenots, on the other hand, headed by leaders of the most heroic valour and the most illustrious rank, combated for the religion and for their sovereigns with various success. These dreadful commotions, in which both the contending parties committed such deeds as cannot be remembered without horror, were, at length, calmed by the fortitude and prudence of Henry IV. This monarch, indeed, sacrificed the dictates of conscience to the suggestions of policy; and imagining, that his government could have no stable or lasting foundation, as long as he persisted in dishorning the authority and jurisdiction of Rome, he renounced the reformed religion, and made a solemn and public profession of popery. Perceiving, however, on the other hand, that it was not possible either to extirpate or suppress entirely the Protestant religion, he granted to its professors, by the famous edict of Nantes, (which se,) in the year 1598, the liberty of serving God according to their consciences, and a full security for the enjoyment of their civil rights and privileges, without persecution or molestation from any quarter whatever. The sufferings of the Huguenots were afterwards renewed, when every method which artifice or perfidy could invent had been practised in vain against the Protestants under the reign of Lewis XIV. The bishops and Jesuits, whose counsels influenced the cabinet of this prince, judged it necessary to extirpate, by fire and sword, this revolting people; and thus to ruin, as it were, by one mortal blow, the cause of the reformation in France. Their insidious arguments and important solicitations had such an effect upon the weak and credulous mind of Lewis, that, in the year 1685, trampling upon the most solemn obligations, and regardless of all laws, human and divine, he revoked the edict of Nantes, and thus deprived the Protestants of the liberty of serving God according to their consciences. This revocation was accompanied, indeed, with the applause of Rome; but it excited the indignation even of many Roman Catholics, whose bigotry had not effaced or suspended, on this occasion, their natural sentiments of generosity and justice. It was moreover followed by a measure still more tyrannical and shocking: even an express order, addressed to all the reformed churches, to embrace the Romish faith. The consequences of this cruel and unrighteous proceeding were highly detrimental to the true interests and the real prosperity of the French nation, by the prodigious emigrations it occasioned among the Protestants, who sought, in various parts of Europe, that religious liberty, and that humane treatment, which their mother country had so cruelly refused them. Those among them, whom the vigilance of their enemies guarded so closely as to prevent their flight, were exposed to the brutal rage of an unrelenting fดldonian, and were assailed by every barbarous form of persecution that could be adopted to subdue their courage, exhaust their patience, and thus engage them to a feigned and external profession of popery, which in their consciences they beheld with the utmost aversion and disgust.

In other countries, and particularly in our own, they found an asylum, and communicated in return for the protection they experienced the benefit of their skill and industry. Moine's EccI. Hist. vol. v.

HUIDE, in Geography, a town in Norway, in the diocese of Christianand; 20 miles E. of Skene.

HUIDINGS, a small island in the North sea, near the west coast of Norway. N. lat. 59° 5'. E. long. 5° 42'.

HULGRUND, and Hulgrundet, two small islands on the west side of the gulf of Botnia; the first in N. lat. 60° 47'; E. long. 17° 11'; the second in N. lat. 62° 36'; E. long. 17° 27'.

HUIS, L., a town of France, in the department of the Ain, and chief place of a canton, in the district of Bellay; 6 miles W. of Bellay. The place contains 1123, and the canton 6465 inhabitants, on a territory of 175 square miles, in 13 communes.

6 HUISSEN,
HUISION, a walled town of Germany, in the duchy of Cleves; 10 miles N.N.W. of Cleves.

HUISIER, a French name for an usher, serjeant, or beadle.

HUITAN, in Geography, a town of Sweden, in West Bothnia; 25 miles N. of Lulea.

HUITINGO POLLACHUS, in Ichtyology. See GADUS Pollachii.

HVITTISBURG, in Geography, a town of Sweden, in the government of Abo; 11 miles N. of Bierneborg.

HUIUS, or HUIUSE DURS, in Mythology, a famine given by the Romans to Fortune. She had a temple at Rome, erected by C. Catullus.

HULDIBARRY, in Geography, a town of Bengal; 48 miles N.E. of Purneash.

HULDOOKRA, a town of Bengal; 46 miles S. of Sudder.

HULDOOA, a town of Hindooslan, in the circur of Dooab; 50 miles N.W. of Patiarry.

HULDSCHIN, or HOLTSCHEIN, a town of Silefia, in the principality of Oppau; 11 miles E. of Troppau. N. lat. 49° 48'; E. long. 18° 12'.

HULET PAXIAS, a lake of Paleftine, anciently called lake "Merom," into which runs a river of the fame name, anciently denominated the "Dan."

HULIN ROCKS, otherwise called the Maid's rocks, in the North channel of the Irish seas, always above water, which lies about 6 miles N.E. from Louth Larno, on the coast of Antrim. N. lat. 54° 57'; W. long. 5° 37'.

HULKS are large vessels, having their gun-decks from a hundred and thirteen to a hundred and fifty feet long, and from thirty-one to forty feet broad, and fitted with an apparatus, in order to fix or take out the masts of his majesty's ships, as occasion requires. They will carry from four hundred to a thousand tons.

Anciently, the word bulka seems to have signified a small vessel.

Hulk is also a name bestowed on any old vessel laid by, as unfit for farther service. It is probably derived from the oxinax, or vessels of burden of the ancient Greeks.

HULL, or KINGSTON-UPON-HULL, in Geography, a borough, market-town, and sea-port in the East Riding of the county of York, England, is situated on the western side of the river Hull, and the northern bank of the river Humber, at the distance of about 25 miles from the mouth of the latter; nine miles S. of Beverley; 173 N. of London; and 38 S.E. of York. It extends nearly two miles in length, and in a direct line, in which extent it includes the adjoining parishes of Sculcoates; and to rather more than half that distance in a parallel direction towards Beverley. The town originated in the year 1296, under the immediate patronage of king Edward I., who, on his triumphant return from Scotland, projected the foundation of a port, &c. at this place, then a small hamlet, called Wyke, and put his design immediately into execution. Peculiar privileges were granted to builders and refidants, together with a royal charter, velling the government in a warden and the body of freemen; and the new-formed town was distinguished by the appellation of Kingston, or Kingstown-upon-Hull. Edward founded a house of White friars, and caused a hall to be built for his own residence. This was probably given to the De la Poles, for soon afterwards a magnificent manor-house was erected by that wealthy family, which was frequently honoured with the royal presence, and falling to the crown by the attainer of Edmund de la Pole, earl of Suffolk, in 1508, became for some time the residence of king Henry VIII.

So rapid was the progress of the place, that, in about fifty years from its foundation, it was called upon to furnish king Edward III. with 16 ships and 460 men. In Leland's time it was a fair and well built town; and, according to Camden, it possessed stately edifices, strong fortresses, ships well equipped, a number of merchants, and abundance of all kinds of wealth; having been favoured with not less than fifteen charters from various succedive monarchs. It was first fortified under a charter from king Edward II., and the walls repaired and strengthened with towers of brick in the time of king Richard II. by Sir Michael de la Pole, who appears to have revived in this place the art of brick-making, which had fallen into disuse since the time of the Romans. King Henry VIII. built two block-houses and a citadel on the east bank of the river Hull, at an expense of 23,500l., although he drew great part of the materials from the dissolved houses of Black and White friars, and the church of St. Mary. King Charles II., in 1681, laid out a vast sum in improving the fortifications, which had suffered considerably from the severe siege of the town by the earl of Newcastle, and during the civil wars in the preceding reign. Within the last 35 years, the whole of these ancient works of defence, with the gates of the town, have been demolished, except two of the fortresses built by Henry, which, being guarded by several batteries and modern erections, are now converted into magazines, capable of containing more than 25,000 stand of arms, and ordnance stores for twelve or fifteen full of the line, defend by a regular garrison.

Hull consists of three principal divisions, formed by the intervention of the docks, which, occupying the greater part of the space where the walls formerly stood, nearly infuse the old town. That on the north side of the old dock is in the parish of Sculcoates; all its buildings have been erected within the last thirty years, and form several spacious and handsome streets. A neat hall has been built for the administration of justice, &c. this part of the town being in the county of York, and not under the jurisdiction of the magistrates of Hull. The other division has arisen full more recently, and lies to the west of the Humber dock, occupying the situation of the ancient hamlets of Wyke and Myton; by which latter name it is now distinguished, and is included in the county of the town of Hull. A suburb also has lately sprung up, on the Holderness side of the river, in the parishes of Drypool and Sutton, encompassing the garrison, and connected with the town by a bridge of four ilone arches, rebuilt in 1787, with a draw-bridge in the centre, which has this year (1811) been renewed on a very ingenious and novel construction, and is wide enough to admit the largest vessels that have occasion to pass through it. The whole town stands on a level tract of ground, within a short distance of the Yorkshire wolds; the principal streets are broad and well paved, and in lighting and watching it is not inferior to any place in the kingdom. A few years ago, it was computed that about 200 houses were built annually, but since the interruption to the Baltic trade, the principal source of revenue to this port, that number has been much diminished.

The edifices for religious worship belonging to the establishment are two parish churches, that of the Holy Trinity and St. Mary's; with a chapel of ease, and the chapel of the Trinity-house and Charter-house. The church of the Holy Trinity, a noble structure, was first erected in the reign of king Edward II.; the tower and west end were added about the time of king Henry VII., by whose successor, Hull
HULL.

was the site of a suffragan bishop, who possessed a
flety palace in the High-street, long since destroyed. The
church, however, remained under that of the neighbouring
village of Hesle, until separated by an act of parliament in
1661. St. Mary’s was formerly a much larger structure,
and belonged to the priory of Ferryhill. Great part of it,
including the Reecipe, was pulled down by king Henry VIII.
as obstructing the view from his palace. St. John’s is a
chapel of ease to the Holy Trinity, and was founded in
1792 at the sole expense of the Rev. Thomas Dikes, LL.B.
the present incumbent. There are also various meeting-
houses for the peculiar doctrines and worship of all the pre-
vailing sects.

The charitable institutions in Hull are numerous. The
most ancient and splendid is that of the Trinity-house, found-
ed by subscription in 1369, and rebuilt in 1753; its funds
have been progressively augmented by legacies and benefac-
tions. It was incorporated by letters patent in the reign of
Henry VI; and itscharter and grants have, at various
subsequent periods, been renewed and extended. The fund is
considerably increased by a monthly contribution of sixpence
from every seaman failing from this port; when supernumerated,
or disabled, they obtain relief, as do also their widows and
children, from this charity. Several distinguished characters
have been admitted to the freedom of this corporation
which is governed by wardens, brethren, and assistants. In
a marine-school, connected with it, thirty-six boys are, for
three years, clothed and educated for the sea service; the
guild also provides North sea pilots for the royal navy, when
required by government. The Charter-house hospital is
worthy of particular notice; it was founded, together with
an adjoining priory, by Michael de la Pole, for the support of
a certain number of penitents, denominated brothers and
fathers; under the superintendence of a master, who enjoys a
salary of 100l. per ann., with a house and garden. Sev-
eral other smaller hospitals, for similar purposes, are distin-
guished by the names of the respective founders, viz.
Litter’s, Gregg’s, Crowle’s, Watfion’s, (bishop of St. Da-
vid’s), Gee’s, Harripon’s, Ratcliff’s, and Weaver hospitals.
The workhouse is a large building, commonly known by the
name of Charity hall. For the relief of the indigent sick
and maimed, a general infirmary was erected, in 1782, by
voluntary contributions, on a plan superior to most establish-
ments of the kind, which has been the means of restoring
to health near 9000 persons. Here are likewise a free gram-
mar-school, founded by Alcock, bishop of Ely, in 1486,
which enjoyed considerable reputation, especially under its
late master the Rev. Jof. Milner, A.M.; the Vicar’s-school,
established by the Rev. W. Mason, father of the poet of
that name; a school for girls, and a valuable institution for
putting out poor boys apprentices, endowed by Ald. Cog-
gan, and another for orphans, endowed by Ald. Ferris.
Two handsome buildings have also been recently erected, ca-
cable of containing 500 boys, and 250 girls, who are in-
structed with great success, according to the improved fystem
of education. The chief part of the expense, as also that
of several Sunday-schools and other charities, is defrayed by
voluntary subscriptions.

Beside the various buildings already noticed, there are the
custom-houses, intended originally as an exchange also, but
having been long diffused for that purpose, the present com-
fortable room, with a news-room over it, was designed and
executed in 1794, by and at the expense of an individual,
though with a view to his ultimate advantage; the assembly
rooms, not now adequate to the wants and opulence of the
town; the god; the Neptune hotel; the Rodney and

Minerva lodges of Free-masons, the former of which is a
most elegant and handsome room; the subscription library,
built in 1775, and enlarged in 1806, a great advantage to the
inhabitants, and containing many thousand volumes; and the
theatre royal, rebuilt in 1829, a spacious and convenient
structure, the interior of which is fitted up in a superior
style of comfort and elegance. The avenue from the mar-
et-place to the Humber was lately widened, by taking down
the guild hall, a mean brick building, and on its site foun-
ders were erected, which, for convenience, elegance, and ven-
tilation, may challenge comparison with any in the kingdom.
The old stables being likewise removed, the beautiful east
cap of Trinity church is again thrown open to the market-
place, in the centre of which stands an equesfrian statue of
king William III. erected in 1734. Until a new guild hall
shall be provided, the corporation transact business in a large
house fitted up for the purpose. Among the public accom-
modations enjoyed by the inhabitants, may be reckoned the
Barton-boats, which crosses the Humber every tide, to and
from Barton, a distance of about seven miles.

The commerce of Hull will be best appreciated by a state-
ment of the annual exports and imports for a few years.
The tonnage of this port was, several years ago, inferior
only to that of London, Liverpool, and Bristol; its cus-
toms only to those of the former two. It sends at present
nearly thrice as many ships to the whole fisheries as London,
and, exclusive of the latter port, more than all Great Brit-
ain besides. Its facilities of communication with the interior, by
means of the Ouse and Trent, and the canals communicating
with them are very great. The gross amount of the customs
was

The number of ships (British and foreign) that entered
inwards, and cleared outwards, from and to foreign parts,
also of coaling-veffels, was,

The dock was undertaken, according to act of parliament,
in 1774, and completed within four years; the entrance is im-
mediately from the river Hull; it extends in length about
600 yards; in width 85; and is 23 feet deep, is capable of
containing 100 sail of square rigged vessels; and, with the
wharfs and quay, occupies a space of more than thirteen
acres; containing in the dock 48,188 square yards, in the
quay 17,179; exceeding in capacity the largest in Liverpool,
and now only surpassed by those of London; when made it
was the largest in the kingdom. The subscribers to the
dock are incorporated by the title of "The Dock Company
at Kingston-upon-Hull." The original number of shares
was
HUL

was 120, but the trade of the port requiring further accommodation, two other acts of parliament were obtained in 1802 and 1805, by which the company was empowered to increase them to 180, the money arising from which, amounting to £25,997, was appropriated to the making of a new dock, which was completed under the title of the Humber dock, in 1809, at an expense of £220,000. It opens into the Humber by a lock of excellent workmanship, large enough to admit a fifty-gun ship, crossed by an iron bridge in two parts, of very ingenious mechanism. The area of the dock and quays is ten acres, with a bain of four acres; its length 350 yards, width 114, and depth 29 feet; and it is intended to communicate with the old dock at some future time, which, when effected, will wholly infallate the old town. The company is entitled to certain duties on all ships entering the port; the profit divided on the shares was,

The manufactures of Hull are various and extensive; one of the principal branches is that of expressing and refining oil from linseed, and preparing the residue for feeding cattle; the process is chiefly effected by mills worked by the wind. The largest and finest mills in the kingdom of this kind, both for the above purpose and for grinding corn, are to be found in great numbers near this town; their machinery is excellent, and many of them are from 80 to upwards of 150 feet in height. An iron-foundery, two largeugar-houses, an extensive ropework, and several white lead manufactories, Greenland yards, numerous dry-docks, shipbuilders' yards, and rope-walks, where a great number of hands are constantly employed; and several large breweries are amongst the most important, but do not comprise half the manufactories now existing in the town.

The council civil authority over the town, and the several places within what is termed the county of the town of Kingston-upon-Hull, a district of more than eighteen miles in circumference, well of it, is, by various royal charters, particularly those of Henry VI. and King Charles II., vested in the corporation, which may confine the mayor, the recorder, twelve aldermen, the sheriff, two chamberlains, a town clerk, a water-bailiff, and other officers, besides a high sheriff, who is generally some nobleman of rank. The mayor is the Humber and possebly of power of life and death over criminals within his jurisdiction. The judges of assize visited this town, but of late years this has been discontinued, and all trials are removed to York, though causing a great additional expense to those concerned.

Hull returns two representatives to parliament: the right of election of whom, as well as of the several principal members of the corporate body, except the recorder and high sheriff, is vested solely in the burgesses or freemen of the town, an important body, amounting to upwards of 2,000. The population returns to parliament in 1861, specified, that the town and county contained 47,573 houses, occupied by 295,816 persons, of whom 13,051 were males, and 16,465 females; this does not include the adjoining populous parish of Sculcoates, nor the suburb on the east of the river Hull. A fair is held annually in October, and the markets are abundantly supplied, especially when the tide suits for the Lincolnshire farmers to cross the Humber, on Tuesdays, Fridays, and Saturdays.

Hull has, at different times, given birth to men distinguished on various accounts. In the first rank must be placed her representative in parliament, that incorruptible patriot, Andrew Marvell, whose father was lecturer of Trinity church; and, in later times, a most worthy man and excellent poet, the Rev. W. Mason, A.M. son of the late vicar of the same. It likewise gave the titles of earl and duke, both now extinct, to the family of Pierrepont.

The village of Sculcoates, though not in the county, may justly be considered as forming a part of the town of Hull: a portion of the old dock is included within it. The church, situated towards the northern extremity of the parish, is a neat uniform structure, rebuilt in the year 1763, and contains some fragments brought from the neighbouring abbey of Minster.

Hull River, in the East Riding of Yorkshire, is a small river, which falls into the Humber at the town of Kingston-upon-Hull, better known by the name of Hull only, and as being the fourth sea-port in point of importance in the British dominions. The Hull is made navigable from the Humber, about twelve miles, to Aike-back mouth, the entrance of the Driffield navigation. See CANAL.

Hull and Leven Canal, an inland navigation in Yorkshire, East Riding, made in pursuance of acts of parliament obtained in 1801 and 1805; it extends about three miles from the Hull river up to the town of Leven. See CANAL.

Hull, the Indian Nantucket, a town of America, in Suffolk county, Massachusetts, containing about 21,000, and 117 inhabitants. It is a peninsula 8 miles long, 9 miles E. of Boston, on the S. side of the harbour.

Hull, Lintb, a small island in the East Indian sea, near the W. coast of the island of Poggy. S. lat. 2° 45'. E. long. 99° 32'.

Hull of a ship is her main body, without any masts, yards, sails, or rigging.

To Hull, or lie a Hull, is under-foot of a ship, when, either in a dead calm, or in a storm, she cannot carry all her sails, but they are taken in to preserve them; so that nothing but her main, yards, and rigging are abroad, and her helm tied down to the lee side of the ship. In this state she will lie easily under the sea, if she be a good wailer, and make her way one point before the beam.

To strike a Hull, is to lie closely or obscurely in the sea in a storm, or to carry for comfort, bearing no sail, with the helm lashed a-dee.

To Hull a ship, is to fire cannon-balls into her hull, with-in the point-blank range.

Hull, in Agriculture, a term made use of to signify the chief, or hull of grain.

HULLEAH, in Geography, a town of Hindostan, in Bengal; 20 miles S. of Murzouar.

HULLOCK of a Sail, at Sea, is when, in a great storm, some small part of a sail is cut and let loose. It is chiefly used in the mizen-sail, to keep the ship's head to the sea; then all the rest of the sail is made up, except a little at the mizen yard-arm. Also, when a ship will not weather-royly, to lay her head the other way, they looae a bullock of her fore-sails, and then changing the helm to the weather-side, she is made to fall off, and to lay her head where her stern lay.

HULLUH, in Geography, a town of Hindostan, in Guzerat; 15 miles N. of Champaer.

HULME, NATHANIEL, M.D. in Biography, was born at Halifax, in Yorkshire, in the year 1732, and was bred to the profession of a surgeon-apothecary. He afterwards served in the capacity of surgeon in the navy, and being
Atointed at Leith after the peace of 1763; he embraced the favourable opportunity of procuring his medical diploma at Edinburgh, where he took his degree of doctor in the year 1765. His inaugural thesis was entitled "Differtatio Medica Inauguralis de Scorbuto." Soon after his graduation, he settled in London as a physician, intending to devote his attention particularly to the practice of midwifery. This, however, he soon relinquished; and, on the establishment of the General Dispensary (the first institution of the kind in London), he was appointed its first physician. He was also some time physician to the city of London Lying-in-hospital. About the year 1775, he was, through the influence of Lord Sandwich, then first lord of the admiralty, elected physician to the Charter-house. His other official situations he resigned many years before his death, and withdrew himself at the same time in a great measure from the active exercise of his profession; but the last he retained during the remainder of his life. In April, 1807, he was buried by a fall, which he survived but a fortnight, being at the age of seventy-five.

Dr. Hulme was the author of several dissertations; viz. a republication of his thesis, with additions, 1768. "A Treatise on Puerperal Fever," 1772. An oration "De Re Medica cognoscenda et promovenda," delivered at the anniversary of the medical society in 1777, to which a small tract was annexed, entitled "Via tuta et jucunda Calculum fulvendi in Vesica urinaria inherentem." An enlarged edition of this tract, in English, appeared in the following year, under the title of "A safe and easy Remedy for the Relief of the Stone and Gravel, the Scoury, Cyst, &c.; and for the Destruction of Worms in the Human Body; illustrated by Cases: together with an extemporaneous Method of impregnating Water and other Liquids with fixed Air, by simple Mixture only, &c."

In 1800, Dr. Hulme instituted a series of experiments on the light spontaneously emitted from various bodies, an account of which was published in the Philosophical Transactions of that and the following year. Dr. Hulme was also one of the editors of the "London Practice of Physic." See Transt. of the Med. Society of London, vol. 1, part 1, 1810.

HULPE, Le, in Geography, a town of France, in the department of the Dyle, and chief place of a canton, in the district of Brussels; 8 miles S.E. of Brussels. The place contains 897, and the canton 6244 inhabitants, on a territory of 1175074 square metres, or 11311 acres.

HULST, a town of France (formerly of Flanders), in the department of the Scheldt, and chief place of a canton, in the district of L'Echelle; 18 miles N.E. of Ghent. The place contains 1714, and the canton 11381 inhabitants, on a territory of 205000 square metres, or 20000 acres. It was formerly the capital of four offices, with twelve dependant villages: it is situated on a canal that communicates with the Scheldt, and is very strong, by its fortifications and position on the marshes. N. lat. 51° 14'. E. long. 3° 55'.

HULTSIO, a town of Sweden, in the province of Smaland; 26 miles N. of Wexio.

HULVER, in Rural Economy, a name by which the holly-tree is frequently known in some districts.

HULWAD, in Geography, a town of Hindoostan, in Guzerat; 55 miles N.E. of Wurwum.

HUMAGUACA, a town of South America, in the province of Tucumán; 65 miles N. of St. Salvador de Jagüi.

HUMAN, a town of Peru, in the province of Seroelán; 82 miles S.E. of Zareng—Alto, a town of Russian Poland, in the palmatiole of Brachut; 50 miles E.S.E. of Brachut. N. lat. 42° 42'. E. long. 30° 8'.

HUMAN, something that relates to man, or the nature of man. See Nature.

Epicurus and his followers deny that the gods concern themselves with human affairs. See Epicureans.

Faith is distinguished into divine and human. See Faith. Human Figure, The, in Painting and Sculpture. Amidst all the various beauties with which this earth abounds, and which attract the eyes and call forth the emulation of the artist, nothing is so aloofing and so engaging as the structure of the human form, and the elegance and variety of the actions of which it is capable. It has been the subject of penegyric in all ages. The naturalist, the moralist, the philosopher, and the divine, have dwelt, with holy reverence to its Maker, on its delicacy, its simplicity, yet variety of conformation, and on its intellectual and spiritual endowments; all of which are most justly combined in description, in the admired contemplative speech our own Shakspere has put into the mouth of Hamlet. "What a piece of work is man! how noble in reason! how infinite in faculties! in form and moving how express and admirable! in action, how like an angel! in apprehension how like a god! the beauty of the world! the paragon of animals!"

To the painter and sculptor no object in nature is so interesting as the human figure; none requires more study and attention to enable them justly to display its various beauties of action and expression, and a long continued series of observation and practice will alone qualify them for the fulfillment of so arduous a task.

The sources of this difficulty are, the very great latitude of its motions, and the numerous combinations of them, added to the various possibilities of view, and of light and shade. Its beauty is indeed very great, independent of all these, but they serve to enhance its value and render delightful to the artist, while they call for his utmost exertions in his endeavours to represent them. So much has already been said under the various articles Beauty, Contour, Composition, Drawing, Expression, Face, &c. that it will only be necessary in this place to treat of the proportions of the human figure, the range of its powers of action, its varieties, and the most beautiful and just combinations of them.

It has long been acknowledged, among artists, that the sculptures of the Greeks, from the time of Pericles to that of Alexander the Great, afford the best examples of beautiful and characteristic proportion; and from them a scale has been drawn out, which, if it will not serve for every purpose, will always be of use, as well to depart from, as to follow. It is, in either case, a line to guide us, and should never be lost sight of. We shall transcribe the following one from the note given by Sir Joshua Reynolds on vol. 144 of Masons's Freney.

"Learn then from Greece, ye youths! proportion's law, Informed by her, each just position draw."

"Du Fils has, in his note on this passage, given the measures of a human body, as taken by Freney, from the statues of the ancients, which are here transcribed.

"The ancients have commonly allowed eight heads to their figures, though some of them have but seven; but we ordinarily divide the figure into ten faces (this depends on the age and quality of the person: the Apollo and Venus de Medici have more than ten faces); that is to say, from the crown of the head to the sole of the foot, in the following manner:

"From the crown of the head to the forehead is the third part of a face.

"The face begins at the root of the lowest hair that grow on the forehead, and ends at the bottom of the chin."

"The
The face is divided into three proportional parts; the first contains the forehead, the second the nose, and the third the mouth and chin; from the chin to the pit between the collar bones is two length of a nose.

From the pit, between the collar bones to the bottom of the breast, one face.

From the bottom of the breasts to the navel, one face.

The Apollo has a nose more.

From the navel to the genitouries, one face. The Apollo has half a nose more, and the upper half of the Venus is to the lower part of the belly, and not to the privities.

From the genitouries to the upper part of the knee, two faces.

The knee contains half a face.

From the lower part of the knee to the ankle, two faces.

From the ankle to the sole of the foot, half a face.

A man, when his arms are stretched out, is, from the longest finger of his right hand to the length of his left, as broad as he is long.

From one side of the breasts to the other, two faces.

The bone of the arm, called humerus, is the length of two faces, from the shouluder to the elbow.

From the end of the elbow, to the root of the little finger, the bone called cubitus, with part of the hand, contains two faces.

From the box of the sholuder-blade, to the pit betwixt the collar bones, one face.

If you would be satisfied in the measures of breadth from the extremity of one finger to the other, so that this breadth should be equal to the length of the body, you must observe that the boxes of the elbows with the humerus, and of the humerus with the sholuder-blade, bear the proportions of a face when the arms are stretched out.

The sole of the foot is in length the sixth part of the figure.

The hand is the length of a face.

The thumb contains a nose.

The side of the arm, from the place where the muscle disappears, which makes the breadth, (called the pectoral muscle,) to the middle of the arm, four noses.

From the middle of the arm at the top, to the beginning of the head, five noses.

The longest toe is a nose long.

The two stopwatch parts of the tents and the pit between the collar-bone of a woman, make an equilateral triangle.

For the breadth of the limbs no precise measures can be given, because the measures themselves are changable, according to the quality of the persons, and according to the movement of the muscles. Du Piles.

The measures of the ancient statues by Audran appear to be the most useful, as they are accompanied with the outline of the figures which are most differing from for correctness.

Audran, whose work for Rosina Reynolds thus recommends, takes a different plan from that of Fresnay, and is more minutely accurate. He divides the figure into heads, each head into four parts, and each part into twelve months; which certainly has given with more accuracy the exact proportions of those figures he has measured; but Fresnay's is fully equal to the general purposes of art; for where variety of character is requisite, it is evident that the same proportions would be an evil; therefore the more general scheme is quite adequate as a guide in drawing the figure.

The knowledge of these proportions, and of the forms and positions of the bones and muscles, which compose the human figure, may be regarded as the foundation on which to proceed to the more difficult task of becoming duly acquainted with its powers and varieties of actions. A perfect knowledge of the shapes of the bones is more particularly requisite to this matter; since by their projecting parts coming in contact with each other, a limit is put to the actions of the joints; and they are secured from dislocation by the natural extensions of the muscles; and the muscles themselves directed and governed in their own actions.

Mr. A. Cadell, archer of anatomy to the Royal Academy, has able and useful lectures before that body, entered much at large upon this part of our subject, and in a very satisfactory manner demonstrated it on the skeleton and the living figure. To his kindness we are indebted for the following remarks, taken chiefly from angular measurements, and which will be found highly useful to all artists who apply their talents in the representation of the human figure.

The motions of the head and trunk of the body are limited by the several joints of the spine.

The motions of the whole body upon the lower limbs take place at the hip joints, at the knees, and at the ankles.

The great limbs, technically called the upper and lower extremities, have rotatory motions at their junctions with the trunk, by means of ball and socket joints at the shoulders and the hips.

The analogy of parts between the upper and the lower extremities is not carried throughout the structure of these limbs in the human body.

The fulcrum of the upper limb is itself moveable upon the trunk, as appears by the extensive motions of the femurs, which generally accompany the rotations of the shoulder, and which supply that limb with a greater range of movements than is possessed by the lower limb.

The junction of the thigh, with the motionless mass of the pelvis, limits its rotation to its ball and socket joints.

The rotation of the head upon the neck takes place at the joint between the first and second vertebrae.

When the nose is parallel with the sternum, the face may be turned towards each shoulder, through an angle of 65 degrees on each side, or the whole range of this turning will extend through 130 degrees.

The lateral bending of the neck is divided equally between the junctions of the seven vertebrae; but the bowing of the head, and the act of throwing the head violently backward, are principally effected, at the joint of the skull and the first bone of the vertebral column, called the atlas.

These last motions are conformable with an erect state of the neck, while the lateral motions demand a curvature of its whole mass.

The movements of the trunk are limited to the rotatory and lateral motions, which are almost equally divided among the several joints of the vertebra of the back and loins.

The joints of the dorsal vertebrae are, however, more closely compacted than those of the loins, which allows of a wider range for turning and bending in the line of the loins, than in that of the back.

The ribs and the sternum move upward, so as to expand the width of the chest at the lower margin of the ribs, and to draw the clavicles and shoulders upward: this takes place at each full inspiration of the breathing, and the contrary state follows in the act of expiration. Such apparent movements are characteristic of certain passions and actions, and are always observable in the naked figure.

In stooping, to touch the ground, the thigh-bone
forms an angle of about 55 degrees with the average direction of the spine.

"The leg bends upon the thigh, at an angle of 75°, and the line of the tibia forms with the sole of the foot, when that is elevated, an angle of 65 degrees.

"The whole of this limb is capable of moving at the hip-joint forwards, to a right angle with its perpendicular position; and backwards, to an angle of about 20°. The leg will then continue to move by itself to its own angle of 75°, with the thigh. It has, besides this, a motion outwards to about 45°.

When the shoulders are at rest, the two clavicles usually meet in an angle of 110 degrees at the sternum.

"The utmost elevation of the upper arm usually forms an angle of 155° with the spinal column, and about 125° with the line of its clavicle. The flexion of the fore arm upon the upper arm, is confined to an angle of nearly 45°.

"The whole arm is capable of moving forward or outward, through nearly half a circle, and backward to an angle of 80°, with its perpendicular situation.

"The actions of pronation and supination in the hand, range through 270°: but then 90° of the rotatory motion, in the act of pronation, are derived from the shoulder-joint.

"The palm of the hand admits of flexion and extension through 65 degrees in each direction; its lateral motions are 35° outward, and 30° inward.—The flexion of the fingers at each phalanx is 90°, or a right angle.

"These general rules govern the average and most natural actions of the living figure, but peculiar forms and acquired powers considerably change all such calculations; nevertheless it is expected in art that the knowledge of the true actions of the human figure should be derived from the general fate of nature, and not from the distortions of the posture-maker, or the acquired flexibility of the tumbler."

In drawing the joints of the limbs, considerable difference will be found in their length, according to the degree of action they are in; thus the elbow joint, when bent inwards, lengthens the arm nearly 4th. The same occurs, at the knees, and in the joints of the fingers; in the same manner as a hinge is extended when opened.

There is a very considerable difference noticeable between the joints of children before the age of 8 or 9, and those of grown persons. In the former they are small and surrounded by fat, which gives the appearance, when they are straight, of dimples in the surface; whereas, in men they are large, and always projecting; with nothing but strong tendons about them.

When the artist is fully acquainted with the proportions and capabilities of action in the human figure above-mentioned, and proceeds to represent it either in a tranquil position, or in motion, he will find it requisite to attend to the geometrical and mathematical principles on which it is constructed; and by which alone its acting powers, the muscles, are directed and governed. The due equipoise of its parts, either for its own support, or the compound admixture of the weight of other bodies, in lifting, pulling, pushing, &c. must be carefully regulated, or in vain will he attempt to effect his object. The following observations may be found useful on this subject.

When a man is entirely at rest, and standing equally on both feet, a line drawn perpendicularly from the pit between the clavicles will fall exactly in the midway between his feet.

If he moves, so as to stand upon one foot, it will fall upon the heel of that foot.

If he raises one arm, it will throw as much of his body on the other side of the perpendicular, as is equal to the weight of, and is necessary to counterbalance, that arm.

If one of the legs is thrown back, the breast is brought forwards, so as equally to bring the centre of gravity of the whole frame always in the same relative situation to the parts, in every position in which the body can be thrown.

Thus the equipoise of the figure is of two parts, simple and compound. Simple, when a man acts only by and upon himself; and compound, when any external weight be superadded; for that must be regarded in his actions, while suspending it, as a part of his own frame; and in order to lift or support it, he must throw as much of his own weight in a contrary direction on the central line, to that where the object is applied, as is equal to it; or it will overpower and draw him to the ground. Indeed it will be necessary, in lifting, to throw a larger proportion of weight or muscular force over, or it cannot be effected.

In action, the same principle governs the figure. Having, by the motion forwards of one part, in walking for instance, removed its centre of gravity, it endeavours, in the instant, to recover the balance lost, and brings up another to support itself; and these actions, going on progressively, carry it forwards. In running, a greater impetus is given; the breast is thrust farther forwards, and a quicker application of the support of the limbs is required; thus, the flower the motion, the nearer the support will be under the centre of gravity; and on the contrary, when the motion is quickened, the farther it will be removed from it.

When a man intends to strike a severe blow, he endeavours to add the weight of his body to the force of his arm, and to effect this he draws back himself over the perpendicular to a considerable distance, then, rushing forwards while he strikes, conveys his body as far on the contrary side.

Thus, the motions of the figure must be always regulated by its centre of gravity; the perpendicular of which is its centre of motion. The motion being created by the lofs of equipoise, or inequality of weight, will, of course, be more or less violent, accordingly as a greater or less proportion of the body be removed from the perpendicular.

With regard to the muscular action of the figure, the plates of anatomy, and the decriptions given under that article, will sufficiently inform the reader. Each muscle has its individual or conjoint power and use. It is the artificer's duty to felect, in representation, those which more immediately are employed, and characterise, an action; and not to make too great a display of anatomical knowledge, nor at all times, and in all the various actions of the human figure, represent the same muscles (when seen) with the same degrees of force, that is, equally tense; as if their power was requisite in every action; as is frequently the case among the imitators of M. Angelo. No matter how the man was employed, every muscle throughout the frame is rendered equally prominent; and the eye and the understanding bewildered, in endeavouring to comprehend what part was principally in motion. But more of this when we treat of Style, in Design; see that article.

HUMAN FOSSIL-REMAINS, in Natural History. With early writers on natural history and geology, it was no uncommon thing to refer almost any large uncommon bones, which were met with in the earth, to giants of the human race. The pretended parts of a human skeleton by Schweizer, found in the date-pit at Oningen, his anthropolith, proteus, &c. are shown in the Annales du Musæum, vol. xiii. p. 411, to belong to a kind of lamassuer, and at page 198, the pretended human fossils of Cèrigo are shown to be devoid of that character. After all which has been said on the human bones found
Found in the offeens rock of Gibraltar (Jones, Phyl. Disq. p. 428.), and other places in the Mediterranean and coast of Dalmatia, the fact of their having any of them belonged to the human race may fairly be doubted. The arm and skeleton of a man, mentioned by Mr. Chariton, in his History of Whitsby, p. 335., as found in the alum shelves, were probably no such thing. The tooth which Mr. Jones mentions as having been discovered by the laundress, if really human, have been taken from some church-yard, or ancient burial-place, whose waters were of a petrifying quality, as well as the woman's hand which he mentions, p. 437. If such was not a mere deception, owing to the external form, like the pretended leg and foot of a child in black flint, which we have seen, that was taken out of a chalk-pit. The human tongue, or glossopetra of Plieny, and the human thigh of stone mentioned by Parkinson. (Org. Rem. p. 16 and 21.), and the two bones of a man's foot in iron-bone, which Dr. Grew mentions (Rarities, p. 332.), were probably all deceptions of a similar kind; and to one or other of these classes, see. It, mithlitn animal remains; or, 2d, deceptive forms of mineral nodules, may, perhaps, all the supposed human relics, found imbedded in the strata, be referred. A 3d class of human remains may be admitted with less hesitation, viz. bones found intermingled with modern herbal deposits or fuls, like the human ribs found along with a boat, under a flcy or concreted gravel stratum, near Petersburg (Kirwan's Geo. Efl. p. 442.), the skeleton found with beads, rings, armours, coins, &c. mentioned by Mr. Whitehurst (Inquiry 1st Ed. p. 15); and by many other writers, but which clearly did not belong to the stratiﬁed remains. A 4th class of human reliquia are found preferred in peat-bogs, some instances of which are said to occur in the peat-pits near Newbury. (Phil. Trans. vol. i. p. 19.) A woman preferred in a bog at Axholme, in Lincolnshire, and a man in a bog in Shetland (Jamefon's Shetland Isle, p. 158.), and various similar instances, which are to be met with. Mr. William Martin, in combating the arguments formerly advanced to show that the supposed human animal, and vegetable remains of the strata were depoited at the Noachian deluge, or by parts of its waters left in inland lakes and seas, observes (Outlines, p. 56.), "According to facies, history, the title, date of the ancient kingdom, as well as the vegetable, had taken place, long before the period in which they were equally involved in one general inundation. And hence, in strata imposed to have been formed by depositions from water left by the deluge, not only might we reasonably expect to ﬁnd vegetable and marine relics, but also the remains of land animals, of quadrupeds for instance, and even of man himself. For, however small a proportion the destroyed land animals bore among the general multitude of organic bodies overwhelmed by this catastrophe, as they did exist, and as the bones of quadrupeds are certainly as liable to subﬁdence in water as drifted timber or other vegetable matter, they no doubt would occasionally be met with in the strata in question, if such strata had really originated from the caufe assigned in the hypothesis. But, on the contrary, it is an indubitable fact, that neither the remains of man nor of quadrupeds have ever been found in ﬂnites or earths constituting strata producible of genuine mineral coal, nor indeed as integral parts of any strata, excepting those which are decidely of much later formation, such as we are now treating of. To a far remoter period, therefore, than the ﬂood, must we recur, in any endeavour to explain or illustrate the agency of nature, in collecting and depositing the minerals of regular disposed strata."

HUMANAMENTE, in Geography. a town of New Mexico; 63 miles S.S.E. of Santa Fe.

HUMANITY, the nature of man, or that which deno-
mimates him human.

Neatorium would not allow the inﬁrmities of humanity to be attributed to the Deity; nor the attributes of the Deity to humanity. See NEHITIANS.

HUMANITIES is the culturably, for the humanitas liberalis, i.e. the study of the Greek and Latin tongues, grammar, rhetoric, poetry, and the ancient poets, orators, and historians.

HUMANAR, in Geography, a small island in the Red Sea, near the coast of Arabia; three miles N.W. of Lobeia.

HUMARES, a town of New Navarre; 120 miles S. of Cede Grande.

HUMAS, an Indian village on the W. side of Missipii river, in Louisiana, 60 miles above New Orleans. The Humans were formerly a considerable nation, but were reduced, about the year 1770, to about 25 warriors. The Ahoonas, whose villages are near those of the Humans, had at the same period about 30 warriors. See BURIAL.

HUMAXAR, a town of South America, in the government of Tucuman, on the river Dolce; 60 miles S. of St. Jago del Elera.

HUMATION, HUMATIO. The most ancient way of disposing of the dead was by humation, or interment. Phiis. See BURIAL.

HUMBER, in Geography, a river of England, or rather a large estuary, formed by several considerable rivers, and efpecially by the Ouse and Trent, and flowing into the German ocean, N. lat. 52° 30'. E. long. 1° 15'. Besides the Trent, which enters the Humber after a direct course of about 100 miles, and which is navigable to Burton, in Staffordshire, and the Ouse, which runs by York, and is navigable to Rippon, the other principal rivers that ﬂow into the Humber are the Don, which runs by Doncaster; the Aire, navigable to Leeds; and the Calder, navigable to Halifax; the Wark, navigable to Tedderley; the Derwent, navigable to New Malton; and the Hull. See CANAL.

HUMBER, a river of Upper Canada, in the E. riding of the county of York, which discharges itself into lake Ontario, 51 miles N.E. of the old fort Tonton.—from a river of Newfoundland island, which runs into the gulf of St. Lawrence, through the bay of Islands.

HUMBERSTONE, a township of Upper Canada, in the county of Lincoln, lying between Bertie and Wainfleet, and fronting lake Erie.

HUMBERT, in Biography, a cardinal in the 11th century, a native of Lorraine, embraced the monastic life in the diocese of Toul, in the year 1012. Here he acquired a high reputation for talents and learning, that pope Leo IX. sent for him into Italy, where he promoted him to the bishopric of the White Forest. In 1034 he was raised to the purple by the same pope, who sent him his legate to Constaninople, to attempt to restore the ancient union between the eastern and western churches. In 1059 by the order of pope Nicholas II, he drew up the confession of faith for the famous Berenger to sign, in which he laid down the monstrous doctrine, that "the bread and wine, after confection, were not only a sacrament, but the real body and blood of Jesus Christ; and that this body and blood were actually handled by the priests, and consumed by the faithful, in reality and truth as other edible objects are." Cardinal Humbert died after the year 1069. His works are numerous and chiefly theological. Moreci.
HUM 

HUMBLE-Bee, in the History of Insects. See DOMESTICUS.

Humble-bees, Beesard. See FAUX bourdon.

Humble-bee Flies, in Natural History, the name of a class of flies of different sizes, but all agreeing in the great resemblance they bear to the humble-bees, of the smaller or middle-sized species. There are two kinds, very natural paths for real humble-bees; but a closer examination will show them not to be such, as they have not the trunk of the humble-bee, and have only two wings. The species of the humble-bee fly are many of them of absolutely different genera one from another, some of them having trunks, and others having a distinguishable mouth. See CULEX.

If the figure of these flies, in their winged state, attracts our curiosity and attention, their prior state, that of the fly-worm, of most of them caught surely much more to do for. The place nature has assigned the worms of these flies for their habitations is, in fact, a sort strange one; there is no other place for them to live in under this form, to begin their defined growth, and be fitted for their transformations, but in the interstices of horses, or under the thick and firm skin of oxen. In the latter case, the worm hatched from the egg of its parent fly, deposited there, makes the tumour in the place which alone furnishes it with food and habitation, and in the middle of which it has a place to breathe. See HIPPIDOMS.

It is not an invariable law of nature, however, that all the worms of the humble-bee flies are to feed on animal substances; for we find some delighted with vegetable food, and particularly one which loves none but the bulbous roots of flowers. Reanum's Hill. Inf. vol. iv. p. 497, &c.

HUMBLE-Planis, in Gardening. See MIMOSA.

HUMBLED, in Rural Economy, a term that is frequently applied to neat cattle and sheep, in order to denote their being hornless.

1. H. laurifolia. (Botchius laurifolia; Vahl. Symb. f. 3. 39. t. 66.)—Native of Ceylon. A tree with jointed, zigzag, hollow branches. Leaves abruptly pinnate, of four or five pairs of flaked, ovate-oblong, pointed, entire leaflets. Stipules double; the outer ones horizontal, half arrow-shaped; the inner ovate, pointed, erect, much the largest. Clusters of many flowers, axillary, solitary, or in pairs. Willd.—denovd.

HUME, David, in Biography, an eminent historian, was born at Edinburgh in 1711. He was the youngest son of a man of good family, who died while David was in his infancy, so that his education was entrusted to his mother. He displayed, at a very early period, a great love for literature, which became his predominant passion. His patrimony was too slender to permit him to follow his inclinations without some view to profit, and he attempted to gain some commercial employment at Bristol. In a few months he found that kind of business totally unsuitable to his genius, and went to France with the intention of prosecuting his literary pursuits in a country retreat, resolved to supply by economy his pecuniary deficiencies. He resided at Rheims, but chiefly in Anjou, and passed three years very agreeably in that kingdom. In 1737 he came to London, and in the end of the following year published his "Treatise on Human Nature," which he had composed during his residence in France. Mr. Hume's ardent passion for literature received a severe mortification from the neglect attending his first publication, which appeared and was sold almost in the same month without reaching such distinction as even to excite a murmur among the zealots. He did not despair, but proceeded in his studies, and in 1742 printed his "Essays, Moral, Political, and Literary." These were so favourably received as to make the author amends for his former disappointment. In 1745 he received an invitation from the young marquis of Annumdale to come and live with him in England. This connection halted but a single year, when he fled forward as candidate for the professorship of moral philosophy in the university of Edinburgh, and was powerfully supported by persons of consideration and high rank. He was, however, unsuccessful. General St. Clair, in 1746, nominated him his secretary in an expedition designed for Canada, but which ended in an attack upon the French coast. In 1747 he attended the general, in the same station, upon a military embassy to the courts of Vienna and Turin. On his return, he re-published his piece on human nature, with alterations, under the title of "An Enquiry concerning the Human Understanding." It was scarcely more successful in this form than it had been before, but his other works were beginning to attract notice, and make their way rapidly. In 1752 he published his "Political Discourses," which were received with immediate approbation. In the same year his "Enquiry concerning the Principles of Morals" was published, which he considered as the best of all his writings, but which met with little notice. He obtained, in 1752, the appointment of librarian to the Faculty of Advocates in Edinburgh, which afforded him the command of a large and curious collection of books. It was this circumstance which seems to have inspired him with the idea of becoming an historical writer, as it was probably his local situation which suggested to him, as his first subject, the "History of England under the House of Stuart." The first volume, containing the reigns of James I. and Charles I. appeared in 1754, which was furiously assailed from all quarters, on account, as he thought, of what he had said in defence of the earl of Stratford; but it was probably owing to his undisguised contempt for all religions, of which he recognizes but two species, superstition and enthusiasm. This work was so completely neglected as well as decried, that, had not a war broken out between England and France, he would probably have retired to some provincial town of the latter kingdom, have changed his name, and for ever renounced his country. The second volume of his history, comprising the period from the death of Charles I. to the Revolution, appeared in 1756, and was received much better than the first had been. With this encouragement he published his history of the house of Tudor in the year 1759, which excited against him a renewed portion of rancour. His reputation as an historian continued to gain ground, so that he was induced to go back to the earlier periods, and write down to the point at which his last work had commenced. These two additional volumes appeared in 1761, and his history of England thenceforth became a standard book, read by all, at home and abroad, who wished to take a comprehensive and interesting view of the English affairs. The researches of Mr. Hume into the origin of the constitution are not remarkable for depth or accuracy; and he seems too ready to admit the idea that the liberties of the country are of modern date, and were so many forced concessions from the sovereigns,
In his history of the Tudors and Stuarts there seems a manifest design of exaggerating the deportment of the former, in order to lighten, by comparison, the usurpations and high pretensions of the latter. His style is clear, lively, sometimes eloquent, always agreeable, though not unfrequently careless and incorrect. The money which Mr. Hume obtained for the copy-right of his history, joined to a considerable pension granted him by the crown as a literary man, had now secured him an independence, with which he intended to retire to his native country, but in 1763 he received an invitation from the earl of Hertford to attend him on an embassy to Paris; and his character as a writer and philosopher being well known in that capital, procured him an excess of attention and civility, with which he was highly delighted. He remained at Paris as "Chargé d'Affaires," after the departure of lord Hertford in 1765, and did not return to England till 1766, when he brought with him the celebrated Rouleau, who, having excelled everyone else in every country near him, was induced to seek for an asylum in the only true land of liberty. Mr. Hume's conduct towards his friend was extremely kind and generous; but so capricious was the temper of Rouleau, that he fancied all the world was leagued against him, and betrayed such groundlessness and unworthy suspicions as finally dissolved their friendship. In 1767 Mr. Hume accepted the office of under-secretary of state, which he held under general Conway till the relinquishment of that minister in 1769. He then retired to Edinburgh, expecting to enjoy a comfortable old age by means of the friends, the reputation, and opulence which he possessed. In that northern metropolis he drew around him a chosen circle of suitable associates, with whom he lived upon easy and very familiar terms. He died in 1776. The account which he has given of his last illness is as follows: "In spring, 1775, I was struck with a disorder in my bowels, which at first gave me no alarm, but has since, as I apprehend it, become mortal and incurable. I now reckon upon a speedy dissolution. I have suffered very little pain from my disorder; and what is more strange, have, notwithstanding the great decline of my person, never suffered a moment's abatement of my spirits, inoffuch that were I to name a period of my life which I should most chuse to pass over again, I might be tempted to point to this later period. I perceive the fairest adornment as ever in my day, and the fairest glory in company, I could have beheld. At a man of 65, by dying, cuts off only a few years of infirmities; and though I see many symptoms of my literary reputation's breaking out at last with additional luster, I knew that I could have but few years to enjoy it. It is difficult to be more detached from life than I am at present." The account of his own life, of which the foregoing is an extract, was dated the 16th of April 1776, and he gradually grew worse till August the 25th, when he died in the 67th year of his age. His character has been drawn by Dr. Adam Smith: "He was one" says he, "concerning whom philosophical opinions men will, no doubt, judge variously, every one approving or condemning them according as they happen to coincide or disagree with his own, but concerning whose character and conduct there can scarcely be a different opinion. His temper indeed seemed to be more happily balanced, if I may be allowed such an expression, than that perhaps of any other man I ever knew. Even in the lowest state of his fortune, his great and necessary frugality never hindered him from exercising, upon proper occasions, acts both of charity and generosily. It was a fragility, founded not upon avarice, but upon the love of independency. Upon the whole, I have ever considered him, both in his life-time and since his death, as approaching nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit." To this picture, drawn by the pen of a judicious biographer, we may add the observactions of a very literary friend. "We may," says he, "reasonably deduce to Dr. Smith's moral estimate, in attributing the perfection of virtue to a man whose leading principle was, by his own confession, selfish (the acquisition of literary fame), and who never seems to have made any of those sacrifices of interest and inclination to public good, in which virtuous action so clearly consists. Further, whatever degree of freedom of discussion may be justifiable, with the benefit of mankind in view, it may be doubted whether a mere fondness for speculation, or a love of philosophical applause, will morally excite a writer for sporting with opinions which are commonly held of the highest importance to human welfare." Two of his posthumous works were published after the death of Mr. Hume, viz. "Dialogues concerning Natural Religion," and "Effays on Suicide." The latter contains some of his most obnoxious principles, conveyed in the most offensive form. See Hume's account of his own life, and Dr. Smith's letter prefixed to the 8vo. edition of the History of England 1789. Gen. Biol. HUMEA, in Botany, so named, by the writer of the present article, in just commemoration of the late right hon. lady Amelia Hume, sister of the present earl of Bridgewater, and wife of sir Abraham Hume, bart. who, after raising this plant in England, and communicated it to him. Her ladyship for many years cultivated successfully, and studied scientifically, a fine collection of plants, at her seat at Wormleybury, Herts, and was always distinguished by the liberality with which she imparted to others her acquisitions or discoveries. She departed this life, admired and beloved by all who knew her, in September, 1809, and is interred at Wormley—Sm. Exot. Bot. v. 1. 1. (Calomelia; Venten. Jard. de la Malmaie. 73.)—Clafs and order, Syngenea Polygama-equalis. Nat. Ord. Composite Dicoidae. Lima. Cerebhyrids. Suff. Gen. Ch. Common Calyx of numerous, imbricated, obo- vate, obtuse, concave, coloured, pointless scales, the outer ones small and gradually more dil. Cer. comp. uniform, tubular, of very few florets, whole proper corolla has a cylindrical tube, and a bell-shaped limb, with five reduced segments. Stam. Filaments five, capillary; anthers united into a pentagon, with five sharp teeth. Pyl. German oblong, glandular, style cloven; frugias spreading, calypus. Peric. none, except the permanent furrowed calyx. Seed oblong, without any crown or wing. Recept. very small, glabular. Eff. Ch. Receptacle minute, glandular. Down none. Calyx leafly imbricat, membranous, pointless. Florets about three. Anthers awned. 1. H. elegans. Sm. Exot. Bot. t. 1. (Calomelia amaranthoides; Venten. Jard. de la Malmaie. t. 73.)—Native of New South Wales, not far from Port Jackson, from whence we received specimens amongst the first plants sent from that country in 1791. The root is biennial. Stem herbaceous, five or fix feet high, erect, panicled, round, filled with spongy pith, and rough (like the leaves) with short rigid viscid pubescence. Leaves alternate, sessile, lanceolate, acute, from six to twelve inches long, slightly veined at their edges, and clasping the stem by their heart-shaped bases, of a full green colour on both sides, and furnished with a midrib, with conspicuous reticulated veins; the upper leaves gradually diminish into bracteas of a small lanceolate figure. Panicle drooping and widely spreading, of innumerable small pendulous flowers,
HUMIDUM Radicale, or Radical Moisture, in the pathology of the ancient philosophers, a supposed principle in the animal economy, which, together with the radical heat, was essential to life, and constituted the vital energy. The principle being altogether gratuitous, different notions were formed concerning it by different writers; and some confounded that they did not understand what was meant by the terms. See Semmert, lib. i, cap. 5. De Calido in nato et. Humido radicale. Fernel, lib. vi, cap. 4, entitled "Humidi primum, quod tum calorium tum spiritus subjecta est materia, demonstratio."

HUMILIANI, a congregation of religious in the church of Rome, established by some Milanese gentlemen on their release from prison, where they had been confined under the emperor Conrad, or, as others say, under Frederick I. in the year 1162. This order, which acquired great wealth, and had no less than ninety monasteries, was abolished by pope Pius V. in 1570, and their houses given to the Dominicans and Cordeliers, for their luxury and cruelty.

HUMILIALION, the act of humbling, i.e. of abating a person's pride, and bringing him lower in his opinion.

In this sense, humiliation stands distinguished from mortification: humiliation brings down the mind; mortification banishes the flesh.

HUMILIS MUSCLES, in Anatomy, a name mentioned by Catterius, as given by some people of his time to one of the muscles of the eye, the rectus inferior of Fabricius, and deprimens of Riolan; it is the depressor oculi of Albinius, being one of the quatuor recti muscles oculorum of that author. See Eye.

HUMILITV, in Ethics, is a virtue consisting in the moderate value which a person puts upon himself, and every thing relating to him. Or, more particularly, it consists in not attributing to ourselves any excellence or good which we have not; in not over-rating any thing which we have or do; in not taking an immoderate delight in one's self; in not assuming more of the praise of a quality or action than belongs to us, and in a lowly sense and acknowledgment of our imperfections, errors, and sins. This virtue expresses itself in the modesty of our appearance, of our pursuits, and of our behaviour towards other men. It is distinguished from affectation, bashfulness, and mean-spiritedness.

HUMISUGA, the Ground-fowler, in Natural History, the name of a fly, so called, because it is supposed to live by sucking the juices of the earth, without taking in any solid food. It has a brownish or dun body; a white spot at the inferior of the wings, and another at the head; the legs are black; the back is grey, with four fullled white lines running longitudinally; the wings are silver, and, if put into water, they shine with a bright light like that of the glow-worm. This creature is common with us about path-ways, on mole-hills, and in other places where the ground is newly turned up. We call it the path-fly.

HUMMEL'S TOWNS, in Geography, a thriving town of America, in Dauphin county, Pennsylvania, containing a German Lutheran church, and about 90 houses, on the S. side of Swatara creek; 100 miles W.N.W. of Philadelphia.

HUMMET, The, a small island in the English Channel, near the N.E. coast of the island of Guernsey.

HUMMING-BIRD, in Ornithology. See Trochilus.

HUMMOCK, in Geography, a small island in the East Indian seas; 15 miles S. of Mindanao. N. lat. 5° 24'. E. long. 126° 37'.

HUMMOCK Point, a cape on the N. coast of the island of Cebes, so called by captain Carteret in 1767, who supposed...
HUMmock, a term used by Navigators to express circular and elevated mounts, appearing at a distance.

HUMMUDNAGUR, a town of Hindoostan, in E. Har; 45 miles S.S.W. of Patna.

HUMOR, or HUMOUR. See HUMOUR.

HUMOR, in Geology, was introduced by M. de Luc, "Elementary Treatise on Geology," p. 55, and defined to mean water, not as a compound of hydrogen and oxygen, but as an elementary substance of the globe, distinct from the forms of water, ice, (or crytalized water,) or steam: suggesting, says he, that "in its primitive state, when nothing of what we now observe upon the earth was produced, nor as yet dispersed to be produced, this substance (humor) was neither water, nor ice, nor aqua; its elementary particles were intermixed with all those to which they are at present united by affinity, in the different bodies with which we are acquainted; and these particles, then acquiring liquidity by their union with fire, and thus immediately entering into all the associations, to which its numerous affinities gave birth among elementary substances, produced the Primordial Liquids; which see.

HUMORAL PATHOLOGY, that pathology, or doctrine of the nature of disease, which attributes all morbid phenomena to the disordered condition of the fluids, or humours, of the body, and attempts to explain the progress and changes of diseases by certain fermentative or digestive operations in the humours.

In many of our articles on medicine we have had occasion to allude to the humoral pathology as the foundation of many opinions and peculiar modes of practice, which a more accurate pathology has confuted and exploded. It would be a fruitless labour to enter into a minute detail of all the absurd speculations respecting the morbid changes in the fluids of the body, which have been successively adopted, from the time of Galen downwards: for, not only the followers of Galen, but all those in modern times who have disserted from his opinions, and have transferred the doctrines of chemistry and of mechanics to the phenomena of the living body, have, nevertheless, admitted the changes of the fluids into their sylphs, as the principal causes of disease, and as the foundation for explaining the operation of medicines: nay, even after the peculiar property of living bodies, (the faculty of irritability, excitability, sensorial power, or nervous energy, as it has been variously denominated,) which is resident in the nervous sytem, came to be viewed as a principal agent in the production of disease, and in the restoration of health, according as it is influenced by morbid caules, or by salutary impressions; or when, as Hoffmann first maintained, (Medicin. Rational. Syst. tom. iii. § 1. chap. 4.) the affections of the living solids came to be admitted as the most probable grounds of disease, and as affording a more rational explanation of morbid phenomena, than the disordered conditions of the fluids; still a humoral pathology was received, and combined with these opinions, to a considerable extent. Dr. Cullen himself, who advanced far beyond Hoffmann in his appeal to the agency of the living solids, occasionally refers to certain supposed "scenery of the fluids," as the essence of some diseases; and it was in the sylphs of Brown and Darwin that all consideration of the changes of the humours, as the origin of disease, was first rejected, and every morbid condition was referred to the agency of that power, the nervous energy, which distinguiishes the living body from dead matter. (See Excitability and Irritability.) But the doctrines of the older physicians continue to be, in a great measure, the prevailing opinions of the vulgar, if not of the generality of unprofessional persons, and even of a great number of routinists in the profession.

We
HUMORAL PATHOLOGY.

We shall, therefore, briefly state the principles of those doctrines, and shew the futility of the arguments on which they rely.

The four elementary humours of Hippocrates and Galen, namely, 

\textit{phlegm, blood, bile, and black bile (melancholia),} were received as the principles of all the animal fluids and solids, constituting by their due proportion the health of the body, and by their \textit{intemperies,} or undue proportion, the varieties of disease, until the time of Paracelsus.

This bold and conceited chemist, who set up for a reformer of all philosophy, renounced the system of Galen, denied the existence of the four humours, and contended that liquid properties were not produced by humours, but that humours originated from diseases.

At the same time he promulgated a system of his own, using a Jargon which is not very intelligible, and to which it may be questioned whether either himself or his followers ever attached any clear ideas. He adopted the notion of three elementary substances, to which he applied the appellations of \textit{fals, sulphur, and mercury,} with Ball, Valentine, and others; but those terms were employed in new acceptations, about which the chemists were not altogether agreed. They are to be considered, it would appear, as general expressions of some faculty or property, which they communicate.

Thus mercury appears to represent the principle of fluidity, sulphur that of indissolubility, and salt that of solidity. According to Severinus, one of the followers of Paracelsus, "sulphur gives fluidity, fluidity, or conglutination to things; mercury imparts a fat oleaginous quality, which tempers the constitution of the salt; and mercury gives fluidity to both, and facilitates their mixture." And Quercetanus, another writer of that school, says that things receive their various taints from fals, their odours from sulphur, and their colours from both, but chiefly from mercury.

(See Sennert. Tract de Confinen et Diffinis Galenicorum et Peripatet. cum Chymicis. cap. 11.) They speak also of animal sulphur, vegetable sulphur, and mineral sulphur; of animal salt, vegetable salt, &c.; so that it is obvious these were merely gratuitous and hypothetical expressions, which every one might use according to his own fancy, and which led to every species of absurdity. When they treat of the origin of diseases, this absurdity is manifest throughout. Paracelsus lays down two genera of diseases, one of which he calls, in barbarous language, \textit{thalfum, the other \textit{corpusculum;}} the former including those disorders which grow from seed, like apples and nuts,\textsuperscript{1} such as dropsy, jaundice, &c.; the latter those which arise from corruption, such as fevers, the plague, &c.

(Parac. Labyrinth. Medic. err. cap. 11.) We should consider our time, and that of our readers, as lost in examining the minutiae of this sylleptic jargon. If curiosity should impel any one to investigate the subject, he may peruse the various writings of Paracelsus himself, or Schernemann's "Hydromantia Paracelsiana," and "Medicina reformata;" as well as Quercetanus's "Hermetica Medici Defenso," the works of Oswald Crollus, of Peter Severinus, &c. Sumner has attempted to refer the jargon of these chemists to the Galenical doctrines, from which, where it is intelligible, it seems to differ more in appearance than in essence; for it ultimately refers diseases to various conditions of the humours, which are elucidated by the appearances and sensible qualities of the excretions and discharges, changing only the terms by which they are designated.

(Loc. cit, cap. 16.) See Galenical System.

As the study of chemistry advanced, and its various operations and products were investigated, pathologists began to modify the doctrines of Galen generally, and, laying aside the four humours of that writer, they designated the various humours, connected with different flates of diseases, according to analogous properties, fancied or real, in these morbid humours, and in the substanices with which chemistry had made them acquainted. Thus we find the writers of the 17th century speaking of mucilaginous acid, vitriolic, tartraric, alkaline, corrosive, and acid humours, of a saline, putrid, rancid acrimony, &c.; (see Sir J. Floyer's "Preretr natural State of Animal Humours described by their sensible Qualities, &c.")) and likewise attributing much to the agency of the \textit{spirits}, or animal spirits, which they seem to have confedered as a secretion from the brain, communicated through the canals (as they were supposed to be) of the nerves, and constituting the most "exalted" portion of the animal humours. Our countryman, Willis, substituted this term for the \textit{mercury} of Paracelsus, and speaks of the \textit{fals, sulphur, and spirits,} as the three principal elements of the humours, to which he likewise adds \textit{earth} and \textit{water.} (Willis, Diatriba de Fermentatione, cap. 2. et de Febribus, cap. 1.)

The humours of Galen, he contends, are not parts of the blood, but its reagents; the blood, properly so called, being the same in every part of the body, and the \textit{fals}, bile, and black bile, being the impurities thrown off by it, by means of a sort of excrement or fermentation. In like manner, he observes, in the case of the fermentation of wine or porter, the lighter parts ascended to the top, forming the \textit{flato or yeast,} and the thicker parts fell to the bottom, in the shape of dregs or tartar; leaving the liquor clear; yet to one, he says, could correctly affirm, that wine or porter is composed of yeast, tartar, and a vinous liquor.

But whatever notions pathologists have at different times adopted, in regard to the number and qualities of the elementary principles of the humours, they have all agreed in explaining the phenomena of diseases, by a certain intelline process, which has been variously compared to digestion, fermentation, effervescence, or ebullition, by which the humours were supposed to be purified, in consequence of the expulsion of the offending matter. The ancients considered this deputatory process as analogous to that of the digestion, or concoction (as they termed it) of the food in the stomack. For the various substanices, taken into the stomack for the purposes of nutrition, became gradually converted, by the process of concoction, which was carried on by the innate heat, into a bland homogenous fluid, the chyle, which was absorbed by the metenteric vessels for the nourishment of the body, while the dregs or fasses were carried off by the bowels, and discharged; in like manner they supposed that when the blood was in a state of intemperies or dyspepsy, the constitution was excited to fermentation, during which a sort of fermentation, or digestive process, was carried on, and the blood, being thus depurated, the morbid humours were discharged by some of the usual excrementitious passages, the bowels, the bladder, the vesicles of the skin, &c. When this discharge, whether a diarrhea, a sediment in the urine, a profuse periperrition, &c. took place, a \textit{crista} was said to occur; and the purpose of the febrile commotion having been effected, the constitution ceased from its inordinate action, and health was restored. (See Concoction and Crisis.) These discharges, with which it is observed that fevers often terminated, were considered as the proofs of the existence of the morbid humours in the blood, and of the origin of the febrile commotion, which continued while they were retained in the body, and ceased when they were expelled.

After the revival of learning, when chemistry had made some advances, the process of fermentation was more commonly affirmed, as explanatory of the nature of febrile diseases. The physicians of the 19th century, Willis, Floyer, and others, referred all the phenomena of acute diseases to this source; and Sydenham acknowledges a great analog}
HUMORAL PATHOLOGY.

In the two processes, yet remarks that the analogy is not perfect, and therefore prefers the term connection to that of
fermentation or putrefaction, which other writers employ. (See his Obi Med. § 1. cap. 3.) It is to be remarked, however,
that the term "fermentation," in the acceptance adopted by Willis, signifies every species of chemical action,
combined, or change in the operations of animal and vegetable nutrition and growth, by which unorganized
matter is assimilated with living bodies. (See his Diatribe de Fermentation.)

During the 17th century, then, or rather from the latter part of the 16th century, nearly to the time of Dr. Cullen,
the process of fermentation was considered as constituting the essence of all febile diseases; and as fermentation, in
regard to the production of vicious liquor, is excited commonly by some ferment introduced for that purpose, so a ferment
was supposed to have found its way into the blood, when the animal system was excited into a fermentative or connection
and thus the blood was depurated, and the peccant matter expelled, or separated, like the dregs of wine. This
ferment, or cacochymy, was accounted for in various ways; as from asylum ways; but we may collect, on the whole, that
they maintained the notion of two principal internal focires of cacochymy, namely, imperfect food, and imperfect infection
from the different glandular organs. Ferrenchus remarks,

"Omnes enim cacochymiae et humorum impuritas aut ex vitialis vifcerum afficitione, aut ex improba vivendi ratione, non alius ex caulis, proficiscitur:" for, he adds, when the stomach, liver, spleen, and neighboring organs, are diseased, either by intermittent or organic disorder, they produce humours, similar to diseased, even from pure and temperate aliment; and, when the food is immoderate, heavy, glutinous, or corrupted, it cannot be wholly and perfectly changed by digestion, as not to carry some of its crude or unwholesome quality with it to the blood and other humours. (See Fernal. Febr. Curand. Methodus Generalis, cap. 2.) In like manner, Willis observes, "Atque haufiunotus motus (animarum funguris verit intellectum bellum) dependet tunc a partium phlegm fanguinis heterogenetate, tum a variis fermentis, quia a vifeeribus crucuris malle insipientur." (Diatribe de Feb. cap. 2.) It may be remarked, by the way, that in thus referring some of the morbid humours to the viscera, they seem to admit, though unintentionally, the primary action of the solids in the production of disease. In general, however, they looked to the conception or fermentation of the aliment into chyle, as the source of the cacochymia; and Sir John Floyer considers all the internal variations of the humours as originating from a defect in or excess of degree of the fermentation by which nutrition is carried on. "If the chyle be rightly fermented, all the humours arising from it are rightly prepared; but if the fermentation of that is vitiated, all other the humours, produced from vitiated chyle, retain a tincture of its defect in their preparation. This fermentation, by which the chyle and blood are prepared, may be depraved both ways; for it may be deprived under its natural state, or excited above that degree, which is suitable to the natural temper of any animal; of both of which errors, and the cacochymas depending on them, I shall next discourse." (Loc. cit. p. 34.) He then informs us that if the animal humours are digested or fermented "to any degree below their natural state, some of the cold cacochymias are produced." Amongst these he enumerates a mucilaginous or putrid, a tartarous or acerb, a flatulent, and a fecous state of the humours. If the chyle be ever-digested, or digested too much; "it becomes bitter, acid, rancid, or putrid;" it also produces a vefid state of blood, which occasions pain and inflammations, and seizes itself in the febris of blood that is drawn in inflammatory diseases; as well as a flat acrimony, which corrodes and cuts the gums, infects the skin with spots, and is the hoar fever." (Ibid.) These various species of cacochymia, then, are termed fermenta, by which the blood is excited to violent fermentative conjunctions, or fever. But there are other diseases, "which depend wholly on an outward ferment received into the flesh, as in hydrophobia," or arise from the poison of serpents, or from "the touch of a flat humour to which the morpheiws, scab, pus, and scald-head are referable, and leprous;" and "all malignant fevers, as the small-pox, measles, and plague, or pestilential fevers, have their original from the malignity of the air, and the poisonous sulphurs of the earth." (Floyer on Febriferal. State of Humours, p. 15.) In like manner, Sydenham ascribes all epidemic diseases to a ferment, poison, or peccant matter, introduced into the blood by respiration, the air inspired being impregnated with this poison, either from the bowels of the earth, or from some peculiar influence of the planets. While he attributes sporadic febile diseases to the putrefaction or inflammation of the blood, occasioned by the peculiar intemperance of individuals, which he seems to impute chiefly to the influence of external temperature, and to errors in diet, and the other non-naturals. (Sydenham, De Morbis Epidem. chap. 2. and Tractat. de Podagra.) From whatever source these cacochymias, or peccant humours originate, they are considered as inimical to the well-being of the body; in consequence of which enmity, nature, or the supposed precluding principle of the constitution (which has been variously perverted by different writers, under the titles of Arbores, Anteacutus, Animosa medicina, &c.) begins a contest, in order to expel from the blood this intruded peccant matter. "Reafon informs us," says Sydenham, "if I have any judgment, that a disease is nothing else than a struggle of nature, labouring with all her might to expel the morbid matter for the health of the patient." And, he remarks, in another place, "the inordinate commotion of the blood, which is the cause or concomitant of continued fever, is excited by nature, either for the purpose of separating some heterogeneous matter, contained in and offensive to it, or in order that the blood may be somehow or other altered in its diathesis." (Lec. cit. cap. 4.) Willis, Floyer, and others, view the subject in the same light, except that they introduce the firs as the agents employed by nature, for the purpose of exciting the commotion in the blood. "A fever," says Floyer, "is a preternatural fermentation or effervescence of the blood, occasioned by some ferment irritating the spirits of the blood and nerves, for the diffusing, or putrefying, and separating some part of the cacochymical fucus nutrion from its mixture with the mafs of humours. (P. 210.) According to the peculiar nature of the cacochymia, or morbid humour, the nature of the fever was supposed to vary. "It is evident that every person has some antecedent cacochymia," says the same writer, "by which the particular symptoms of the fever are produced, &c. The several stages of the disease are very naturally described by the separation of the greater or less quantity of the fucus nutrion from the blood, in the increafe of the fever, and the circe is a full or perfect separation of all the depraved fucus nutrion from the mafs of blood, when the fever is curable, and then the effeéтив effervescence ceases; but if the fucus nutrion be but in part separated, the mafs of humours remains turbid and underperated, and the fever becomes fatal." (Floyer, chap. 15. App. i. of Fevers.) When this morbid humour, Instead of being thrown out by the excretions, as in the case of critical diacharges by diarrhoea, turbid urine, or sweats, is vacuated
“evacuated upon particular parts, it produces the several inflammations; as quinsies, apoplexies, lethargies, pellisy, pleurisy, hematomata, cæles, which are the symptoms of the ordinary intermitting fever, and distinguish it into its several species.” Ibid.

But as acute, or febrile diseases, which terminate in a short time, (e.g. within the compass of fourteen or twenty-one days,) were considered as resulting from this active fermentation, and depuration of the humours; so, according to Sydenham, all chronic diseases, which run through a long and indefinite period, arise from an imperfect digestion or fermentation of the offending humours, and the consequent inability of nature to expel them. “For when any person has on the one hand, the principles of his nature debilitated or worn out, whether by old age, or by great and continual errors of the non-naturals, particularly in respect to food and drink; or, when, on the other hand, the organs of secretion have been so far weakened, as to be unable to separate the blood, by carrying off its excrementitious and superfluous parts; in these cases, a greater quantity of humours is accumulated than the powers of the individual are capable of digesting or concocting, which humours, in consequence of their detention, undergo various degrees of fermentation and putrefaction, until at length they assume specific properties, and, according to the variety of deprivation, give rise to various forms of disease. They also fall upon particular parts, which are more disposed to receive them according to their peculiar qualities; and thus ultimately produce the long trains of symptoms, which are designated by the names of certain diseases, and which vary in relation to the nature of the morbid humour, and to the morbid condition of the part, respectively.” Sydenham, Tractat. de Podagra.

It may be inferred, from the long and extensive prevalence of this humoral pathology, that it was not founded on mere fancy; but that something like found observation and established facts could be adduced in support of it: and we have already hinted, that the common occurrence of certain profuse or altered excretions, towards the termination of febrile diseases, was deemed conclusive evidence of the truth of the hypothesis. But the doctrine was apparently strengthened still more, where there occurred not a mere increase of the ordinary excretions, but the discharge of a new and preternatural humour, altogether uncongenial with the healthy blood. Thus, when a tumour formed in any particular part, from the suppurative settling of the peccant matter there, an inflammatory commotion or fermentation took place, in consequence of which, as the morbid matter became concocted, an abscess was formed, and the pus or febris, which was at length discharged from it, was deemed a proof of the existence of the morbid ferment. In this way the buboes, which occur in the plague,—the abscesses in the different glandular, membranous, and muscular parts,—the eruptions in the skin in small-pox, measles, &c.,—the formation of chalk-stones, after inflammatory gout,—and the expectoration of purulent and mucous phlegm, in consequence of inflammation in the lungs and bronchial passages,—all these phenomena were believed to be conclusive proofs of the correctness of the humoral theory. And a still stronger proof appeared to exist in the well-known fact, that in small-pox, the plague, &c., the matter thus discharged was as completely a ferment, when received into the healthy humours of another person, as barm or yeast, introduced into a cask of infusion of malt or grape-juice. But this was not all: a sort of ocular demonstration of the existence of a morbid humour in the circulating fluids appeared to be deduced from the condition of the blood, which was drawn from persons labouring under inflammatory diseases; and which, when it had cooled, exhibited a thick, tenacious fœt upon the surface of the coagulum, which has been called the lea or fœtyco Vegan of the blood, and is not found on blood taken away, when no fever is present. Some collateral evidence was likewise deduced from other phenomena of diseases, and especially from the occasional occurrence of what is termed a papuâ, or the sudden translation, as it were, of a disease from one part of the body to another. As this was most commonly observed to take place between an external and internal part (as the gout, for instance, disappearing on the foot was transferred to the stomach;—or when an eruption faded on the skin, and vomiting or diarrhœa succeeded in the alimentary canal); so it was concluded, that the efforts of nature to expel the morbid matter had either been too feeble, or had been counteracted by improper treatment, and that the matter had fallen back upon the internal organs, where it excited the new struggle of nature to get rid of it by another channel.

This hypothesis, however, which is founded upon a coarse and vulgar analogy between a merely chemical process, and the operations of the living body, could only remain plausible, so long as the nature both of chemical combinations and of the properties of the animal economy had been the subject of very limited investigation: upon a more accurate inquiry, we find the points of analogy do not exist. The various changes, which take place in the fluids of the living body, do not occur from mere chemical action, as in the case of fermentation of the elementary parts upon each other; but arise from some peculiar action of the vessels, through which they circulate. Thus, the vessels of the liver alone elaborate the blood into bile; those of the kidneys form the urine, and those of the testes produce the seminal liquor. No admixture of the parts of the blood, in any other situation, is capable of generating these peculiar humours. In a similar manner, the morbid humours are the result of certain ingrate and irregular action of the vessels of particular parts. Thus, when any organ is in a state of inflammation, which, in fact, consists in an undue dilution and activity of its vessels, the pus, or other matter, which is formed in consequence, is generated in the affected part, is the effect of the inflammatory action, and is not brought by the circulating blood, and deposited there, to be the cause of the inflammation. In small-pox, for example, or meases, the contagious matter is not found circulating with the mass of blood, but is generated by the action of the vesels of the febris, where alone it appears; if it contaminated the circulating mass, it would, doubtless, be deposited in the internal parts: but no phials were ever found in these diseased, in any of the viscosa or internal organs. No such change, as that occasioned by a ferment, therefore, takes place. This is farther proved by the fact, that by augmenting the action of the cutaneous vessels, on any particular part of the surface, (as by the application of heat, or any stimulating substance); on that particular portion, the quantity of phials, in small-pox, will be augmented, and vice versa. In a word, it appears that, as neither bile, urine, nor saliva, is found circulating in the blood, so neither is the matter of contagious diseases excited there; just as in the diabetes mellitus, when the kidneys are constantly throwing out large quantities of saccharine matter, no traces whatever of sugar, or its elements, can be detected by the chemist in the circulating blood.

On the other hand, the inference drawn from the fœt upon the coagulum of blood, drawn under the circumstances of fever, is incorrect. For that fœt is simply the fibrin or coagulable lymph, which con-
HUMORAL PATHOLOGY.

states a part of the blood under all circumstances, and which
shews itself apparently more or less according to the less or
greater rapidity of coagulation; which again is influenced
by the force or rapidity of the action of the reff from
which it flows, or by its manner of flowing; infomuch that
if the blood be received into different vessels, during the
same bleeding, the bloody coat will appear on some, and not
on the others. It may be likewise added, that many fevers
terminate in health, where no cribes or feeible discharge has
preceded recovery.

With regard to the argument deduced from the occur-
rence of materia medica, little can be inferred from it in support of
any position: the fact is very difficult of explanation by any
hypothesis. It is at least equally easy, and consistent with
our knowledge of the animal economy, to refer the transition of
morbid actio to the communication of certain internal
and external parts by nervous sympathy; as to conceive that
a morbid matter is mechanically transferred, through the me-
dian of the circulating mass of fluids, from one organ to an-
other. The existence of a morbid matter is hypothetical;
wheres the existence of a sympathetic connection, through the
medium of nerves, in a matter of observation and experiment;
whence the connection between the skin and the alimentary
canal may be mentioned as an example. If we excite naufea
or vomiting in the stomach, we induce a perspiration on the
skin; and by moistening the surface, we speedily relieve the
feint of thirst, &c. Besides, there is no proof of the
actual translation of the morbid matter, or the fame form of
disease in cases of materia medica; for, to instance gout, we do
cannot the chirry matter of the hands or feet appearing in the
stomach, when the disease is transferred to that organ,
but what is inflammation on the surface, is commonly epifura
in the stomach; and, on the principle of nervous sympathy,
the identity of the disease, thus excited in diffent parts, is
not a necessary supposition.

The arguments for the contrary doctrine, which refer the
phenomena of life, whether in a state of health or disease, to
the agency of the nervous energy or senforial power, re-2
dent in the living folsids, and to the various action of the
moving fibres, have been deduced from a long series of ob-
ervation and experiment. See LIPF, EXCITABILITY, &c.

The pernicious refults of the practice, however, to which
this humoral pathology led its advocates, afford an additional
repealment of its principles. The doctrine that
influnated all morbid actions, for the purpose of expelling from
the constitution certain offensive and dangerous matter, either
conducted, on the one hand, to function a very feeble and
inert practice, but the falutary operations of nature should
be impeded or deranged; or, on the other, to enforce a active
practice, by which it was intended to aid and cooperate
with nature in her suppozed two-fold endeavours, first to con-
cort or boldly ferment the morbid matter, which annoyed her,
and secondly, to expel it by the proper emunctories. Of
these two practical lytens, the first, or la medicina expellens,
as the French have emphatically called it, is, doubtless, the
leaf indifferent. It conformed in doing nothing, with the
appearance of doing something; and, therefore, obtained the
confidence of the patient, and tranquillized his mind,
which constitutes one step towards a cure. The remedies
conflicted of what have been termed demulcents, diuretics,
humectants, &c. or aqueous liquors, with various vegetable
mucilages, sugars, and flavors, all abundantly harmless in
their qualities, and certainly not interfering with any pro-
cesses of the constitution, whether falutary or deleterious.
But if this be the highest reach of the medical art, (which, indeed,
is rather the rejection of all art,) to what purpose have the

fludies of scientific men been directed, the structure and
functions of the human body been investigated, and a pecu-
lar class of mankind devoted to the practice of medicine?
La medicina expellens is purely the weakest of all empiri-

It has always been a popular doctrine, and it is one that
carries a great deal of plausibility in the face of it, that the
main object, and the sum total of the powers of medicine,
consists in aiding the natural efforts of the constitution for
the removal of diseases. But this proposition requires consider-
able qualification. If it be merely meant, that medicine
can only operate through the medium of the powers or en-
ergies of the living body, and that, independently of the
vital energies, medicine has no operation, the position is a
truism which cannot be questioned. But if it be meant,
that the sole power and object of the medical art are limited to
the furthering of all morbid excitement, and to the removal of
obstacles to the completion of the purposes of that excite-
mation; i.e. to affording the efforts of nature or guarding them
from interruptions, the assertion appears to be altogether
gratuitous, and nothing less than an abuse of language. In
the first place, it is founded on the assumption, that all dif-
cealed action is falutary, which the effects of numerous dis-
eases directly contradict, and which has no better founda-
tion than two other gratuitous assumptions, namely, the
existence of a morbid ferment in the blood, and of an archeus,
or rational soul, governing all the operations of the animal
body. But, secondly, admitting the falutary tendency of dif-
cealed actions, considered as the efforts of nature, by what
signs are we to interpret her intentions, or to discover when
she requires affilations, and when refrains? On this point the
greatest practical errors are likely to be committed, and have,
in fact, been constantly and extensively committed, by
those humoral pathologists, who have presided upon
their knowledge of the intentions of nature. Had they
been unsulled observers of nature's indications, they
would have attended, probably, to the fuggations of those
sentences and infeetive feelings in the sick, which are gen-
erally deemed sufficient directions to the healthy, and which
appear to be the universal guides to the physical conduct of
the whole animal creation. They would have allowed the
thirsty to drink, the hot to be cooled; and would have at-
tempts to relieve the various painful sensations, according to
the cravings which they suggested. But their practice
was commonly the very reverse of this; for they deduced
their inferences, not from these unequivocal guides, but from
their hypothetical conceptions of the proceedings of nature.
Their own proceedings, therefore, were directed to en-
courage the increase of the disease. Thus in all fevers, even in
those where there was considerable inflammatory affecti-
on the whole skin, (as in small-pox,) they accumulated the
heat of the patient, already almost intolerable, with a view
to perfect the fermentation or concoction, which they sup-
posed nature was labouring to accomplish; and hence they
rendered mild fevers fevers, and severe ones certainly fatal.
At the same time, they stimulated the action of the heart
and arteries, by cordial, volatile, and aromatic medicines,
and by heat conveyed internally in the drink, and thus still
further multiplied the evil. And it was particularly unfortu-
nate for the patient, and for medicine, that this augmentation of the
original disease, (as in the increase of the eruption in
small-pox, scarlet fever, &c.) and even the actual excitement
of new diseases, (as in the epidemic eruption over the skin, which
this heating practice frequently produced in all fevers,) were
conceived by these pretended interpreters of nature, to be no-
thing less than new and occult proofs of the truth of their dow-

Vol. XVIII.

HUMOROSI, the name of an academy established at Cortona in Italy.

The Humorosi of Cortona must not be confounded with the Humoristii of Rome.

HUMOUR, or HUMOR, in its general sense, signifies the same as liquor, or liquid.

HUMOUR, in Medicine, is applied to any fluid part of the animal body, as to the blood, bile, mucous, serum, saliva, &c. as well as to the pus, fumes, &c. which result from disease. The ancient physicians, and after them the moderns down to a late period, considered health and disease as arising from a due proportion or disproportion of four humours in the body: namely, of blood, phlegm, yellow bile, and black bile. (See GALEX.) This doctrine, respecting the origin and nature of diseases, as dependent altogether on the state of the humours of the body, has been denominated the Humoral Pathology; which see.

HUMOURS of the Eyes. Anatomists and opticians differ in the number of the parts of the eye (see EYE); which they call the aqueous, crystalline, and vitreous. These three humours have each their share in the refraction of the rays of light necessary to vision.

Authors, both ancient and modern, speak of the regeneration of the humours of the eye; and give us instances of their reproduction, when, by any accident, they had been let out; but their influences, strictly considered, generally go no farther than to the aqueous and vitreous humours.

Horrid only, in a letter to Bartholinus, says much of the crystalline. He affirms, that he has filled the pupil of the eye of divers animals, and squeezed out all the humours, even the crystalline, and has afterwards perfectly restored them again to fight; and that the eyes of the birds, whereon the operation had been performed, instead of being damaged thereby, were rendered more lively and vigorous than usual. He adds, that he had performed the same experiment on divers persons, with so much success, that there remained not the smallest appearance of a cataract in the eye. See CATARACT.

obviously founded in misapprehension: (see Boerhaave, Praxis Medica, vol. 1, p. 122 & seq.) and further, as Dr. Cullen remarks, it is not consistent with what Boerhaave himself has delivered elsewhere. (First Lines, pref. p. xxx.) The doctrine of a spontaneous gluten in the blood, incited by that celebrated author, (loc. cit. p. 145) is also gratuitous. Some proofs adduced for its existence are manifestly founded on a mistake with respect to what has been called the buffy coat, or inflammatory crust; and the many examples given by Boerhaave of a gluten appearing in the human body, are all of them nothing more than instances of collections or concretions, found out of the course of the circulation.

To conclude with the words of Dr. Cullen, although the fluids of the human body may undergo various changes, we must maintain that the nature of these changes is seldom understood, and more seldom till is it known when they have taken place; that the reafonings concerning them have been, for the most part, purely hypothetical; have therefore contributed nothing to improve, and have often misled, the practice of physic. In this, particularly, they have been hurtful, that they have withdrawn our attention from, and prevented our judging of, the moving powers of the animal system, upon the state of which the phenomena of diseases do more certainly and generally depend." First Lines, pref. p. xxxii.

It cannot be doubted, that one of the greatest improvements ever made in the medical art, is the discovery of the circumstances, under which a free application of cold may be made in febrile diseases, aided by the early use of purgatives, and the removal of every other species of irritation on the living fold, which confluence what has been called the antiphlogistic plan of treatment. For the establishment of this practice, in regard to the free use of cold, upon clear and philosophical grounds, we are principally indebted to the late Dr. Currie of Liverpool. So far from experiencing any injury or danger from not encouraging this practice, or from repelling the morbid matter, it is ascertained, by innumerable observations, that it is most salutary to reduce the temperature of the surface of the body, in the height of the eruptive fever of scarlatina, for instance, and that this otherwise formidable disease may be thus cut short in its duration, mitigated in its severity, and conducted mildly to a safe termination. (See Cold, as a remedy: also Heat, Fever, and Scarlet Fever.) In a word, it is now ascertained, that that practice, in febrile diseases, which is founded on the principle of removing or diminishing the excitement of the sensible and irritable folds, and thus of lessening the increased action of the vesicles, generally and locally, without any reference to a peccant state of the humours, is attended with a degree of success, not to be compared with that of the humoral pathologists; and that man is more correctly treated as a being polluted of senforial powers, than as a barrel of fermenting fluids.

It were unnecessary to enter into other practical absurdities of the humoralists, such as the frequent letting of blood, even in chronic diseases, upon the supposition that the morbid matter, which is believed to contaminate the whole circulating masses, should be all discharged with the small portion of this fluid, that escapes through the orifice made by the lancet, and leave the remaining masses thoroughly deparuted; — the use of purgatives on the same principle; — the interdiction of purgatives in the early stage of febrile diseases, because the peccant matter is supposed to be yet in a crude or uncorrected state; — and lastly, the numberless farrages of useles and inert herbs, mixed together upon some fanciful notion of their properties for correcting various modifications of cæcality, which they constantly prescribèd in chronic maladies; the qualities both of the bile and antidotc, the morbid humour and its corrector, being equally gratuitous and hypothetical.

We have said nothing on the subject of that humoral theory, which referred diseases to the two opposite conditions of the fluids, the acid and the alkaline cæchymia, upon which Boerhaave and some others reasoned with considerable ingenuity: for this doctrine was never generally received; and, except in so far as the contents of the stomatch and first palpiages exhibited a tendency to one or other of these qualities, according to the modifications of indigestion, it is
HUMOUR.

Humour is also used, in Dramatic Poetry, for a subordinate species of what the critics call manner.

Humour is usually looked on as peculiar to the English drama, at least our comic poets have excelled therein; and carried it beyond those of any other nation; and our is, perhaps, the only language that has a name for it. The nature of such a free government as our's; and that unrestrained liberty which our manners allow to every man of living entirely after his own taste, afforded full escape to the display of singularity of character, and to the indulgence of humour in all its forms. Hence comedy has a more ample field, and can flow with a much freer vein in Britain than in France, where a much greater uniformity has been spread, at least in former times, over the outward behaviour and characters of men, by the influence of a despotic court, subordination of ranks, and the rigid observance of the forms of polite ness and decorum. As to our English dramatists, who does not acknowledge the transcendent excellence of Shakespeare in the province of humour? Of the later comic writers, Congreve has an exuberance of wit, but Farquhar has more humour. It has been observed, however, with too much truth, that, to the discredit of our stage, as well as of the national delicacy and discernment, obliquity has too often in English comedy been made to supply the place of wit, and belittling the place of humour. It should be acknowledged at the same time, that a considerable reformation has taken place in this respect.

Humour is usually considered by critics as a fainter or weaker habitual passion peculiar to comic characters, as being chiefly found in persons of a lower degree than those proper for tragedy.

Every passion may be said to have two different faces; one that is serious, great, formidable, and solemn, which is for tragedy; and another that is low, ridiculous, and fit for comedy; which last is what we call its humour.

Wit only becomes few characters; it is a breach of character to make one half the perions in a modern, or indeed in any comedy, talk wittily and finely; at least at all times, and on all occasions. To entertain the audience, therefore, and keep the dramatic persons from going into the common, beaten, familiar ways and forms of speaking and thinking, recourse is had to something to supply the place of wit, and divert the audience from out of character, and this end is attained by humour; which therefore is to be looked on as the true wit and humour.

A very good judge, the duke of Buckingham, makes humour, to be all in all; wit, according to him, should never be used, but to add an agreeableness to some proper and just sentiment, which, without some such turn, might pass without its effect.

Humour, or continued wit, in Oratory, is a certain sprightly and vivacity of thought, which runs through a discourse, and shews itself in agreeable images, beautiful turns, and a facetious manner of expression, suited to the subject, and affecting the hearers with pleasure and delight, though not to that degree as to excite laughter, or any great emotion of the passions.

The nature and efficacy of humour are unravelled by Dr. Campbell, in his "Philosophy of Rhetoric." in the following manner. A just exhibition of any ardent or durable passion, excited by some adequate cause, instantly attacks sympathy, the common tie of human souls, and thereby communicates the passion to the breach of the hearer. But when the emotion is either not violent or not durable, and the motive not any thing real, but imaginary, or at least quite disproportionate to the effect; or when the passion displayed itself preposterously, so as rather to obstruct than to promote its aim; in these cases a natural representation, instead of fellow feeling, creates amusement, and universally awakens contempt. The portrait in the former case we call "pathetic," in the latter "humorous." The passion which humour addresses as its object is contempt; and the subject of humour is always character, but not every thing in character; its fables, generally, such as caprices, little extravagances, weak anxieties, jocundities, childish fondnesses, pettiness, vanity, and selfishness. In expressing passion as it appears in the more trivial occurrences of life, we commonly use this term, as when we talk of good humour, ill humour, peevish or pleasanl humour; hence it is that a censuring temper we call humourous, the person pallidifies of it a morose, and such facts or events as afford subject for the humorous, we denominate comical. Accordingly, the term humour is used to express any lively figures of such specialties in temper and conduct, as have neither moment enough to interest sympathy, nor incongruity enough to excite contempt. In this use humour, not being addressed to passion but to fancy, must be considered as a kind of moral painting, and differs from wit only in these two things; first, in that character above is the subject of the former, whereas all things whatever fall within the province of the latter; secondly, humour paints more sharply by direct imitation, wit more variously by illustration and imagery. Of this kind of humour, merely graphical, Addison hath given us numberless examples in many of the characters he hath so finely drawn, and little incidents he hath so pleasantly related in his Tattlers and Spectators. We might remark of the word humour, as well as of the term wit, that we scarcely find in other languages a word exactly corresponding. The Latin facetiae seems to come the nearest. Thus Cicero, "Hiue generi orationis apergerunt eiam, qui in decendo mirum quantum valent; quorum duc genus fuint, unum facetiarum, alterum dicacitatis; uterque utroque, sed altero in narrando aliquid venufet, altero in jactando minimo; ridicendo cujus gener prata furtam." Orator. 45. Here one would think, that the philosopher must have had in view the different provinces of wit and humour, calling the former dicacitas, and the latter facetiae; but nevertheless these two words are often confounded both by him and other Latin authors.

Mr. Pope, in the second Canto of his "Rape of the Lock," has furnished us with an instance of wit and humour combined, where they reciprocally fill off and enliven each other:

"Whether the nymph shall break Diana's law,
Or some frail China jar receive a fall,
Or stain her honour, or her new brocade;
Forget her prayers, or miss a majestade;
Or lose her heart, or necklace at a ball;
Or whether heaven has doomed that shock must fall.

This is humorous, as it is a lively sketch of the female estimate of niceties, as our poet's commentator rightly terms it, marked out by a few striking expressions. It is likewise witty, for not to mention the play on words like a trope familiar to this author, you have here a comparison of a woman's chastity to a piece of porcelain—her honour to a costly robe—her prayers to a fantastic chignon—her head to a trinket—and all these together to her hands, and that founded on one lucky circumstance, (a malicious critic would perhaps discern or imagine more,) by which these things, how unlike severer in other respects, may be compared.
pared, the impression they make on the mind of a fine lady. Hudsions abounds in all the varieties of wit, nor is his poem delictute of humour, exhibited in the characters of the knight and his squire, and more especially in the consulta-

tion of the lawyer, part iii. canto 3. But there is perhaps no book in any language, in which the humorous is carried to a higher pitch of perfection, than in the adventures of the celebrated knight of La Mancha.

Humour, says Dr. Campbell, when we consider the contrariety of its effects, contempt and laughter, (which con-
stitute what in one word is termed 
drastic,) to that sympathy and love, often produced by the pathetic, may in re-

spect of these be aptly compared to a concave mirror, when the object is placed beyond the focus; in which case it appears by reflection, both diminished and inverted, circumstances which happily adumbrate the contemptible and the ridiculous.

HUMBER, Crystalina, Digests, and Opacity of. See Ca-

taract.

HUMP, in Geology, is applied by Dr. Townon and others to express a hidden rising or hump in the terrestrial strata, in the likeness of calved ridges, horn-backs, &c. by practical miners. It seems probable, that many dem-

duced patches of strata, like the limetone of Care. (see that article,) in Derbyshire, Breedon, and Cloud’s-hill, in Lei-

cestershire, Dudley Castle, Wren’s-nest, and other adja-

cent hills in or near Staffordshire, &c. owe their origin to humps previously existing in the strata, thus locally exposed by the denuding or carrying off the thinner parts of the superfincubent strata, which covered these hidden lime stone hills.

HUMP, Naked, North-west, South, and South-east, in Geo-

graphy, small islands in the Mergui Archipelago, in N. lat. 10° 23'—10° 19'—10° 9', and to 12°, respectively.

HUMPH, in Mining, signifies, in some parts of Scot-

tland, a blind or foul sort of coal, of little value.

HUMPHREY, Pelham, in Biography, was brought up with Blow and Mich. Wife, in the Chapel Royal, under Capt. Cook, who was appointed master of the children at the Restoration. When Humphrey lost his tre-

ble voice, he was admitted in 1666 a gentleman of his ma-

gelty’s chapel, and on the death of Capt. Cook, 1673, was ap-

pointed master of the children. He did not, however, long fill this honourable situation, as he died, very much re-

graded, at the early age of twenty-seven, in 1674.

His choral compositions are numerous for so short a life; as, besides his seven full and verse anthems, printed by Dr. Boyce, there are five prefaced in care by Dr. Aldrich, in Chrift-church, Oxford; and six in Dr. Tubb’s collection, British Museum, that have never been printed.

As French music was much better known in England during the reign of king Charles II. than Italian, there are in the melody of this composer, and in that of Parcell, passages which frequently remind us of Lulli, whom king Charles pointed out to his musicians as a model. Indeed, it is said that Humphrey was sent to Paris by the king, in or-

der to study under Lulli; and that, besides his merit in com-

position, he was an excellent performer on the lute. Indeed, he seems to have been the first of our ecclesiastical componers who had the least idea of musical paths in the expresion of words, implying supplication or complaint.

His anthem for three voices, “Have Mercy upon me O God,” has great merit on the side of expression, for the time in which it was composed, as well as harmony, in which there are several combinations that seem new and boldly hazarded for the first time, at least in choral music.

In his verse anthems many new effects are produced by mod-

ulation and notes of pause and exprefion.

The favourite interval in the melody of this composer is the falfe 11th, and, if it be true, as related by Dr. Boyce, that Humphrye studed under Lulli at Paris, he probably ac-

quired his partiality for this interval there, as it has long been in great favour in the serious French opera.

It is somewhat remarkable, that all the seven-verse anthems which Dr. Boyce has collected in his collection, by this favourite compositor, should be in flat keys, most of them in C and F minois, which are much out of time on the organ by the usual temperament of that instrument; however, if well sung, these crude chords may add to the melancholy

call of the compositions.

HUMPHREYS, Laurence, was born at Newport Pagnell, Bucks, about the year 1577. He was educated partly at Cambridge, and partly at Oxford. In 1599 he was admitted to the degree of B.A. and was elected fellow of Magdalen college, Oxford. In the year 1653 he obtained the permission of his college to travel for improvement for a year, on condition that he should avoid heretical company and places. This licence furnished him with means of withdrawing from the reach of queen Mary’s persecution, and of purifying his religious enquiries in company with men whose opinions were congenial to his own. He therefore 

fled abroad till the death of the queen restored his return safe. Upon his arrival in England, he was restored to his fellowship, which had been taken from him for his disobe-

dience to the injunctions of the licence which had been granted him; in 1660 he was appointed the queen’s pro-

fessor of divinity at Oxford, and in the following year he was elected president of his college. He suffered a short impre-

iment for refusing to take the sacrament in a kneeling posture, and though he was soon set at liberty, yet he got no preference till he furnished those seruples which amounted to non-conformity. After this he was created dean of Gloucester, and in 1580 he was removed to the deanery of Winchester, which was the highest preferment to which he ever attained. He died in 1646. His writings are very numerous, among which the following may be noted:

“Epilolta de Graee litteris et Homeris Librario et Imita-

tione.”

“De Religionis conservatio et reformatione degne praisu Regum.”

“De ratione interpretandi Arciése.”

“Optimae fidei obediencie, ejusque antiqua Origenis:”

the Life of bishop Jewell, and sermons. Dr. Humphreys was a great and general scholar, an able linguist, and a deep divine.

HUMPHRIES, John, a young English musician of promifing abilities, and a good performer on the violin, published, before he was twenty years of age, six folos for that instrument, which manifested more genius than ex-

perience. However, they were well received by diletantini performers, from being natural and easy. His successes in that publication encouraged him to further attempts, and in the year 1728 he published, by subscription, twelve sonatas for two violins and a bafe, which had some originality and agreeable imitations of Corelli, that made them the delight of musical clubs and provincial concerts in our own memory.

Humphries died about the year 1730, and left in MS. twelve concertos on Corelli’s model, which were printed after his decease, by Cooke, music-seller, in New-breet, Covent Garden; but the more fanciful works of Vivandi, Alberti, Teifareni, and Albini, being in circulation, and
the more solid productions of Handsel and Gemisini having refined and made the practical work of poor Humphries followed: him down the stream of Oblivion, unnoticed by the inhabitants of Earth.

HUMPOLETZ, in Geography, a town of Bohemia, in the circumference of Czazlau; 8 miles S.W. of Tertisch-Brod.

HUMPPILA, a town of Sweden, in the province of Tavalland; 50 miles W. of Tavallus.

HUMUS, in Botany, the Hop. This name is derived by Linnaeus from humus, moist earth, such as the plant in question prefers; but however ingenious this explanation may be, it appears that Humulus originated by corruption from Hulmus, a barbarous Latin word, of one common origin with Umula, or Humul, under which appellations, or something like them, the hop is known amongst various nations of the north.—Linna. Gen. 522. Schreb. 689. Willd. Sp. Pl. v. 4 729. Mart. Mill. Dict, v. 2. Sm. Fl. Bot. 1897. Jaff. 494. Lamarck. Illust. t. 815. (Humulus; Gerin. t. 75.)—Clains and order, Dryetia, Pumulina, H. nat. Orb. Schreb. Linna. Urs. Juft. Gen. Cham. Cal. Lamiu. of five, oblong, concave, obtuse leaves. Cor. none. Stam. Filaments five, capillary, very short; anthers oblong, burrily on a pore by each side, at the summit.

Female, Cal. the scales of a cattkin, ovate, large, tubular at the base, each containing two flowers, and at length serrate, perforate. Cor. of one petal, small, obtuse, lateral, enfolding the germ of each flower on one side. Fily. German small, roundish, comphret; styles two, very short; stigma long, awl-shaped, downy. Peric. none, except the permanent scales and corolla. Seed one, roundish, with a spiral embryo.

Female, Calyx the scales of a cattkin, two-flowered. Corolla of one petal, lateral. Styles two. Seeds solitary, invected with the corolla.

1. H. Lupulus, the only species of this very natural and distinct genus, Linna. Sp. Pl. 1457. Engl. Bot. t. 427. Mill. Illust. t. 88. Bulliard. t. 234.—Native of hedges and bushy places in a moist deep soil, in various parts of Europe, as well as in North America, blooming in July. The roots are perennial, branching. Stems annual, twining, angular, rough, with deflexed prickles, leafy. Leaves opposite, entire, heart-shaped, undivided or three-lobed, often five-lobed, serrated, velvety and hard. Flowers small, strong, angular, prickly, Stipulae between the filaments, reflexed, ovate, entire, smooth. Flowers green; the scales panicked, numerous; females on a separate plant, in axillary, flaked, ovate, drooping cattkins, of an aromatic scent, and bitter mastic quality.

Humulus, in Gardening, comprises a well-known plant of the most hardy, twining, perennial kind; of which the species is the cultivated hop (H. lupulus).

There are plants of this kind which bear only male flowers, that grow in long clusters; and others which bear female flowers only, that are produced in roundish, seedy, and leafy clusters. The latter is the furst coiled and grown; and which is distinguished into the early white, the long white, the oval, and the square garlic hop.

The hop-plant is principally grown in gardens, for the ornament and variety which it affords by twisting round different kinds of support to a very considerable height.

Method of Culture.—The hop is a plant which is usually increased by planting portions of the fucners taken from the roots of the old flocks. They are commonly cut six or seven inches in height, each having three or four even buds to throw out shoots from. And such as are of proper height should constantly be selected for this purpose, removing from each set every part of the old vine, as well as every portion that is hollowed or decayed in any way. The fets may be planted out in the autumn in any open place where the ground is well prepared and in a mellow condition.

The hop may also be raised by laying down the young shoots in the summer season, taking off their tops at the time the work is performed. These soon strike root, and form fets for use in the ensuing spring. See Hop.

Hop clumps have a good effect in many cafes, in large gardens or pleasure grounds.

HUMUS, in Natural History, a term formerly used for the decayed vegetable and mineral mixtures, more commonly known by the name of virgin mould, and forming the superficial crust of the earth. Parkinson's Organic Remains, vol. i. p. 83.

HUN, in Geography, a town of Africa, in Fezzan; 20 miles N of Mouzoun.

HUNARY, two small islands near the W. coast of Hindooistan; 85 miles S. of Bombay. N. lat. 18° 47'. E. long. 72° 38'.

HUNAUD, FRANCIS JOSIAH, in Biography, an eminent anatomist and physician, was born at Chateau-Briant, in February 1701. His father was a physician, and practised at St. Malo. He studied first at Nantes, and afterwards at Angers and Paris, and received the degree of M. D. at Rheims in 1722. On his return to Paris he studied anatomy and surgery with great accuracy, being a celebrated teacher. Winflow and Du Verney, and was admitted into the Academy of Sciences in 1724. Having been honoured with the appointment of physician to the duke of Richlieu, he accompanied that nobleman in his embassy to the court of the emperor Charles VI. at Vienna, and on his return retained his entire confidence, and had apartments in his house.

On the death of Du Verney, in 1730, Hunaud was appointed his successor, as professor of anatomy in the king's garden, where he soon acquired a reputation little short of that of his predecessor, and found the spacious theatre overflowing with pupils. Having been admitted a member of the faculty of medicine of Paris, he practised his profession with great success, and attracted the notice of the court. He took a journey into Holland, where he became acquainted with the celebrated Boerhaave, with whom he ever afterwards maintained a friendly correspondence; and, in 1735, he visited London, where he was elected a member of the Royal Society, at one of the meetings of which he read some Reflections on the Operation for Fistula Lacrymalis," which were printed in the Transactions. He was cut off in the full vigour of life by a putrid fever, in December 1742, being in his forty-second year. The greater part of his writings consist of papers, which were published in various volumes of the memoirs of the Academy of Sciences, between the years 1729 and 1742 inclusive. Osteology was a favourite subject of his research, and some of the most curious of his observations relate to the formation and growth of the bones of the skull. He likewise traced with great accuracy the lymphatics of the lungs to the thoracic duct, and the progress of some of the nerves of the thoracic vescera. He published anonymously, in 1726, a critique in the form of a letter, on the book of Petit, relative to the dissection of the bones, which occasioned some controversy, and received the formal disapproval of the academy. Hunaud had collected a considerable anatomical museum, which was especially rich in preparations illustrative of.
of ophthalmology and the diseases of the bones, and which came into the possession of the academy after his death. Eloy Dict. Hist. Gen. Biog. HUNBERGS, in Geography, a town of Denmark, in North Jutland; 8 miles S.W. of Aalborg. HUNDERBUHL, a town of Traniylvania; 12 miles S. of Scheiburg.

HUNDRED, Centum, Cont. the number of ten times ten or the square of ten. The place of hundreds makes the third in order in the Arabic numeration.

We usually express the proportion of the profits made in the way of commerce, &c. by the hundred.

Hundred of Lands, a denomination of measure, in some places denoting 50, and in others 25 heaped bushels or bags of land.

Hundred, in denomination of weights, of books is 104 lb.

avoirdupois = .9285715 great cwt. (112) = .8684636 long cwt. (120.)

Hundred of Cods, at Abourn, in Derbyshire, &c. = 128 lb. 8 stone of 16 lb. = 1.142857 great cwt. = 1.06666 long cwt.

Hundred of Ling, Cod, &c. = 124 lb. = 1.107143 great cwt. = 1.03333 long cwt.

Hundred, Great, or Standard, avoirdupois = 112 lb. = 4 quarters = 7 stone (of 16 lb.) = 8 stone horseman's, (of 16 lb.) = 14 stone, London (8 lb.) = 14 clove = 16 clove (7 lb.) = 1792 ounces avoirdupois = 20.072 ares = 93333 long cwt. (120 lb.) = 103 lb. 21/2 oz. Dutch Scotch weight. This is the legal hundred-weight of the common-house in London, and all the southern parts of England.

Hundred, Long, or Northern, = 120 lb. = 8 stone (14 lb.) = 12 rations (10 lb.) = 1.0714286 great cwt. (112 lb.) This is the hundred-weight legalized on all or most of the canals and navigable rivers in the north of England, and of the midland counties; by their acts for collecting tolls, &c.

Hundred is also used as a measure to express a certain quantity or number of things. A hundred of salt at Amsterdam is fourteen tons.

Deal boards are sold at six score to the hundred, called the long hundred. Pales and laths are counted at five score to the hundred, if five feet long; and six score if three feet long.

Hundred Weights, or the great hundred. See Quental.

Hundred, Diminutia. See Centner.

Hundred, Hundredum, Centuria, is also a part or division of a shire or county. It was so called, according to some, because each hundred found a hundred fidejoffiers, or furnishes of the king's peace, or a hundred able men of war.

Others rather think it to have been so called, because originally composed of a hundred families. It is true, Brompton tells us, that a hundred contains centum villas; but then Giraldis Cambrensis writes, that the site of Man hath three hundred and forty-three villages. In both these places the word milli must be taken for a country family; for it cannot mean a village, because there are not above forty villages in that island.

So, where Lambard tells us, that a hundred is so called, a centum centum hominum, it must be understood of a hundred men who are heads and chief of so many families.

Hundreds were first ordained, or rather introduced, by king Alfred, the twenty-ninth king of the West Saxons: (2) Alfredus rex (says Lambard, verbo centuria) ubi cum Guthruno Danus secundus interat, prudentialium olim a Juthon. Mofii datum secutus concilium, Angliam primum in fratrius, centurias, et decursas partitum eft. Sattripam, hyre, a Scytian (quod partires significat) nominatus, centurium hundred, et decuriam tollendae fve tamen, fve fve dedicatus collegium, appellum. Efteria, unde fidem nominibus vel Cnodule vocantur, &c. See COUNTY and Tithing.

We have already said that the inlitation of hundreds was rather introduced than invented by Alfred. For they seem to have obtained in Denmark; and we find in France a regulation of this sort was made above 200 years before; so an foot by Clotharius and Childebert, with a view of obliging each district to answer for the robberies committed in its own division. These divisions were, in that country, as well military as civil; and each contained 100 freemen, who were subject to an officer called the centurion; a number of which centuriae were themselves subject to a superior officer called the count or comte. (Monteig. Sp. Laws. 30. 17.) And indeed something like this institution of hundreds may be traced back as far as the ancient Germans, from whom they are derived the Franks, who became masters of Gaul, and the Saxons who settled in England; for both the thing and the name, as a territorial subdivision, are used in various districts, from which afterwards the territory itself might probably receive its denomination. And many other legal names are well known to that monarchies.

"Centuriae, lingulis pagis fuit, idque ipsum inter fraces, centurant, et quod primo numerus fuit, jam nomen et honor erect." Tacitus de Mor. Germ. 6.

Such is the original of hundreds, which still retain the name, though the jurisdiction be devolved to the county-court; some few excepted, which have been by privilege annexed to the crown, or granted to some great subject, and so remain still in the nature of a franchise.

This has been ever since the flat 14 Edw. III. whereby these hundred courts, formerly farmed out by the sheriff to other men, were all, or most part, reduced to the county-court, and so remain at present: so that where we read now of hundred-courts, they are to be understood of several franchises, wherein the sheriff has nothing to do by his ordinary authority, except they of the hundred refuse to do their office. See Hundred Court.

If any homicide be committed, or dangerous wound given in the day-time, and the offender escape, the town shall be amerced. And if out of a town the hundred shall be amerced, (2 Hawk. 74.) The hundred shall also make good the damage in case of robbery (see Hide and Cry), cutting banks or stop-honds; burning houses, barns, outbuildings, loaves, cocks, mows, or stakes of corn, straw, hay, or wood; mines or pits of coal; destroying granaries or corn intended for exportation; destroying turnpikes or works of navigable rivers, &c. 1 Geo. I. cap. 5. 2 Geo. I. cap. 22. 29 Geo. II. cap. 36. 6 Geo. II. cap. 22. 10 Geo. II. cap. 32. 11 Geo. II. cap. 22. 22 Geo. II. cap. 46.

Hundred, or Hundredum, is sometimes also used for an immunity or privilege, whereby a man is quit of the hundred-penny, or custom, due to the hundred.

Hundred Legh, signifies the hundred court, from which all the officers of the king's forest were freed by the charter of Canons.

Hundred Suit, the payment of personal attendance, ordering suit and service at the hundred court.

HUNDREDS, or HUNDREDORS, Hundredarum, are men impanneled, or fit to be impanneled, of a jury, upon any controversy,
controversy, dwelling within the hundred where the land in question lies.

By the policy of the ancient law, the jury was to come from the neighbourhood of the vill or place where the cause of action was laid in the declaration; and therefore some of the jury were obliged to be returned from the hundred in which such vill lay; and if none were returned, the array might be challenged for defect of hundreds. This was supposed to qualify those who composed the jury for forming a proper judgment of the evidence adduced, as they were supposed to know beforehand the characters of the parties and witnesses. But this convenience was overbalanced by another very natural and almost unavoidable inconvenience; that juries coming out of the immediate neighbourhood, would be apt to intermix their prejudices and partialities in the trial of rights. This our law has been to be sensible of, that for a long time it has been re-instituting this practice; the number of necessary hundreds is the whole panel, which in the reign of Edward III. were constantly fixed, being in the time of Fortescue reduced to four. Afterwards, indeed, the statute 35 Hen. VIII. c. 6. restored the ancient number of juries, but that clause was soon virtually repealed by statute 27 Eliz. c. 6, which required only two. And Sir Edward Coke also (1 Inst. 157.) gives us such a variety of circumstances, whereby the courts permitted this necessary number to be evaded, that it appears they were heartily tired of it. At length by statute 4 & 5 Ann. c. 16. it was entirely abolished upon all civil actions except upon penal statutes; and upon those also, by the 24 Geo. II. c. 18. the jury being now only to enume de corpore contadiunt, from the body of the county at large, and not de vicinage, or from the particular neighbourhood. See Arrest and Challenge.

HUNDRED is also used for him who hath the jurisdiction of a hundred, and holds the hundred-court. See Hundred.

Sometimes it is also used for the bailiff of a hundred. See Bailiff.

HUNDREDS, in the construction of reeds for weavers, denote the number of divisions in any given length of the reed. A thorough knowledge of the adaptation of yarn of a proper degree of fineness to any given measure of reed constitutes one of the principal arts of the manufacturer of cloth, as upon this depends entirely the appearance, and in a great degree the durability of the cloth when finished. The art of performing this properly is known by the names of counting, listing, or fitting, which are used indiscriminately, and mean exactly the same thing. The reed consists of two parallel pieces of wood of any given length, as a yard, a yard and quarter, &c. The divisions of the yard being into halves, quarters, eighths and sixteenths, the breadth of a web is generally expressed by a vulgar fraction, as 4, 4, 1, 1, &c.; and the subdivisions by the eighths or sixteenths or minims, as they are usually called, as 1/2, 1/4, &c. or 1/32, 1/64, &c. In Scotland the splits of cane which pass between the longitudinal pieces or ribs of the reed are expressed by hundred porters or splits. The porter is 20 splits, or 1/6 of an hundred. In Lancashire, Cheshire, and the other manufacturing counties of England, the divisions of the reed are different. A comparative table of the differences by which they are reduced, to the same standard as nearly as is possible, that is to say, within one split or division by which the Scotch or English manufacturer may at one glance ascertain the relation which the other modes of counting reeds bear to his own, is annexed to this article. In counting reeds by the number of hundreds in a determinate length, which is common to the manufacturers of the continent, as well as to those of Scotland, different lengths are used for the standard of fineness. In that part of France situated around Combray, which is, or was, the principal seat of the cambric manufacture, the standard length of a reed, by which the fineness of the splits is ascertained, is 34 inches. In Holland, where the heavier fabrics of linen are chiefly produced, the standard of measure is 40 inches; and in Scotland the standard is 37 inches, or the Scotch ell. Now it is plain, that if 2000 or twenty hundred divisions or splits be contained in each of these respective measures, those which are contained in 34 inches must be finer and closer than those contained in 37, and still more so than those contained in 40. For the practical purposes of manufacture in this country it can be of little importance to ascertain with precision the relative proportions which these standards bear to each other, but to the wholesale purchaser it must be useful to have some correct idea of the mode by which both the value and quality of the commodity which he purchases may be ascertained with considerable precision merely by inspection.

In Lancashire and Cheshire a different mode is adopted both as to the measure and divisions of the reed. The Manchester and Bolton reeds are counted by the number of splits, or, as they are there called, dents contained in 241/2 inches of the reed. These dents, instead of being arranged in hundreds, porters, and splits, as in Scotland, are calculated by what is there termed bars or bars, each containing 20 dents, or the same number as the porter in the Scotch reeds. Formerly the number of dents in a bar was frequently 19, a number ill ill calculated for any easy arithmetic calculation, that it is difficult to conjecture the canes which could have suggested its adoption, unless we suppose that the number 19, in place of 20, which was adopted to leave room for the shrinking-in breadth when first immersed in any liquor, to which all newly woven cloth is liable. The Cheshire or Stockport reeds again receive their designation from the number of ends or threads contained in one inch, two ends being allowed for every dent, that being the almost universal number in every species and description of plain cloth, according to the modern practice of weaving, and also for a great proportion of the fanciful articles. The number of threads in the warp of a web is generally ascertained with considerable precision by means of the small magnifying glass fitted into a socket of brass, under which is drilled a small round hole in the bottom plate of the standard, the number of threads visible in this perforation ascertaining the number of threads in the standard measure of the reed. These used in Scotland have sometimes four perforations over any one of which the glass may be shifted. The first perforation is 1/2 inch in diameter, and is therefore well adapted to the Stockport mode of counting, that is to say, for ascertaining the number of ends or threads per inch. The second is adapted for the Holland reed, being 1/4, 1/4, 1/4, &c. of 1 inch, and is therefore well adapted to the Stockport mode of counting, that is to say, for ascertaining the number of ends or threads per inch. The third is 1/4, 1/4, 1/4, 1/4 of 1 inch, and is adapted for the new almost universal construction of Scotch reeds, and the fourth, being 1/4, 1/4 of 34 inches, is intended for the French cambrics.

Every thread appearing in these respective measures, of course, represents 250 threads or 100 splits in the standard breadth, and thus the quality of the fabric may be ascertained with considerable precision, even after the cloth has undergone repeated wettings, either at the bleaching ground or dye work. By counting the other way, the proportion which the wool bears to the warp is also known, and this forms the chief use of the glass to the manufacturer and operative weaver, both of whom are previously acquainted with the exact measure of the reed.
Comparative Table of 37-inch reeds, being the standard used throughout Europe, for linens, with the Lancashire and Cheshire reeds, and the foreign reeds used for Holland and Cambric.

</table>

In the above table the 37-inch reed is placed first. It is called Scotch, not because it either originated, or is exclusively used, in that country. It is the general linen reed of all Europe, but in Scotland it has also been adopted as the regulator of her cotton manufactures. In the table it is only compared with the nearest English reed actually in use, for in most cases there is some small difference, which, however, is not material for practical purposes. For the Holland and Cambric reeds, the exact number of spindles is given merely for comparison, as these reeds are not at all used in Britain.

The art of proportioning the yarn to the reeds, for different fabrics, has always been regulated by the practical experience of the manufacturer, and the taste or fancy of his customers. Some attempts have been made to reduce it to a standard, and it is evidently a matter of no difficulty. Without analysing particularly the plans which have been proposed, and the arguments for and against each of them, it seems that the following may, in general, be taken as a good approximation.

Every species of yarn used in the manufacture of cloth, may be assumed to be a cylindrical body of fluid of a certain diameter. Now as the area of every circle is as the square of its diameter, and as the cubic content of every cylinder is found by multiplying the area of its base by its height, we may reasonably infer, that if the diameter of a thread is squared, and that square multiplied by its length, it will give the solid content, and vice versa; that the square root of the number which ascertains the weight of yarn, is a symbol of its diameter. If this be granted, it follows, that when any particular denomination of yarn is found to produce a proper fabric of cloth when woven in a reed of any given dimension, the proper denomination for any other reed may be found. Or if the yarn is at hand, and the proper reed wanted, it may be found by exactly the converse of the former analogy. Upon this hypothesis the analogy will be

As the square root of the given yarn, is to the given dimensions of the reed; so is the square root of another kind, to the dimensions of the reed required.

But as few practical manufacturers or weavers are accustomed to the extraction of roots, the real description of the yarn may be taken, and the reed squared, or multiplied into itself, which will give exactly the same result. It may be necessary to observe, however, in this place, that as the fineness of cotton yarn is ascertained by progressive numbers; and that of most other kinds of yarn, by the weight of certain quantities the proportion or analogy in the former case must be direct, and in the latter inverse, because a diminution of weight in a given quantity necessarily implies an increase of fineness. The two following examples will, it is hoped, render this sufficiently obvious.

If a manufacturer finds, by experience, that a fabric of goods, such as pleats his customers, is produced by weaving N 60 of cotton yarn in a reed of 1200 by the linen or Scotch reed, and wishes to ascertain what description of yarn he ought to employ for a web to be woven in a 1700 reed; the proportion will be

As 144, the square of the 1200 reed, is to 60, the number of the given yarn, so is 225, the square of the 1700 reed, to 94, the nearest integral number by calculation.

In the converse he would find the square of the reed, and would still find extraction of the root necessary.

But if a manufacturer of linen finds that a fabric of yarn, of any number of ounces to the spindles, is well adapted to a 1200 reed, and wishes to ascertain the weight or denomination of yarn fit for a 1700 reed as before, his proportion must be inverted.

The chief objection which practical men are apt to make to the above theory of adaptation, which is perhaps the bell that has hitherto been found, is the following. That in finer fabrics of goods it is not found to produce the desired effect, and that experience proves, that were a practical manufacturer of cloth to adopt this rule implicitly, either his fine goods would be wanting in that flow and elegance which is their chief recommendation, or that his coarse articles would be stiff and deficient both in warmth and durability. Allowing to this objection, which is unquestionably well founded, in some respects, all the weight which it deserves, the answer to it is very easy. The chief recommendations of coarse goods are thickness and strength, those of fine goods lightness and elegance. These are not, nor can be regulated by any exact mathematical rule, as they are much dependant on fancy. No lady would expect, in a fine dress, the strength and durability of a sack; nor would any tailor desire his flour in a bag, polishing the principal requisites of a sieve. It is sufficient, if the manufacturer is enabled to obtain a fair proportion for the real fabric, and this he must afterwards vary, to suit his goods to the market for which they are intended.

HUNDSHUBEL, in Geography, a town of Saxony, in the territory of Erzgebirge; 23 miles S.S.W. of Chemnitz.

HUNDSMARCK, a town of the duchy of Silesia, on the Nieder; 14 miles W.S.W. of Jadenburg.

HUNSDRUCK, a district of Germany, between the Rhine, the Moselle, and the Nahe; now a part of France.

HUNE, a bay on the S. coast of Newfoundland; 50 miles E. of Cape Ray.

HUNEFD, a town of Germany, in the bishopric of Pufia; eight miles N.E. of Pulda.

HUNERWASSER, a town of Bohemia, in the circle of Bohlen; 30 miles N. of Jung-Buntzel.

HUNG-TAR, a term applied in some districts to a straw.
A pipe EFG lets the water down from the spring in the hill, into a close-air-tight vessel H that stands at the foot of the hill, and contains 57½ cubic feet, or 330 gallons in wine measure. In this pipe is a clock, which, when opened or shut, lets the water of the spring run into H, or stops it, as occasion requires; and in H are two cocks b and c, the uppermost of which is for letting air into H, and the lowermost for letting the water out of it.

A small pipe I goes from the vessel H on the surface of the ground to a vessel K, in the bottom of the mine, and terminates in the top thereof. The vessel K in this case is also air-tight, and contains 27½ cubic feet, or 223 gallons in wine measure, which is forced up the ascending pipe LM, and runs off to w, at N, above ground. The lower end of this pipe goes down so far into the vessel K, as almost to touch its bottom.

From this vessel, a pipe O goes to the spring D under ground, which lets water into the mine, and would overflow it if the water was not forced up or raised from the mine through the pipe LM. The pipe O lets this water into the vessel K when the cock d is turned open, and keeps back the water when the cock is shut.

The operation is as follows: the cock b being open, and the cocks a and c shut, and no water in the vessel K, open the cock d to let the vessel K fill with water from the spring in the mine. As this vessel fills, the water will drive the air out of it, up through the small pipe I into the vessel H, and all that air will go out of the vessel H by the open cock b, and then H will remain, as it was before, full of air in the same state of density as the common air is on the outside of the hill. When K is full of water, shut the cocks b and d, and open the cock a, to let water run down from the spring in the hill by the pipe E F, into the vessel H. As the water rises in that vessel, the air will thereby be driven out of it, down through the pipe I, into the vessel K; and as this air is compressed by the weight of the running water in the pipe E F, the compressed air will force all the water out of the vessel K, up through the pipe LM, from which it will run off at N on the surface of the ground; and then the compressed air will rush out, after the water.

When the vessel K in the mine is emptied of water, and the air is heard to begin to rush out, shut the cock a to stop the water from the spring, and open the cocks b and c; then the water that came from the spring will run out of the vessel H by the cock c, and air will go in by the cock b; at the same time, open the cock d in the mine to let the vessel K fill with water from D the spring in the mine; and as H empties above-ground, K will fill below it; and the air that remained in K will (by the rising of the water in it) be driven back into the vessel H through the pipe I.

When H is empty of water, and K full, shut the cocks b, c, and d, and open the cock a; then H will fill with water from the spring in the hill; and this water, as it rises in H, will force the air out of H, down the pipe I, upon the water in K; and the force of the compressed air will drive all the water out of K, up the pipe LM, from which it will rush out at N, as before.

And thus, wherever there is a spring in a hill, near a mine that affords more water than what flows into the mine from a spring under-ground; and the perpendicular height of the spring in the hill is greater than the depth of the mine, water may be thus raised from the mine, in a most simple and easy manner by an engine in which there are neither pumps, pilions, nor valves: and such an engine will not be liable to be out of order, nor need repairs in many years.

But as there are very few mines that have hills near them with high springs, water cannot be thus raised from them in this manner; and therefore Mr. Blakey proposed another method, which was, to make an air-veessel, with a pipe going from it to another vessel in which is water, kept boiling by a fire under it, and this vessel to have a cock to let out the steam occasionally that rises from the surface of the boiling water. When the cock is shut, the steam will go off from the boiler into the air-veessel, and drive the air out of it, down through the pipe I into the vessel K in the mine: and the force of the air compressed by the elasticity of the steam, will raise the water from K, up through the pipe LM, till K be emptied of water. Then the cock in the boiler is to be turned open, to let out the steam, and the cock d to be opened to let the vessel K fill from the spring in the mine; and when it is full, both these cocks are to be shut, and the operation will go on as before.

That Blakey’s scheme would do, the Hungarian machine puts beyond all doubt. In both of them the vessels must be made very strong, because every part of each vessel, equal in surface to the bore of the ascending pipe LM, will sustain an outward pressure equal to the whole weight of water in that pipe. It will not answer for such depths as the common fire-engine will, nor will it raise so much water; but it may be built for less than a third part of the expense, and would answer very well where the depth is not above a hundred feet.

Hungarian Music. There is no doubt (says Mr. Laborde) but that the Hungarians, in abandoning Asia, about the ninth century, in order to inhabit Europe, made use of Asiatic musical instruments during their first year’s residence there.

These were almost all wind-instruments; of which their names, till full retain their Hungarian appellations, and are of that kind, is a proof. As the trumpet, batmà, is called kurt in the Hungarian dialect, and the flute, flù, &c. Other instruments have names, derived from other languages, as kislalmon Bognaris, organum, trombita tuba. All these words are of Greek, Latin, or German extraction, whence we conclude that the Hungarians, in quitting Asia, had only wind-instruments. If they had had others, they would have had words to express them. We see likewise that the pipe, the bow, arrow, and fable, are the only arms of which the names are Hungarian, as these were the only arms which this people knew when they arrived in Europe; their other military weapons are expressed by foreign words.

Hungarian music remained in its primitive state of mediocrity till the reign of Corvius, who was proclaimed king of Hungary at the age of 15, in 1458, and afterwards conquered the kingdom of Bohemia, and died at 47, in 1490.

This prince rendered Hungary equal to other countries in arts and sciences, by his patronage and by cultivating them himself. The pope’s nuncio, who came to Buda in 1483,
to make peace between the emperor Frederic and Corvinus, in a letter to his holines, says, "the fingers of this prince's chapel are the bell of all those I have ever heard."

Music was cultivated with the same ease under king Ladislaus VI. and Lewis II., but not with the same pomp, the number of the musicians of the household was considerably diminished. It appears likewise by the flate of music which is still preferred, that wind instruments have the precedence over all others.

The Hungarians, like all people not quite civilized, had tunes without time or key, to which they sung their coarse national ballads without harmony; however, though almost all uncultivated people love high tones and noisy music of a light and vulgar cast, the Hungarians preferred soft sounds and slow measures; which has rendered their music more of the feminine than the masculine gender. And we still see among the peasants who prefer their primitive manners longer than the higher orders of the people, that the girls assemble on great festivals, and sing in chorus odes and ancient poetry, which is never done by boys. Men, however, cultivated music; but it was only to celebrate the proverbs of their ancestors in patriotic songs. It is related that in a repall given by Attila, the Euchelius, or director of the music, had a feast on the right hand of the throne; and that after the service two men sung verses composed in honour of Attila's victories. Part of the audience wept, and, adds the historian, the rest grew furious and desired to be led to battle. Two stanzas of these songs have been preferred in their original language, and in Latin, to the following purport.

"Let us ever remember those ancient domains,

Which our ancestors left when they flew

To a climate more mild, from the Scythian plains,

Where dread mountains of snow are in view.

"To Hung'ry they hasten'd, with God for their guide,

And chose Transylvania for home;

Be their force and their courage for ever our pride,

But, like them, let us never again roam."

The knowledge of music was introduced into Hungary by the Christian religion and belles lettres.

As to the time when music was first in use at court, there appears, in a diploma granted by king Bela III. in 1193, that a pawn was sent to Paris of the name of Elvin, to learn the French melody.

It likewise appears in the Journals of the kings of Hungary, that the Hungarians, who came from Asia into Europe, brought to their new habitations the Asiatic manners, airs, dances, and songs; but that in process of time they cultivated the music and dancing of the neighbouring nations of Europe, till at length these two arts, practised by the sovereigns themselves, were held in great favour throughout the kingdom of Hungary. Effais for la Muses.

HUNGRARICA BOLUS, in the Materia Medica, a medicinal earth, commonly known by the name bolus Tocaccienis.

HUNGARICUS Morbus, or Febris Hungarica, the Hungarian disease, an epidemic and fatal fever, which originated in the camp of the emperor Maximilian II. in Hungary, in the year 1566, and spread through the greater part of Europe, causing every where a terrorized mortality, and almost depopulating Vienna, where the returning army halted in order to recruit. In some instances it seems to have put on the form of a remittent fever; but in general was a fever and malignant typhus, resembling the hospital or goal fever. (See Fever and Typhus.) Consult Sennert. lib. iv. cap. 14. De Morbo Hungarico. Ruland. De Lue Hungarica:

HUNGARY, in History and Geography, a country of Europe, formerly regarded as an independent kingdom, is bounded on the north by Poland, from which it is separated by the Carpathian mountains, on the east by Transylvania and Wallachia, on the south by Sclevonia, and on the west by Moravia, Austria, and Styria. Many authors comprehend under the general name of Hungary, Sclevonia, Dalmatia, Bosnia, Servia, Transylvania, Moldavia, and Wallachia. The ancient inhabitants of the western parts of Hungary were Pannonians, those of the northern Yazyggians. The Romans reduced Pannonia, and kept it almost 400 years, till they were driven out by the Vandals, who held it till the year 395, when the Goths took possession of their settlements, who, in their turn, yielded to the Huns. In the year 888, the Hun, under the name of Hungarians, made another irruption into Pannonia, against the Bulgarians and Sclevonians, whom they reduced. They had seven commanders, and Germany and many parts of Italy felt the effects of their savage ferocity. By degrees they became more civilized, and in the 10th century their prince Geard was made Christian by the pope. From that time Hungary was the first king of Hungary, and he completed the establishment of the Christian religion about the year 1000. He erected bishoprics, abbots, and churches; annexed Transylvania as a province to Hungary, and at his death he was canonized. After him followed a succeffion of kings, natives of the country, of whom may be mentioned Andrew II. who conferred great privileges on the nobility, and even empowered them to oppose the king if he should attempt any thing hostile to the laws of the country. In 1342 Louis I., furnamed the Great, subdued a part of Dalmatia, and carried his arms into Italy. He was succeeded by his daughter Mary, who was styled King of Hungary. She died in 1352, and the succession, which was some time controverted, at length terminated in the election of Sigismund, marquis of Brandenburg, who, in 1411, was chosen emperor of Germany. Albert of Austria, having married Elizabeth the heiress of Sigismund, was, with her, crowned king and queen of Hungary in 1458, an event which is said to form the earlist basis of the Austrian claim to the Hungarian monarchy. Upon the death of Albert, Ladislaus, king of Poland, was chosen king of Hungary, but perished in the battle of Werna against the Turks. The celebrated John Huniades was appointed regent of the kingdom. In 1458 Matthias Corvinus, son of Huniades, was proclaimed king of Hungary by the states, and in 1485 he feized Vienna, and the other Austrian states, and retained them till his death in 1490. Matthias was the most renowned prince that ever sat on the Hungarian throne: he was the friend and patron of letters, and founded a magnificent library at Eucha, and furnished it with the best Greek and Latin books, and many valuable manuscripts. After repeated contests, the house of Austria again filled the throne of Hungary, in the person of Ferdinand, 1527, but towards the end of his reign the Turks feized the greater part of this kingdom. On his being chosen emperor of Germany, Ferdinand retained the crown of Hungary till 1523, when he resigned it to Maximilian his son; and it has since continued a constant appanage of the house of Austria. The grand duchy of Transylvania was considered as a part of Hungary till the year 1540, when it began to be regarded as a distinct state. Stephen Batiotti was elected prince of Transylvania in 1571, and his family held the sovereignty till 1662, after which it continued subject to several elective princes, of whom the most distinguished was Bethlen Gabor, a noble Hungarian and Calvinist, who conquered great part
of Hungary in 1610, and died in 1629. The last prince of Transylvania was Michael Abaffi, who gave up the sovereignty to the emperor in 1694, since which period this country has formed a part of the Austrian dominions. In the year 1722, in the diet of Preßburg, the hereditary succession of Hungary was secured to the house of Austria, and in case of failure of male issue, it was enacted that females should be capable of holding the crown. Such are the historical epochs of this country. With respect to its surface, it is mountainous and barren towards the north; the air is cold but healthy. Towards the Danube the soil is level and sandy, and the climate very temperate. In the south the marshes are hot, moist, and unwholesome. Hot days, with cold nights, and habitual intemperance, occasion difficulties, particularly what is called the Hungarian fever. The level country bears abundance of corn, excellent fruit, and almost all kinds of vegetables. The forests are beautiful, and the meadows feed numerous herds of cattle. The fides of the mountains are covered with vines, and in their bowels are found all kinds of metals and mineral substances. The chief mountains are the Carpathian or Cracap: the principal rivers are the Danube and Drave. The Hungarians and Sclavonians are regarded as the only native inhabitants, though the Croats, Ruffians, Walachians, Vandals, Greeks, Jews, and Turks, likewise abound. Protestants are more numerous than Roman Catholics. Hungary is governed by the king and states: the latter are divided into four classes; to the first belong the prelates and other high orders of the church; to the second class belong the great barons, bans, or viceroys; to the third class belong the gentry, and to the fourth the royal free cities. Upon every view of the subject there appears to be between seven and eight millions of inhabitants, which are about one-third of the population of the Austrian dominions, and it yields about one-fifth of the whole revenue. The annual exports are equal in value to 1,600,000 florins, and its imports to little more than a million. The flandering military force amounts to nearly ninety thousand men. Preßburg is the capital. The Hungarians are tinctured with the manners of the Germans, but they remain a spirited people, and affect to defend their masters. The nobility are numerous, well informed, and warlike. Their lands owe their sovereignty no service. The peasant possesses nothing; he can be nothing but a farmer, and the proprietor can dismiss him at his pleasure. Anciently the peasants might change their masters; they cannot do so now: they have particular tribunals to which they might have recourse, but this privilege is no longer allowed. The Hungarian dress is well known to be peculiar, and is copied by our huskars. This dress, consisting of a tight vest, mantle, and furred cap, is graceful; and the whiskers add a military ferocity to the appearance. The languages spoken are numerous and different; they belong chiefly to three grand divisions: the Gothic or German; the Sclavonic; and lastly, the Hungarian proper, which has been confiscated as a branch of the Finnic.

HUNGARY-TOWN, a small-town in America, in Lunenburgh county, Virginia; 215 miles from London.

HUNGARY-WATER, AQUA HUNGARICA, a distilled water, so denounced from a queen of Hungary, for whose use it was first prepared, and who was cured by the continued use of it, of a paralytic disorder.

Hungary-water is one of the distilled waters of the shops; and is directed in the college dispensatory, to be made of rosemary flowers infused some days in rectified spirit of wine, and the spirit then distilled. The college of Edinburgh directs a gallon of rectified spirit to be drawn over in the heat of a water-bath from two pounds of the flowers as soon as they are gathered; that of London takes the tops and a spirit not quite so strong; putting a gallon of proof spirit to a pound and a half of the fresh tops, and drawing off in the heat of a water-bath five pints.

It is an agreeable perfume, and its virtues are much the same as those of the simple it is drawn from. The Hungarian water brought from Hungary is more fragrant than such as is generally prepared among us.

HÜNGEN, in Geography, a town of Germany, in the circle of the Upper Rhine, and county of Solms-Braunfelds; 14 miles S.E. of Wetzlar.

HUNGER, FAMES, a natural appetite or desire for food. For the symptoms, proximate cause, &c. of hunger, see Digestion. See also Abstinence, Bulimy, Diet, &c.

Hunger, in Biography, in 1772 organist of the Duomo, or Frauen-Kirche, at Dresden, of which church the organ was built by Silberman, and is regarded as one of the largest and most complete in Germany. The longest pipe in the pedals is 32 feet, and there are 48 flaps.

Though M. Hunger polished neither great fancy nor finger, his performance was truly masterly, and manifested a perfect knowledge of his instrument.

Hunger Creek, in Geography, a stream which supplies the water-machinery in the new and thriving manufacturing town of Hamilton, between Albany and Schenectady.

Hunger Rot, the name of a morbid affection in sheep, which is commonly produced by poor flinted keep, especially in the winter season. It is known with facility by the peculiar appearance of the sheep, which becomes extremely thin, lean, ragged, and emaciated. The principal means of restoring such animals, are those of changing them to drier pastures, and the gradual introduction of them into flocks of richer and better kinds. See Rot.

It is sometimes termed the hunger, or hungry evil.

HUNGERFORD, in Geography, is a market-town and parish, situated principally in the hundred of Kintbury, in the county of Berks, England, though a considerable part of the parish is in the hundred of Kinswardine, in the adjoining county of Wilts. The town stands on the banks of the river Kennet, near the road from London to Bath. Its ancient name, according to Camden, was Ingleford-Charnam-street; which Gough supposes to be a corruption from the ford of the Angles on Herman-street; a Roman road that crosses the town, the name of which appears to be yet preferred in one of its avenues, called Charman-street. The name of Hungerford, as now spelt, occurs in a record of the year 1204. At some distance west of the town is the church, an ancient structure, which appears to have been erected at different periods. It contains some old monumental memorials to the family of Hungerford, who derived their name and origin from this town. The civil government of Hungerford is vested in a constable, who is a citizen in the execution of his office by twelve footmen and burgesses, a bailiff, steward, town-clerk, &c. The market, which is on Wednesdays, has been held from time immemorial; it is mentioned as an established market in a record dated 1297. The market-house and smallows, which were erected in 1787, are roomy and commodious. Over the latter is a large room, used as a town-hall, for the dispatch of public business. In this room is deposited a curious reliquary of antiquity, denominated the Hungerford-horn, given, with an extensive right of fishery, by John of Gaunt to the inhabitants of the town. Here are three annual fairs. The town, by means of its canal navigation, has a considerable traffic; but no established manufactures. Hungerford is 64 miles from London; in the year 1801 it contained 494 houses, and 2202 inhabitants. At a short distance S.E. of the town is
HUNGERFORD, a town of Upper Canada, in the county of Hastings, lying in the rear and N. of the Mohawk tract.

—Also, a township in Franklin county, Vermont, containing, in 1790, 40 inhabitants; 7 miles S. of the Canada line, and 14. E. of lake Champlain.

HUNGRY EYRE, a term used among the farriers for the same distemper in horses, as in men we call a canine appetite. It manifests itself sufficiently in an inordinate desire to eat, and is sometimes the effect of long starving, sometimes of cold, or some other internal or external cause. In the latter case the horse not only eats a large quantity, but he devours it in a very remarkable manner, stopping it up, as if he would eat the very manger. The method of cure is to give him large toasts of bread, steeped in fack, or some other sweet wine; or give him a quantity of wheat flour in wine, or in milk, a quart or more at a time. These are very good remedies in case of emaciation, but otherwise he may be cured by feeding him moderately with bean-bread several times a-day, allowing no other food.

HUNGER HILL, in Geography, a high mountain in the county of Cork, Ireland, on the north side of Bantry bay, which is a remarkable landmark, and on which some alpine plants have been found, as falkus herbaceae, empenrum nigrum, &c. A fine cataract falls from it, especially after heavy rain.

HUNTER POINT, a cape on the E. coast of the island of St. Vincent. N. lat. 13° 28'. W. long. 61° 11'.

HUNTINGTOWN, a town of Meckly; 35 miles S.E. of Munnyjour.

HUNINGUE, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Altkirch, situated on the Rhine; 14 miles E. of Altkirch. The place contains 7742; and the canton 13,680 inhabitants, on a territory of 140,000 kilometres, in 23 communes.

HUNNARYD, a town of Sweden, in the province of Smaland; 18 miles S.W. of Jokioiproc.

HUNNEINE, a town of Algiers, near the coast; 10 miles N.N.W. of Taekumbrect.

HUNNERIC, in Biography, king of the Vandals, in Africa, succeeded his father Genseric in 477. He was a Venetian Arias, and though he at first gave his opponents toleration, he afterwards commenced a persecution against them, which, for savage barbarity, is said to have exceeded the perfecutions under the heathen emperors. He died in 484.

HUNNIADES, John Corvin, one of the most formidable captains of his age, who contended with and defeated the Turks in 1422 before Belgrade and in Transylvania. When the peace which succeeded was violated by the Hungarians, Hinniades accompanied Uladislus to the battle of Varina in 1444, in which the Christian army was entirely defeated, with the death of the King. Hinniades drew off the remainder of the forces, and by his vigour put himself in a condition to act offensively with success against the Turks. He was declared governor of Hungary for the minor king Ladislaus, then educating at the court of the emperor Frederic, who refused to give him up to the ambassadors of the nation. For a considerable time he was a terror to the Turks, but was at length defeated by them in 1448. In 1456 he compelled Mahomet II. to raise the siege of Belgrade. At this time Ladislaus, who had been restored to his subjects, fled in alarm to Vienna, and the hostile torrent would have been irresistible, had not Hinniades, after de-

feating a Turkish fleet on the Danube, thrown himself into Belgrade. Captivating a monk, by his success in converting the clergy, he was instrumental in bringing him large reinforcements; by the aid of which Mahomet was repulsed with great slaughter. Not long after this glorious success, Hinniades was feized with a fever, of which he died, at Zemlin, in September 1456, regarded as the hero of Christianism. Univ. Hist. Morenci.

HUNNIUS, Giles, a Lutheran divine, was born at Winende, in the duchy of Wirtemberg, in 1550. He was educated at Tubingen, and became professor of divinity at Marburg, from whence he removed to Wirtemberg. In these situations his zeal for Lutheranism led him to act in a manner that reflects much infamy on his memory. He excelled in all the requisites of a learned man. He was a man of considerable learning and abilities, but bigotted and intolerant. He was author of many controversial pieces: also of commentaries on the gospels; homilies, &c. His most celebrated work is entitled "Calvinus, Judairamus, &c." in which, says Bayle, Calvin was accused of so many heretical crimes that he might have been afraid of being treated like Servetus, he had lain at Hunnius's mercy. His works have been collected and published in five volumes, folio. Bayle.

HUNNOVER, in Geography, a town of Hindoostan, in Myfore; 15 miles E.N.E. of Cheremaypatam.

HUNS, in Ancient Geography and History, one of the northern nations, which, under the reign of Valens, threatened the empire of Rome, had been formidable, in a much earlier period, to the empire of China. Their ancient, perhaps their original seat, was an extensive, though dry and barren, tract of country, immediately on the north side of the great wall. These narrow limits, however, were extended by their valour; and their ruthless chiefs, who assumed the appellation of "Tanjou," gradually became the conquerors and the sovereigns of a formidable empire. Towards the east, their victorious arms were stopped only by the ocean; and the tribes, which are thinly scattered between the Amoor and the extreme peninsula of Corea, adhered with reluctance to the standard of the Huns. On the west, near the head of the Irish, and in the valleys of Imaus, they found a more ample space, and more numerous enemies. One of the lieutenants of the Tanjou subdued, in a sanguine expedition, 26 nations; and the Igours, or Vigoars, distinguished above the Tartar race by the use of letters, and consoling of three claffes, of hunters, shepherds, and husbandmen, were in the number of his vassals. On the north, the ocean was the limit of the power of the Huns. The pride of the Tanjou might be flattered by the submilion of so many distant nations; but the valour of the Huns fought the richer recompense of the wealth and luxury of the empire of the south. In the third century before the Christian era, a wall of 1500 miles in length was constructed in order to defend the frontiers of China against the inroads of the Huns; but this was an insufficient defence to an unwarlike people. The cavalry of the Tanjou frequently consisted of two or three hundred thousand men, formidable by the matchless dexterity with which they managed their bows and their horses; by their hardy patience in supporting the inclemency of the weather; and by the incredible speed of their march, seldom checked by torrents or precipices, by the deep rivers, or by the most lofty mountains. They spread
spread themselves over the face of the country; and notwithstanding the elaborate tactics of the Chinesse, directed in their operation by the emperors of Kioi, whose efforts had raised him to the throne, were constrained to surrender to the victorious arms of the barbarians. B. C. 201. The succellers of Kioi, whose lives were dedicated to the arts of peace, or the luxury of the palace, submitted to a more permanent disgrace, and to purchase a temporary and precarious peace by the regular payment of a tribute of money and silk. Besides, a select band of the fairest maidens of China was annually devoted to the rude embraces of the Huns; and the alliance of the haughty Tanjous was secured by their marriage with the genuine or adopted daughters of the imperial family, which valily attempted to escape the facriligious pollution. At length, however, the pride of the Huns was humbled, and their progress checked by the arms and policy of Vouti, the fifth emperor of the powerful dynasty of the Han. (B. C. 141–57.) Intimated by the arms, or allured by the promises of Vouti and his succellers, the most considerable tribes of the east and of the west declined the authority of the Tanjou. (B. C. 70.) The Tanjou was compelled to renounce the dignity of an independent sovereign, and the freedom of a warlike and high-spirited nation. From this period the monarchy of the Huns gradually declined, till it was broken, by civil difference, into two hostile and separate kingdoms. (A. D. 48.) One of the princes of the nation was urged, by fear and ambition, to retire towards the south with eight hordes, which composed between forty and fifty thousand families. He obtained, with the title of Tanjou, a convenient territory on the verge of the Chinese provinces; and his vassalage to the service of the empire was secured by weaknesses and the desire of revenge. From the time of this fatal schism, the Huns of the north continued to languish about 50 years, till they were oppressed on every side by their foreign and domestic enemies. The Sienpi, a tribe of oriental Tartars, retaliated the injuries which they had formerly sustained; and the power of the Tanjous, after a reign of 1300 years, was utterly destroyed before the end of the first century of the Christian era. (A. D. 93.) The era of the Huns is placed, by the Chinese, 1210 years before Chrilt, but the fates of their kings does not commence till the year 230. About this period more than 100,000 persons of the poorest condition, and most purulent temper were contented to remain in their native country, and to mingle with the victorious nation of the Sienpi. Fifty-eight hordes, consisting of about 100,000 men, ambitious of a more honourable servitude, retired towards the south, and were permitted to inhabit and to guard the extreme frontier of the province of Chans and the territory of Ormon. But the most warlike and powerful tribes of the Huns maintained, in their adverse fortune, the undaunted spirit of their ancestors; and resolved to explore the western world, and to discover some remote country, inaccessible to the arms of the Sienpi, and to the laws of China. In the course of their emigration they soon passed the mountains of Imaus and the limits of the Chinese geography. Of these formidable exiles two divisions directed their march towards the Oxus, and towards the Volga. The first of these colonies established their dominion in the fruitful and extensive plains of Sogdiana, on the eastern side of the Caspian, where they preferred the name of Huns, with the epithet of Euthalities, or Nephalities. Their manners were softened, and even their features were improved by the influences of the climate, and their long residence in a flourishing province, which may still retain a faint impression of the arts of Greece. These white Huns, a name which they derived from the change of their complexion, soon abandoned the pastoral life of Scythia, and though their vicinity to the provinces of Perisa involved them in frequent contests with the power of that monarchy, they respected, in peace, the faith of treaties; and, in war, the dictates of humanity. The second division of their countrymen, the Huns, who gradually advanced towards the north-west, were exercised by the hardships of a colder climate, and a more laborious march. Their independent spirits soon rejected the hereditary succession of the Tanjous; and while each herd was governed by its peculiar murfa, their tumultuary council directed the public measures of the whole nation. As late as the 13th century, their transient residence on the eastern banks of the Volga was attested by the name of Great Hungary. (See Hungary.) A chain occurs in their history after these Huns of the Volga were lost in the eras of the Chinese, and before they appeared to those of the Romans, which is not easily filled up. There is reason, however, to apprehend, that the fame force which had driven them from their native seats, still continued to impel their march towards the frontiers of Europe. The Huns, whose martial spirit had not been impaired by a long residence in China, with their flocks and herds, their wives and children, their dependents and allies, were transported to the coasts of the Volga; and they boldly advanced into the country of the Alani, a pastoral people who occupied, or waited, an extensive tract of the deserts of Scythia. (See Alans.) The Huns united with the Alani in their invasion of the Gothic empire. (A. D. 375.) The numbers, the strength, the rapid motions, and the imitable cruelty of the Huns were felt, and dreaded, and magnified by the almonified Goths, who beheld their fields and villages consumed with flames, and deluged with inhuman blood and slaughter. To these real terrors they added the surplice and abhorrence which were excited by the thrill voice, the uncouth gestures, and the strange deorimy of the Huns. These fages of Scythia were compared (and the picture had some resemblance) to the animals who walk very awkwardly on two legs; and to the mill-flapped figures, the "Termini," which were often placed on the bridges of antiquity. They were distinguished from the rest of the human species by their broad shoulders, flat noses, and small black eyes deeply buried in the head; and as they were almost deitute of beards, they never enjoyed either the manly grace of youth, or the venerable aspect of age. A fabulous origin was assigned to them, worthy of their form and manners; that the witches of Scythia, who, for their foul and deadly practices, had been driven from society, had opulized in the desert with infernal spirits; and that the Huns were the offspring of this execrable conjunction. The Goths greedily embraced the tale, and were the more easily induced to exert themselves in repelling the invasion of such enemies. (See Goths.) Such is the character, with the addition of many other particulars, which Amianus Marcellinus and Jornandes give of these Scythis and Sarmatian Huns, who anciently inhabited that part of Asiatic Sarmatia, which bordered on the Palus Mecitus and the Tanais, the ancient boundary between Europe and Asia. They are represented as the most savage and cruel of all the barbarous nations. Their cheeks were mangled and countenances distorted in their earliest infancy, with a view, in manner age, of striking terror into their enemies. They lived in the open air, without house or even huts, and subsisted on roots and raw meat; and incurred themselves, in the woods and on the mountains which they inhabited, to every kind of privation and hardship. They were accustomed to eat and to sleep on horseback, scarcely ever dismounting; and they covered their nakedness with goat-skins, or the skins of
of a fort of mice fewed together. They had no law, nor any kind of religion; nor did they observe any distinction between good and evil, or submit their inclinations and passions to any kind of restraint. In war, they began the battle with great fury and a hideous noise; but after the first onset, their fury abated and they fled, when refraffed, in the greatest confusion. They were notoriously faithless, so that they disregarded the most solemn treaties. Sometimes they made incursions into the Roman empire in defiance of the most sacred oaths and engagements; and at other times they joined the Romans in fighting against the Goths, and other barbarous nations. They have fought against each other when they had prospect of gaining any advantage to themselves by such conduct. Of their disposition in this respect, Julianus was so fully apprised, that by promising a large sum to the Uturugiriun Huns, who inhabited the south side of the Palus Mæotis, he prevailed upon them to fall upon the Uturugiriun, another tribe, which had occupied the territory north of the others, towards the Tanais. Their form of government was not strictly monarchical; but they were headed and conducted by some of their chiefs. It was about the year 376 that they entered the country of the Alans, and, obliging those who survived their cruelty to enroll under their standard, fell upon the Goths, called by Ammianus Greuthongi, and by Jornanes Ælrogothi, and drove them out of their country. The Visigoths were afterwards treated in the same manner. The Gothic nations, alarmed by the sudden and unexpected irruptions of the Huns, determined to abandon their territories, and to seek shelter within the Roman dominions, separated by the Danube from the countries which had been over-run by the Huns. Upon submissive application to Valens, the Goths were admitted into Thrace, and their number was so considerable, that Ammianus compares them to the spars which at that very time issued out of Mount Ætna, and to the sands of the Libyan shore. Thus the Huns, in the year 376, not only settled in Europe, but made themselves masters of that immense country, which extends from the Tanais to the Danube, and which, before their arrival, was possessed by the Alans, the Goths, and several other barbarous nations, whom they either drove out, or forced to submit to their victorious arms.

In the year 388, many of the Huns, who had settled in Europe, were induced by large sums to enlist under the Roman banner of Theodosius I., who was then emperor, and they were thus prevented from raising disturbances on the frontiers of the empire. In 391 they passed the Danube, and being joined by the Goths and other barbarians, committed dreadful havoc in Media and Thrace; but their progress was restrained by the vigorous and successful attack of Stilicho.

About four years after, viz. in 395, the Huns made an unexpected inroad into the eastern provinces, and penetrated as far as Antioch, destroying the country with fire and sword, and committing every where deplorable cruelties. Having overrun and plundered several provinces, they voluntarily returned home, loaded with spoil, and carrying with them an incredible number of captives. After this irruption they remained quiet for nine years, or till the year 404, when passing the Danube in great multitudes, they entered Thrace, and having traversed that province, penetrated into East Illyricum, committing wherever they went dreadful ravages. In the following year great numbers of them entered the Roman service, and joined Stilicho's army, in its march against Radagaisus, who had invaded Italy. They were led by Udin, one of their chiefs, and contributed to the victory gained by Stilicho in Etruria; but in two years after the signal victory, obtained chiefly by his means over Radagaisus, Udin became an irreconcilable enemy to the Romans; and passing the Danube, entered Thrace at the head of a numerous army; but having offended some of his principal officers, who joined the Romans, he was forced to recons the Danube after having lost many of his men. From this period the Huns seem to have continued quiet till the year 423, when, upon the death of the emperor Honorius, John, his chief secretary, assumed the purple, and the celebrated Actius (see his article) was prevailed upon to offer the cæsar of the Huns to march to the assistance of the new emperor; but hearing of his death, the prudent leader submitted to Theodosius, and persuaded the Huns, not without distraining among them considerable sums, to return home. Soon after this event, which happened in 423, we find the Huns in possession of Pannonia. As they were much indebted to Actius for the lands they held in this country, Ross, their chief or king, received this able commander with the greatest demonstrations of kindness and friendship, upon his being disgraced at the court of Placidia, mother of Valentinian III. and sent him back at the head of a powerful army of Huns, which so terrified Placidia, that she restored Actius to all his employments, and raised him to the rank of patrician. In 435 a strong body of Huns marched through Germany and Gaul, and joined Actius against the Burgundians, who, having been allowed to settle in that part which bordered on the Rhine, had revolted from the Romans, and ravaged Belgic Gaul. On this occasion 20,000 Burgundians, with their commander Gondicacius, were cut off. Soon after the Burgundians marched against the Huns, and surprizing them when they were left destitute of a leader, by the sudden death of Uptar, their king, destroyed 10,000 of them, and obliged the survivors to save themselves by a precipitate flight. The Huns, notwithstanding this defeat, marched either in the same or the following year to the assistance of the Romans against the Goths, who had been allowed to settle in Aquitain, but who, not contented with the territory allotted to them, had taken possession of several cities belonging to the Romans, and had laid siege to Narbonne. The Huns, having in the preceding year signalized themselves against the Goths in Asia, marched against the Goths of Aquitain. In 435 Ross, or Ross, king of the Huns, concluded a peace with Theodosius II., of which one of the conditions was, that the emperor should pay him a yearly pension of 350 pounds weight of gold. Soon after Ross died, and was succeeded by his two nephews, Bleda and Attila. For the principal events that occurred under the reign of Attila, we refer to his biographical article. With the death of Attila the empire of the Huns is said to have terminated; for after this event they were fo weakened by intestine wars and by the interruptions of the Gepida and Goths, that they continued quiet till the year 466, when passing the Danube on the ice, they made an incursion into Dacia, and committed dreadful ravages in that country. But their progress was interrupted by Anthemius the Roman commander, and in a pitched battle they were totally defeated. The Huns, dispirited by their losses and the death of their leader, were not in a condition to molest either the Romans or their neighbours for about 60 years.

In 526 Boar, queen of the Huns, took part with the Romans against the Persians, and led to the assistance of the emperor Julianian an army of 100,000 men, and obtained a victory, in the 11th year of Julianian's reign. The Huns, passing the Danube in great multitudes, laid waste Thrace, Greece, Illyricum, and all the provinces from the Ionian sea to the suburbs of Constantinople; and having crossed the Hellenefont, extended their ravages to Asia, whence, after practising unheard-of cruelties, they returned home loaded with an immense booty. Julianian, in order to keep them quiet, allowed them some lands in Thrace, and agreed
HUNGRIOUS and professional private, Audi Austria in May his works, their particulars, and a small congregation, to which is annexed a Dissertation on the Fall of Man." After his death four volumes of his "Sermons," with tracts, were published, to which was prefixed Dr. Lardner's Funeral Sermon for him: to this the reader is referred for farther particulars.

Hunt, Mrs. Arabella, a lady much celebrated the latter end of the 17th century, for her beauty, fine voice, and musical talents. Congreve has left a rapturous and exaltative ode on her performance, which, if not erapheically exquisitely, his verses must be the most mendacious, that is, the most poetical, that ever were written. It seems the most animated of all the author's fugitive pieces; and we should suppose that he felt strongly what he so warmly describes.

If matters of fact in our biographical articles were not more our business than amusement of our readers, we should infest this whole poem, as it surpassest in intelligible panegyric all that ancient poets have laid of the miraculous powers of Orpheus, Amphion, or Linus. We cannot help giving the first strophe as a specimen of auricular rapture.

On Mrs. Arabella Hunt singing, "Let all be hushed, each softest motion cease, Be every loud tumultuous thought at peace, And every ruder gap of breath Be calm as in the arms of death."

"And thou most sickle, most uneasy part, Thou restless wanderer, my heart, Be still; gently, ah, gently leave, Thou busy idle thing, to heave. Stir not a pulse, and let my blood, That turbulent unruful flood, Be fully fluid."

"Let me be all, but my attention, dead. Go, rest, unnecessary springs of life, Leave your officious toil and strife, For I would hear her voice, and try If it be possible to die, &c." Whether this siren was a professional singer, or a lady, does not appear; she was contemporary with Purcell, and gained her musical fame chiefly by her admirable performance of his compositions. She taught the princesses Anne of Denmark to sing; and was in such favour with queen Mary, that she bestowed on her an employment in the household, for the sake of having near her perchon, and was frequently entertained by her performance in private, even in singing to her majesty common popular songs and ballads.

Old Mr. Gotchlin of Canterbury, used to relate a story which he had from his father, (one of the priests of the chapel royal, fabdean of St. Paul's in the time of Charles II. and in the reign of king William, a favourite singer at court,) that queen Mary having expressed herself warmly in favour of the old Scots tune of "Cold and raw the wind doth blow," Purcell made it a perpetual bane to an air in the next birth-day ode, 1692; beginning "May her blest example chase:" a piece of pleasantry occasioned by her majesty asking for this tune, after he, (Gotchlin,) and Mrs. Arabella Hunt, with Purcell to accompany them on the harpsichord, had exerted all their talents and abilities to amuse so great a personage with compositions which they mistakenly thought of a superior class.

Mrs. Hunt died in 1705, when Congreve, under her picture playing on the lute by Sir Godfrey Kneller, furnished the following lines, which in his works are called an epigram.

"Were there on earth another voice like thine, Another hand to blest with skilful divine; The late afflicted world some hopes might have, And harmony retrieve thee from the grave."
May, 1718, at Kilbride, in the county of Lanark, in Scotland. His father, John Hunter, was defended from the family of Hunter of Hunterstown, and refided on a small estate, called Long Calderwood, in the parish of Kilbride. William, the seventh of ten children, was of a quiet and diligent disposition, and was sent to the university of Glasgow, at the age of fourteen, as a student of divinity. But after a short study of theology, he conceived a repugnance to the subject, and transferred the subscription to the articles of the Scotch church; and in this state of mind becoming acquainted with Mr. Cullen (afterwards the celebrated profeflor at Edinburgh), who had just settled in practice at Hamilton, he was led to give a preference to the profession of physic, and in 1737 went to reside with this excellent friend and preceptor, with the consent of his father. The three years which he paffed at Hamilton, he often declared were the happiest in his life. Mr. Cullen and he entered into partnership, with this liberal agreement, that each of them should alternately purfue further improvement in some medical school. Hunter, in consequence, went to Edinburgh in November 1740, where he attended the winter course of lectures, and among others that of the firft Dr. Alexander Monro. In the summer of 1741, he removed to London, with a recommendation to Dr. James Douglas, who was at that time engaged in a great anatomical work on the bones, which he did not live to complete. He was desirous of engaging a young man of abilities and industry to affift him in his diflrefions, and being favourably impressed with the conversation of Mr. Hunter, invited him to reside in his family for that purpose, and also to fouperintend the education of his fon. Dr. Cullen readily gave his affent to a change of plan so favourable to his friend's advancement; and his venerable father, then near his end, reluctantly confoled; he died in October of the same year. Mr. Hunter was immediately enabled, by Dr. Douglas's friendly affiftance, to enter himself as a furgeon's pupil at St. George's hospital, and as a diflrefing pupil of Dr. Frank Nichols, an anatomist of considerable reputation. He purfued his diflrefions with fuch afpidity and fuccefs, that Dr. Douglas was at the expence of having several of his preparations engraved. But he foon had the misfortune to lose this generous friend, who died in April 1742. He continued, however, to reside with the doctor's family, and to purfue his studies with the fame diligence: for while he was convinced that he must now depend upon his own exertions for professional fuccefs, he also began to feel a confidération of his own powers. In the following year, 1743, he communicated to the Royal Society a paper "On the Structure and Diffufes of articulating Cartilages," which was printed in their Transactions, vol. 43, and was admired for the ingenuity of the obervations on a subject not much inquired before. He now determined to become a teacher of anatomy; but difficulties at firft prevented himself, and he was difcouraged by Dr. Nichols, who about that time declined giving lectures in favour of Dr. Lawrence. A circumftance, however, soon occurred, which called forth his abilities in this way. A society of navy-furgones had engaged Mr. Samuel Sharpe to deliver to them a coufe of lectures on the operations of surgery, at an apartment which they had in Covent-Garden. Mr. Sharpe at this time declined the task, and Mr. Hunter was solicited to continue it, which he did fo much to their satisfaction, that they requed him to extend his plan to anatomy; and in the winter of 1746, he began his course of anatomical lectures in their room. At firft he experienced considerable difidence in preaching to a public; but at length his diligence was over- come, and he acquired that facility for which he was peculiarly distinguished, and which rendered the delivery of lectures a source of real pleafure to him. We may here mention, that on returning home after his introductory lecture, accompanied by a young friend, Mr. Hunter, who had received about twenty guineas from his pupils, and had got the money in a bag under his cloak, observed, that it was larger than he had ever been matter of before: an anecdote which, as Dr. Simmson remarks, deferves to be recollected as an encouragement to young men, who with great merit poifefs but little advantages of fortune. Considerable as the emoluments of his two firft courses were, by contributing to the wants of different friends, he found, himself, at the return of the next fefon, obliged to defer his lectures for a fortnight, merely because he had not money enough to defray the neceffary expense of advertisements. This produced a reolution to be in future as cautious in lending money, as he was averse to borrowing it. His own habits were strictly economical, and laid the foundation of that ample fortune, which he fo freely expended upon objects of public utility.

In the spring of 1748, he set out on a tour through Holland to Paris, with his pupil young Douglas. The only circumstance recorded of this journey, is his introduction to the celebrated Albinus at Leyden: whole admirable injections inspired him with a ftrong emulation to excel in that curious and important part of anatomy. Although admitted into the corporation of surgeons in the preceding year, he now relinquifhed that branch of practice, to which he had always a ftrong averter, and directed his views to the practice of midwifery, in which his patron Dr. Douglas had acquired confiderable reputation. His advancement in this department was accelerated by his being elected furgeon-accoucheur firft to the Middlesex, and fon afterwards to the British Lying-in-hospital, as well as by the delicacy of his perfon and manners, which gave a great advantage over his countryman, Dr. Smellie. He was likewise recommended by several of the moft eminent furgones of that time, from a respect for his anatomical talents; and the death of Sir Richard Manningham, and the retirement of Dr. Sandy's, (who then had the moft lucrative practice in that branch,) concurred to affift Mr. Hunter's progress. In 1750, he obtained the degree of M. D. from Glasgow; and as his reputation increased, he was much confeffed as a physician, both in cafes connected with his particular branch of practice, and in those which required peculiar anatomical skill in their investigation. About this time he quitted the family of Mrs. Douglas, and took a houfe in Jeremy-street.

In 1751, Dr. Hunter revived his native country; but with the exception of this journey, to which he devoted only a few weeks, he was never afient from London but under professional engagements. In 1756 he was admitted a licentiate of the College of Physicians, and fon afterwards was elected a member of the Medical Society, recently instituted; the "Medical Observations and Inquiries" of which he enriched by many valuable communications, and of which he was deservedly chosen president on the death of Dr. Fothergill. It will be fufficient here to notice the moft important of the contributions to medical science, of which Dr. Hunter was the author, in the excellent volumes publifhed by this society. In his history of an aneurism of the aorta, contained in the firft volume, 1757, he was the firft to notice a peculiar form of this difeafe, occasioned by the winding of an artery through a vein, with which vefel, after healing externally, the artery continues to maintain a communication. Of this difeafe he afterwards treated more at large (see Med. Obst. and Inquir. vol. ii. and iv.); and it has been since named aneurismal varis, at the figuration of Dr.
Dr. Cleggorn. (Ibid. vol. iii.) In the second volume, among several other papers, is the description of a case of emphysema, followed by some judicious practical remarks on the cellular membrane and its diseases. He here maintained the opinion that the vesicles, in which the fat is deposited, are diffuse cells that depend on the excretory system. In the fourth and fifth volumes he communicated his valuable observations relative to the retroversion of the uterus, which sometimes occurs in pregnancy, and is liable to produce a fatal event, if not remedied in time; a disease not understood till accurately described by Dr. Hunter. All his papers, published in the volumes alluded to, are worthy of attention.

In the year 1762 Dr. Hunter came forward as a controversialist, and with a degree of acuteness, which has very commonly attended anatomical controversies, maintained his claims to different anatomical discoverers. In his "Medical Commentaries," to which a "Supplement" was afterward added, he supported the priority of his discoveries over those of Dr. Monro, jun. professor of anatomy at Edinburgh, in respect to the ducts of the lachrymal glands, injections of the telseicle, the origin and use of the lymphatic vessels, and absorption of the veins. There is nothing more difficult to ascertain, as Dr. Aikin has justly observed (Gen. Biog.), than the exact share in the improvements of a progressive science, due to the individuals who are simultaneously pursuing it, with equal arduous and advantages; nor is the determination of any consequence to the science itself. The great doctrine of the absorbent action of the lymphatic system, which is now fully received, at least by the anatomists of Great Britain, was taught and illustrated at the same time in the schools of London and of Edinburgh, and excelled the ingenuity of Hunter, Monro, Hewson, Cruickshank, and other anatomists. Dr. Simmons has shewn, however, that the principal points of this system had been stated, so long ago as the year 1716, by Mr. Nogues, in the second edition of his work entitled "L'Anatomie du Corps de l'Homme en abrégé," printed at Paris. Who may have first succeeded in a lucky discovery seems a matter far less worthy of contest; but Dr. Hunter was extremely tenacious of any claims of this kind, and would not suffer the interference even of his own brother. Some papers, in which a claim of Mr. John Hunter, relative to the connection between the placenta and uterus, was disputed by the doctor in 1780, are preserved in the archives of the Royal Society. In the "Commentaries" there are also some observations on the insensibility of the dura mater, peritoineum, tendons, and ligaments, as taught with some flight of reasoning by Haller; and likewise "Observations on the State of the Tissue in the Fetus, and on the Hernia Congenita, by Mr. John Hunter."
The professional reputation which Dr. Hunter had already attained was evinced by his being consulted in the pregnancy of the queen, in 1762. Two years afterwards he was appointed physician extraordinary to her majesty; a distinction for which he was indebted solely to his personal merit. In 1767 he was elected a fellow of the Royal Society; and in the following year he communicated to that body some observations on the bones found near the river Ohio, in America, which were commonly supposed to belong to the elephant. But he proved, chiefly from the structure of the teeth, that they belonged to some unknown quadruped, of a different species. (Phil. Trans. vol. 58.) In the 6th and 61st volumes of the same publication, were printed a memoir on some fossil bones, found in the rock of Gibraltar, and an account of the Nyl-gan, a non-defert Indian animal. In 1768, Dr. Hunter was elected to the Society of Antiquaries, and was appointed by his majesty to the office of professor of anatomy in the Royal Academy of Arts, on its first institution. This appointment opened a new field for the application of his anatomical knowledge, in relation to external form, as the object of painting and sculpture. He engaged in it, in every other pursuit of his life, with unremitting zeal, and the novelty and ingenuity of his observations displayed the extent of his talents. Finally, he received other literary honours from learned societies abroad; being chosen a foreign associate of the Royal Medical Society of Paris in 1782, and of the Royal Academy of Sciences, in the same city, in 1782. So early as the year 1751, Dr. Hunter had commenced a work, upon which he continued to bestow incessant attention and great expense for several subliterate years; this was his splendid publication, "The Anatomy of the Gravid Uterus," which appeared in 1775, illustrated by 34 large engravings, executed from capital drawings of subjects and preparations, by the first masters. This great work, not less admirable for its accuracy than for its magnificence, exhibited all the principal changes that occur in the nine months of pregnancy, in a degree of perfection which had never before been approached. In this work he first delineated the retroverted uterus, and the membranes decidua reflexa, which he himself discovered. He drew up a detailed anatomical description of the figures, which he did not live to finish, but which was completed and published by his nephew, Dr. Baillie, in 1794, under the title of "Anatomical Description of the Gravid Uterus and its Contents." In 1778 he published his "Reflections on the Section of the Symphysis Pubis," an operation introduced by the French, but which the cooler judgment of English practitioners rejected upon the most solid grounds. Among Dr. Hunter's papers were found "Two Introductory Lectures" to his anatomical course, correctly written out, which were published in 1780, in 1785, and which complete the catalogue of his publications.

Having followed the course of Dr. Hunter's labours as a teacher and writer, we must go back a little in order to trace his progress in the foundation of a museum, which he defined for public use. His first desire, when he commenced the practice of midwifery, was to acquire a sufficient fortune to secure him safe and independence; and in a few years he found himself in possession of this competency. As his wealth continued to accumulate, he formed the laudable design of employing his superfluity in some scheme of public utility; and the foundation of an anatomical school in the metropolis naturally suggested itself. About the year 1765, therefore, he presented a memorial to the miniror, Mr. Grenville, requesting a grant of ground in the King's Mews, on which he offered to build a proper edifice at the expense of seven thousand pounds, and to endow a professorship of anatomy in perpetuity. This offer was received coldly; and after some delay Dr. Hunter purchased a spot of ground in Great Windmill street, on which he built a house, together with an anatomical theatre, and a museum, and removed thither from Jermyn street in 1770. The first furniture of the museum consisted of an extensive collection of anatomical preparations, formed with great labour and expense; to which, however, he now added fossils, shells, and other objects of natural history; a great treasure of Greek and Latin books in the rarest editions; and, lastly, a cabinet of ancient coins and medals, which was collected pregressively at the expense of upwards of 20,000l. A description of part of the coins, in this collection, struck by the few Greek cities, was published by his friend Mr. (now Dr.) Combe, under the title of "Nummorum Veterum Populorum et Urbium, qui in Museo Gulielmi Hunter attorrentur, descrip.tio, figuris illustrata Opera et studio Caroli Combi, S. R. et S. A. Vol. XVIII."
Hunter.

Soc. 1783. An early access was always given to persons who wished to view and consult this museum, and its reputation among foreigners reflected honour upon the capital containing it.

Dr. Hunter continued to teach and to practise in his profession, with unabated affinity, until March 1783, when an attack of a wandering gout, to which he was subject, obliged him to keep to the house for some days. A partial recovery induced him, contrary to the advice of his friends, to deliver a lecture; but the effort so much exhausted him that he fainted away, and a flight paralytic attack followed in the night. His intellects remained clear, however, until death, and he surveyed its approach with so much tranquillity, that in his last moments he said to Mr. Combe, "If I had strength enough to hold a pen, I would write how easy and pleasant a thing it is to die." He expired on the 32d of March 1783.

In person Dr. Hunter was slender, and rather below the middle stature. He was a man of mild and sedate character, easy in conversation, engaging in his address, ready in the pursuit of his objects, simple and regular in his mode of life. As a practitioner he was cautious, perhaps to the verge of timidity; but singularly qualified to inspire confidence in his patients. As a lecturer he peculiarly excelled in the clearness of his demonstrations. No man has so much contributed to the propagation of useful knowledge in this kingdom, and to the reputation of London as a school for that science. By his will he bequested to his nephew, Matthew Baillie, M. D. (his successor as a teacher of anatomy, and now the most eminent physician in the metropolis, 1816,) his museum, for a term of 30 years, with a sum for its augmentation, and annuities to three trustees for the care of it, while in London. At the end of that period it was to go to Glasgow; but Dr. Baillie has already had it removed to that university some years before the completion of that term. See an Account of the life, &c. of Wm. Hunter, M. D. by Dr. S. F. Simmons, 1783. Gen. Biog.

Hunter, John, a very eminent surgeon, brother of the preceding, and youngest of the family, was born in July 1728. Being his mother's favourite, and his father, through age and indisposition, being unable to pay much attention to him, he was brought up in a course of indulgence, which proved injurious both to his temper and his progress in learning. It was late and with great difficulty that he was taught to read; and after his father's death, he was left, at the age of 15, an ill-governed boy, neglecting his education, and spending his time in idleness and country amusements. Yet he exhibited marks of an acute understanding and of a bold disposition. As he appeared to have a mechanical turn, and some manual dexterity, he was sent to Mr. Buchanan, a brother-in-law, lately settled in Glasgow, as a carpenter and cabinet-maker; but the want of success in this profession's business left young Hunter again unemployed. Having heard of the reputation which his brother William was now acquiring in London, he wrote to request permission to visit him, and to try to make himself useful as an anatomical assistant, or, if that should be refused, to enter the army. The offer was readily embraced by William, and John arrived in London in September 1748, just before the commencement of the winter course of lectures. John's first essays in dissection satisfied his brother of the certainty of his ultimate proficiency in anatomy, which he cultivated with such success, as to be capable of undertaking the demonstrations to the pupils in the dissecting room in the following winter. In the summer months he attended the practice of surgery at the Chelsea hospital, under Mr. Cheffelden, and afterwards at St. Bartholomew's and St. George's hospitals, of which

He was appointed house-surgeon in 1756. It does not appear with what intention he was entered as a gentleman-commoner at St. Mary's hall, Oxford, in 1753. Literary distinction seems never to have been his ambition; nor indeed within his reach. This probably he soon discovered; for we find no intermission of his professional pursuits in London. In the winter of 1755, Dr. Hunter admitted him to a partnership in his lectures. He applied himself to dissection, and to making anatomical preparations, with unexampled ardour and perseverance, in which he was highly useful to his brother's collection. Having thus laboured for ten years in the investigation of human anatomy, he turned his inquiries to the anatomy of other animals, with a view to elucidate the use of the different organs, by a comparative view of their structure, and thus to acquire a more certain knowledge of the general principles of the animal economy. He prosecuted these researches with the ardour of an enthusiast, and suffered no opportunity of examining animals of every description to escape him. His health was so much impaired, however, by this active application, that in the year 1760 he went abroad as surgeon on the staff, and served during the war in Baille-fille and in Portugal, where he acquired his knowledge of gunshot wounds. On his return in 1763, he settled as a surgeon in London, and added to the scanty income derived from his practice, by teaching practical anatomy and operative surgery for several years. His ardour for comparative anatomy continued unabated; and for the greater facility of carrying on his experiments, he purchased a piece of ground at Earl's Court, Brompton, where he built a house. Here he kept several foreign animals, of whose manners and habits he was a sedulous observer, and subsequently made his observations and experiments relative to the economy of the bee, the filkworm, and other insects; to the progress of incubation in the egg; to the growth of vegetables; to the transplanting of teeth into the combs of cocks, &c. &c. with the description of which he enriched the volumes of the Philosophical Transactions, and with his preparations formed that unrivalled museum, of which we shall presently speak. He was elected a member of the Royal Society in 1767; and, in order to promote scientific improvement more effectually than could be done by formal meetings, he was the means of associating some of the most active members in a conversational society in a coffee-house, after the public business of the society was ended. This at first consisted only of Dr. G. Fordeye, Mr. Cumming, and himself; but they were soon joined by Sir Joseph Banks, Dr. Solander, Dr. Mackelyne, &c.

When Dr. Hunter removed to his new establishment in Windmill-street, he assigned the lease of his house in Jermyn-street to Mr. Hunter. "About the same time Mr. Hunter became a member of the corporation of surgeons, and, through his brother's interest, was elected one of the surgeons to St. George's hospital. In 1771, finding his assistance increasing with his reputation, he married a lady to whom he had been long engaged, the eldest daughter of Mr. Home, a military surgeon, and flifer to the present Mr. Everard Home. She was a person of elegant accomplishments, and has lately obliged the public with a volume of poems. His house was now frequented by medical students, who came to finish their education in London, and who were defirous of a residence in a situation favourable to their improvement. Among others of his pupils, who have since attained to professional eminence, we may mention the name of Jenner, immortalized by the discovery of the preventive powers of the cow-pox. In 1771 he published his first work, "On the Natural History of the Teeth," in 4to. It displayed great accuracy of research, and was illustrated with excellent plates. In 1773 he commenced a course of lectures on the theory and
principles of surgery, in which he brought forward many peculiar opinions, exprest in a peculiar language, which he introduced into physiological and pathological science. Part of the peculiarity of his language, however, must be attributed to his want of a regular literary education, and arose from his misconception of its proper use; and to the same defect must be ascribed his failure to acquire that methodical arrangement of his ideas, and clearness and facility in expresting them, for which his brother was so much distinguished. However, he was a real improver of his profession, both in a theoretical and practical view. He suggested new methods of treatment in ruptures of the tendo Achilles, in the operation for hydrocele, and for fistula lachrymalis, &c.; but the most important of his chirurgical improvements was the method of operating for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh.

In the year 1776, Mr. Hunter was appointed surgeon-extraordinary to his majesty. In 1778 he published the second, or practical part, of his "Treatise on the Teeth," in which their diseases were considered. Soon afterwards, he was elected a member of the Royal Society of Gottenburgh, and of the Royal Medical Society, and Royal Academy of Surgery, at Paris. In the year 1783, the term of his service in the termi-street expired, and his collection being now too large to be contained in his dwelling-house, he purchased the lease of a large house on the east side of Leicester-square, with premises extending to Castle-street, on which he erected a spacious building for his museum, at a cost much beyond the dictates of prudence. Had his age and state of health, indeed, justified the expectation of a long continuance of the emoluments which were beginning to flow in upon him, no expenditure connected with his fame could have been thought censurable. At this period his faculties of body and mind seem to have been exerted to the utmost, and every moment had its full employ. He was now engaged in a very extensive private practice; he was surgeon to St. George's hospital; he was giving a long course of lectures in the winter; he was carrying on his inquiries in comparative anatomy, and adding to his museum; he had a school of practical anatomy in his own house, and was constantly employed in some experiments respecting the animal economy. The post of deputy surgeon-general to the army was conferred upon him in 1786; and in the same year his great and long-expected work "On the Venereal Disease" made its appearance. Few medical performances have been more read; but it underwent some severe criticisms, both theoretical and practical: nevertheless it will ever remain a monument to his extraordinary sagacity and talent of observation. He also published in this year, "Observations on various Parts of the Animal Economy," chiefly composed of papers already printed in the Philosophical Transactions. In the spring of this year Mr. Hunter was seized with a severe illness, from which he recovered slowly, and which left his constitution impaired; he became subject especially to an affection of the heart, which came on upon every violent agitation of the mind, or sudden exertion of the body. In 1790 he was appointed inspector-general of hospitals, and surgeon-general to the army, which gave him much additional occupation; and he then resigned his course of lectures to his brother-in-law, Mr. Home, still employing all his little leisure in scientific pursuits. From the autumn of this year, however, the series of spasmotic and other uneasy symptoms, connected with the affection of the heart, and constituting what is named angina pectoris, which had for some time harassed him, increased considerably in violence, and to himself and others portended a suddenly fatal termination.

During the years 1791 and 1792, he had many severe attacks, but of not more than a few hours duration. On the 10th of September 1793, in his usual state of health, he went to St. George's hospital, where something occurred which irritated him, but of the circumstances of which he was not perfectly master. He therefore withheld his sentiments, and withdrew into the next room, where, in the act of turning round to one of the physicians, he gave a deep groan, and dropped down dead.

On dissection, the heart was found to be the principal seat of disease. That organ appeared as if shrunk in its size; the coronary arteries, which ramify in its substance, were completely ossified, or in the state of bony tubes; and the valves were in a state of incipient calcification.

Mr. Hunter was a man of a warm-and impatient temper, but open and unreserved. He was naturally cheerful and social; and his countenance bore the stamp of frankness and animation, though in his latter years it was deeply impressed with thoughtfulnes. The admirable print of him, from a portrait by Sir Joshua Reynolds, strongly confirms the judgment made of it by Lavater: "This man thinks for himself." In originality of genius and powers of investigation, he appears to have surpassed his brother; industry and perseverance equally belonged to both.

In order to avoid interruption to the biographical narrative, we have omitted to notice the very numerous and important papers which Mr. Hunter prefaced to the Royal Society, in rapid succession, especially between the years 1773 and 1783, chiefly relating to comparative anatomy and physiology; nor have we room to enumerate their titles. His fame, however, will principally rest upon his various discoveries in this branch of science; and it would be injustice to his character not to describe, as amply as our limits will admit, the anatomical museum, the formation of which may be regarded as having been the main object of his life. In its plan it was absolutely unique, and the perfection to which he brought it rendered it the admiration of all who were capable of judging of its value. It embraced the grand design of expounding the gradations of nature, from the most simple flake in which life is found to exist, to the most perfect and complete piece of animal mechanism, that of man. This collection of anatomical facts is arranged according to the functions they are intended to illustrate, the different parts of animal bodies intended for similar uses being brought together in series, so that the various links in the chain of perfection are readily followed, and clearly understood. This arrangement comprehends four great orders: the first, parts constructed for motion; second, parts essential to animals reflecting their own internal economy and preservation; third, parts superadded for purposes connected with external objects; and, fourth, parts for the propagation of the species, and the maintenance of the young. The first order exhibits the fluids of living bodies in a series, from the simple colourless sap of some vegetables to the coloured and coagulating blood; the muscles, from the straight simple muscle to the most complicated structure with elastic ligaments; the growth of bone, horn, shell, &c.; and the varieties of joints. The second order comprehends the organs of digestion, beginning with the hydatid, which is itself a simple pouch, and passing to the polypus, the leech, and more complicated animals, including a series of stomachs, of intestinal canals, and of the glands connected with them, as liver, spleen, &c. After the organs of digestion follow the system of absorbing vessels, from the roots of plants up to the lacteals and lymphatics of different animals. The next step is to the heart, which, in the caterpillar is a simple canal, and receives various additions as we ascend.
afscend in the scale, until we find it a double heart in man and quadrupeds; this leads to the structure of arteries and veins. Then the lungs are shown in all their gradations, from the simple vascular lining of the egg-shell, which serves as lungs for the chicken, to those of the most perfect animals, including gills, &c. The windpipe and organs of voice are shown under their different forms. And, finally, the kidneys are exhibited, which secrete the saporous fluids from the circulation. The third order takes up the brain from its simplest state in the leech, to the snail, insects, fish, &c. upwards;—the varieties of all the organs of senses in the different tribes of living things; and, finally, the external coverings of hair, feathers, &c.; the weariness of offence and defence, as furs, boots, horns, fings, and electric organs. As an appendix to this order, some peculiar structures are added, such as the air-bladder in fish, &c. The fourth order includes all the variety of parts connected with the processes of generation in plants and animals, from the polypus and coral, to the perfect animals,—those of females in the maiden and impregnated state, including the products of seeds, spawn, eggs, &c.; the progress of incubation; the peculiarities of the focus; and the various organs for the nourishment of the young. This sketch gives a very inadequate idea of the amazing number of objects, from every department of nature, which the collection comprised; but it contains, besides, a large series of whole animals, arranged according to their internal functions, which were, at the rarest ever brought into this country; such as the camelopard, hippocampus, &c. It comprehends, moreover, a series of skins of different animals, and skeletons of almost every known genus,—an immense number of calculi, urinaries, biliary, and intestinal; a large collection of shells and insec ts;—and a most complete assortment of extraneous fossils. By his will, Mr. Hunter directed that this museum should be offered to the public for the sum of £5,000, and given to the college of surgeons, on condition of exposing it to public view on certain days in the week, and giving a set of annual lectures explanatory of its contents. A large building for its reception has been completed in Portugal-street, connected with the college of surgeons, in Lincoln's-Inn-Fields; and in the spring of the present year (1810) the first course of lectures was delivered by Mr. Home and Mr. William Blizzard.

At the time of his death, Mr. Hunter had made considerable progress in the printing of "A Treatise on the Blood, Inflammation, and Gun-shot Wounds," which was published in 1794, under the inspection of Mr. Home, who prefixed a biographical account of the author. See this Account; also Gen. Biog.

HUNTER, Henry, a popular preacher and writer, was born at Culros, in Perthshire, in the year 1741. He had the best education that the circumstances of his parents would permit, and at the age of thirteen was sent to the university of Edinburgh, where, by his talents and proficiency, he attracted the notice of the professors, and, at the age of seventeen, he was appointed tutor to Mr. Bofwell, afterwards one of the lords of seilin. When he left Edinburgh he accepted the office of tutor to Lord Dunonald's sons at Culros abbey. In 1764, he was licensed to preach, having passed the several trials with great applause; and very quickly became much followed on account of his popular pulpit talents. He was ordained in 1766, and was appointed minister of South Leith. On a visit to London in 1769, he preached in moit of the Scotch meeting-houses with great acceptance, and soon after his return he received an invitation to become pastor of the Scotch church in Swallow-street, which he declined; but in 1771 he removed to London, and undertook the pastoral office in the Scotch church at London Wall. He appeared first as an author in 1783, by the commencement of his "Sacred Biography," which was at length extended to seven volumes octavo. While this work was in the course of publication, he engaged in the translation of Lavater's "Essays on Physoiogy," and in order to render his work as complete as possible, he took a journey into Switzerland, for the purpose of procuring information from Lavater himself. He attained, in some measure, his object, though the author did not receive him with the cordiality which he expected, suspecting that the English version must injure the sale of the French translation. The first number of this work was published in the year 1789, and it was finished in a style of respectability worthy the improved state of the arts. From this period Dr. Hunter spent much of his time in translating different works from the French language. In the year 1790 he was elected secretory to the corresponding board of the "Society for propagating Christian Knowledge in the Highlands and Islands of Scotland." He was likewise chaplain to the "Scottish Corporation," and both these institutions were much benefited by his zealous exertions in their behalf. In the year 1795, he published two volumes of sermons, and in 1798 he gave the world eight "Lectures on the Evidences of Christianity," being the completion of a plan begun by Mr. Fell. The work contains a popular and useful elucidation of the proofs in favour of the Christian religion, arising from its internal evidence, its beneficial influence, and the superior value of the information which it conveys with respect to futurity. During the latter years of his life, Dr. Hunter's condition suffered the severest shocks from the loss of three children, which, with other causses, contributed to render him unable to withstand the attacks of disease. He died at the Hot-Wells, Bristol, on the 27th of October 1822, in the 62d year of his age. Dr. Hunter was a man of learning: his writings are eloquent, and shew how well he had studied human nature. In the pulpit his manner was unaffected, solemn and impressive. He indulged his liberal and friendly heart in the exercise of hospitality, charity, and the pleasures of social intercourse, frequently beyond the limits which a regard to prudence and economy should have prescribed. He was the translator of "Letters of Euler to a German Prince, on different Subjects in Physics and Philosophy;" "The Studies of Nature by St. Pierre;" "Saurin's Sermons;" "Sonninis Travels." Miscellaneous pieces and sermons of his own have been published since his death, to which are prefixed Memoirs; from these the foregoing particulars have been taken. Dr. Hunter, about the year 1796 or 7, began "A History of London and its Environs," which came out in parts, and which has lately been finished by other editors. It makes two large quarto volumes.

HUNTER, a name given to a horse qualified to carry a person on a horse. To make the horse designed for this service, should be strong and well knit together, as the jockeys express it. Irregular or unequal shapes in these creatures are always a token of weakness. The inequalities in shape which flew a horse improper for the chase, are the having a large head and a small neck, a large leg and a small foot, and the like. The head of the hunter should, indeed, always be large, but the neck should also be thick and strong to support it. The head should be lean, the nostrils wide, and the wind-pipe straight.

The whole shape of a horse intended for a hunter should be this; the ears should be small, open, and pricked; or though they be somewhat long, yet if they stand up erect, and...
and bold, like those of a fox, it is a sign of toughness or hardness. The forehead should be long and broad, not flat; or, as it is usually termed, nacre-faced, but rising in the middle like that of a hare; the feather should be placed above the eye, the contrary being thought by some to threaten blindness. The eyes should be full, large and bright; the nostrils not only large, but looking red and fresh within; for an open and fresh nostril is always deemed a sign of a good wind. The mouth should be large, deep in the wicks, and hairy. The wind-pipe should be large, and appear straight when he bristles his head; far, on the contrary, it bends like a bow on his bridling, it is not formed for a free passage of the breath. This defect in a horse is expressed among the dealers by the phrase cock-throop'd. The head should be so set on to the neck, that a space may be felt between the neck and the chin; when there is no such space, the horse is said to be bull-necked, and this is not only a blemish in the beauty of the horse, but it also occasions his wind not to be so good. The crest should be strong, firm, and well riven; the neck should be strong and firm, not loose and pliant; the breast should be strong and broad; the ribs round like a barrel, the fillets large; the buttocks rather oval than broad; the ears clean, flat, and straight; and, finally, the mane and tail ought to be long and straight. Not long and bulky, the last being counted a mark of dulness. When a hunter is thus chosen, and has been taught such obedience, that he will readily answer to the rider's signals, both of the bridle and hand, the voice, the calf of the leg, and the spurs; that he knows how to make his way forward, and has gained a true temper of mouth, and a right placing of his head, and has learned to stop and to turn readily, if his age be sufficiently advanced, he is ready for the field. It is a rule with all staunch sportsmen, that no horse should be used in hunting till he is full five years old; some will hunt them at four, but the horse at this time is not come up to his true strength and courage, and will not only fail at every tough trial, but will be subject to strains and accidents of that kind, much more than if he were to be kept another year longer, when his strength would be more confirmed.

When the hunter is five years old, he may be put to graze from the middle of May till Bartholomew-tide; for the weather between these is so hot, that it will be very proper to spare him from work. At Bartholomew-tide the strength of the graze begins to be nipped by frosts and cold dews, so that it is apt to engender crudities in the horse, he should be taken up while his coat is yet smooth and sleek, and put into the stable. When he is first brought home, he should be put in some secure and lapis place, where he may evacuate his body by degrees, and be brought, not all at once, to warm keeping; the next night he may be flabled up. It is a general rule with many not to clothe and flable up their horses till two or three days after they are taken from graze, and others who put them in the stable after the first night, yet will not drefs and clothe them till three or four days afterward; but all this, except the keeping the horse one day in a large and cool place, is needle's caution. There is a general practice among the grooms, in many places, of giving their hunters wheat-graie as soon as they take them up from graze. They say they do this to take up their bellies; but there seems much reason to disapprove of this. The change is very violent, and the nature of the graie for heating and drying, that there seems great reason to fear that the affrangent nature of it would be prejudicial, more than is at first perceived. It is always found that the dung is hard after this food, and is voided with pain and difficulty, which is in general very wrong for this sort of horse. It is better, therefore, to avoid this graie feeding, and to depend upon moderate airing, warm clothing, and good old hay, and old corn, than to have recourse to any thing of this kind.

When the horse has evacuated all his graze, and has been properly fed, and the hooves had time to settle to his feet, he may be ridden abroad, and treated in this manner: the groom ought to visit him early in the morning, at five o'clock in the long days, and at six in the short ones; he must then clean out the stable, and feel the horse's neck, flank, and belly; to find the state of his health, if the flank feels soft and flabby, there is a necessity of good diet to harden it, otherwise any great exercise will occasion swellings and goutiness in the heels. After this examination, a handful or two of good old oats, well sifted, should be given him; this will make him have more inclination to water, and will also make the water fit better on his stomach than if he drank falling. After this he is to be tied up and drested. If in the doing of this he opens his mouth, as if he would bite, or attempts to kick at the person, it is a proof that the teeth of the curry-comb are too sharp, and must be filed blunter. If after this he continues the same tricks, it is through wantonness, and he should be corrected for it with the whip. The intent of currying being only to raise the dust, this is to be brushed off afterwards with a horse-tail nailed to a handle, or any other light brush. Then he is to be rubbed down with the brush, and dusted a second time; he should then be rubbed over with a wet band, and all the loose hairs, and whatever foulness there is, should be picked off. When this is done, and he is wiped dry as at first, a large saddled-cloth is to be put on, reaching down to the spurring-place; then the saddle is to be put on, and a cloth thrown over it, that he may not take cold; then rub down his legs, and pick his feet with an iron picker, and let the mane and tail be combed with a wet mane-comb. Lastly, it is a custom to spurt some beer into his mouth just before the leading him out of the stable. He should then be mounted, and walked a mile at least to some running water, and there watered; but he must only be suffered to take about half his water at one drinking.

It is a custom of many to gallop the horse at a violent rate as soon as he comes out of the water, but this is extremely wrong for many reasons. It endangers the breaking a horse's wind more than any other practice, and often has been the occasion of hurting very good horses. It uses them also to the disagreeable trick we find in many horses, of running away as soon as ever they come out of the water; and with some it makes them averse to drinking, so that they will rather endure thirst, and hurt themselves greatly by it, than bring on the violent exercise which they remember always follows it. The better way is to walk him a little after he is out of the water, then put him to a gentle gallop for a little while, and after this to bring him to the water again. This should be done three or four times, till he will not drink any more. If there is a billy place near the watering-place, it is always well to ride up to it; if otherwise, any place is to be chosen where there is free air and sun. That the creature may enjoy the benefit of this, he is not to be galloped, but walked about in this place an hour, and then taken home to the stable. The pleasure the horse himself takes in these airings, when well managed, is very evident, for he will gape, yawm, and shrug up his body; and in thefe, whenever he would stand still to fale, dunt, or listen to any noife, he is not to be hindered from it, but encouraged in every thing of this kind.

The advantages of these airings are very evident; they purify
purify the blood, teach the creature how to make his breathing agree with the roll of the motions of his body, and give him an appetite to his food, which hunters and racers, that are kept haled up, are otherwise very apt to lose. On returning from airing, the litter of the stable should be fresh, and by stirring this, and whiffing, he will be brought to stale. Then he is to be led to his stall, and tied up, and again carefully rubbed down; then he should be covered with a linen cloth next his body, and a canvas one over that, made to fit him, and reaching down to his legs. This, as the duke of Newcastle observes, is a custom which we learnt of the Turks, who are, of all people, the moft nice and careful of their horses. Over this covering there should be put a body-cloth of six or eight fraps; this keeps his belly in shape, and does not hurt him. This clothing will be sufficient while the weather is not very sharp, but in severe feasons, when the hair begins to ride and start in the uncovered parts, a woollen cloth is to be added, and this will always proveFully sufficient.

Different horses and different feasons make a variety of the degree of clothing necessary; but there always is an obvious rule to point out the neceffary changes, the roughness of the coat being a mark of the want of clothing, and the freedom from it a proof that the clothing is sufficient. Therefore, if at any time the hair is found to start, it is a notice that some farther clothing is to be added.

If the horfe sweat much in the night, it is a sign that he is over-fed, and wants exercise; this, therefore, is easily remedied. An hour or more after the horfe is come in from his airing, the groom should give him a whip of clean hay, making him eat it out of his hand; after this let the manger be well cleaned out, and a quartern of oats clean fitfed be given him. If he eats up this with an appetite, he should have more given him; but if he is flow and indifferent about it, he must have no more. The builncs is to give him enough, but not to cloy him with food.

If the horfe gets flesh too faft on this home feeding, he is not to be hindered to prevent it, but only his exercife increased; this will take down his flesh, and at the same time give him strength and wind. After the feeding in the morning is over, the flable is to be flut up, only leaving him a little hay on his litter. He need be no more looked at till one o'clock, and then only rubbed down, and left again till the time of his evening watering, which is four o'clock in the fummer, and three in the winter. When he has been watered, he must be kept out an hour or two, or more, if neceffary, and then taken home and rubbed as after the morning watering. Then he is to have a feed of corn at fix o'clock, and another at nine at night; and being then cleaned, and his litter put in order, and hay enough left for the night, he is to be left till morning. This is the direction for one day, and in this manner he is to be treated every day for a fortnight, at the end of which time his flesh will be so hardened, his wind so improved, and his mouth so quickened, and his gallop brought to fo good a frothe, that he will be fit to be put to moderate hunting. During the time that he is used to hunting, he must be ordered on his days of rest exactly as he is directed for the fortnight when he is in preparation; but as his exercife is now greatly increafed, he must be allowed a more strengthening food, mixing some old split beans at every feeding with his oats.

And if this is not found to be sufficient, the following bread must be given: let two pecks of old beans, and one peck of wheat be ground together, and made into an indifferently fine meal; then knead it into dough, with some warm water, and a good quantity of yeaf! let it lie a time that it may rise and fwell, which will make the bread the lighter; then make it into loaves of a peck each, and let it be baked in a flow oven, that it may be thoroughly done, without being burnt; when it is taken out of the oven, it must be fet, bottom upwards, to cool; when it is one day old, the crust is to be clipped off, and the crumb given him for food. When this bread is ready, he should have some of it at least once in the day, but it is not to be made the only food, but some feeds are to be of oats alone; some of oats and this bread, and some of oats and beans mixed together. The making a variety in this manner, being the beft of all methods of keeping up the appetite, which is often apt to fail.

The day before the horfe is to hunt, he must have no beans, because they are hard of digeffion, but only some oats with this bread; or if he will be brought to eat the bread alone, that will be beft of all. His evening feed should, on this day, be somewhat earlier than usual; and after this, he is only to have a whip of hay out of the groom's hand till he return from hunting.

The hunter, in order to his behaving well in the feafon, ought to take very good care and indulgence in the stable; he ought to have as much rest and quiet as may be, to be kept well supplied with good meat, clean litter, and fresh water by him; he should be often drofled, and fuffered to feed as much as he pleafes. He should be fowed that his dung may be rather foft than hard, and it muft be of a bright and clean colour. All this may be eafily managed by the continual obfervance and change of his food, as occasion requires. After his usual flourings he should have exercifes and malties of sweet milk, or bread and beans; or wheat and beans mixed together, are to be his belt food, and beans and oats his work.

Some very great fportsmen are for keeping their horses out of grafs all the buck-hunting feafon, never taking them up into the stable at all, but allowing them in the field as much oats with their grafs as they will eat. The horfe may be thus rid three days in the week for the whole feafon, and never damaged by it, nor ever showing any marks of harm afterwards.

HUNTER'S DAY, or Rigg day, in Geography, a bay of Scotland, on the E. coast of the county of Wigtown.

HUNTER'S TOWN, a town, or village, of Pennsylvania, situated in York county; 25 miles W. by S. of York town.

HUNTERDON, a county of New Jersey, in America, bounded N. by that of Morris, E. by Somerset, S.E. by Burlington, S.W. and W. by Delaware river, which separates it from the state of Pennsylvania, and N.W. by Suffolk county; about 40 miles long and 32 broad, divided into 12 townships, containing 22,641 inhabitants, including 1320 farmers. On Mountcong mountain in this county, is a strong chalybeate spring, to which many persons resort; it flows from the side of an eminence into an artificial resvoir, for the accommodation of those who wish to bathe in, as well as to drink, the waters. The chief town of the county is Trenton.

HUNTING, the art, or act, of pursurfng and chafing beafs of game. See GAME.

In its general leafe, hunting includes the pursurf both of hairy and feathered game; but in its more proper and refeained signification, it is only applicable to beafs of venery and chafe.

P. De Launay, formerly professor of the French laws, has an express treatife of hunting.

The antiquity of hunting may be traced back upwards of 2000
Hunting.

2600 years before the Christian era. The sacred history 
describes the first warriors under the name of hunters. 

This Nimrod is represented as "a mighty hunter before the 

Lord." (Gen. x. 9.) In the sequel, he made followers of 

his companions, who had assisted him in hunting and 

destroying the savage beasts that laid waste the country about Babylonia, and employed them in extending and establishing his con-

quests.

"Bold Nimrod first the lion's trophies wore, 
The panther bound, and lanc'd the briling boar: 
He taught to turn the hare, to bay the deer, 
And wheel the courier in his mid career." Tickell.

We find, that among the more civilized nations, as the 

Periains, Greeks, and Romans, it always made one of their 
gentleman diversions; and as to the wilder and more bar-

barous, it served them with food and necessaries. The Roman 

courtly, which was formed on the manners of the first 

ages, made a law of it, and established it as a maxim, that 
as the natural right of things which have no master belongs 
to the first possessor; wild beasts, birds, and fish, are the 

property of him, whoever be he, that can first take them. 

But the northern nations of barbarians, who over-ran the 

Roman empire, bringing with them a stronger taste for the 
diversion, and the people being now possess'd of other, and 

more easy means of subsistence from the lands and posses-
sions of those they had vanquish'd; their chiefs and leaders 

began to appropriate the right of hunting, and, instead of a 
natural right, to make it a royal one. Thus it continues to 

day, the right of hunting, among us, belonging only to 

the king, and those who derive it from him.

And hence have arisen all our laws and charters of the 

forests, laws and regulations for preservation of the game, 

&c. See Forest, Game, and Trespass.

The hunting used by the ancients was much like that now 

practised for the rein-deer; which is seldom hunted at force, 
or with hounds; but only drawn with a blood-hound, and 

forestaled with nets and engines. Thus did they with all 

beasts; whereas a dog is never commence'd by them for 

opening, before he has discover'd where the beast lies: 
hence they were not in any manner curious as to the music 
of their hounds, or the composition of their kennel or pack, 
either for deepness, loudness, or sweetness of cry, which is 

become a principal point in the hunting of our days.

Their huntsmen, indeed, were accustomed to shout and 

make a great noise, as Virgil observes in the third of his 

Georgics: "ingenia clamore premes ad retia cervum."

But that clamour was only to bring the deer to the nets 
laid for him.

The Sicilian way of hunting had something in it very 

extraordinary. The nobles or gentlemen being informed which 

way a herd of deer passed, gave notice to one another, and 

appointed a meeting; every one bringing with him a cross-

bow or long-bow, and a bundle of arrows, shot with iron, 

the heads bored, with a cord passing through them all: 

thus provided they came to the herd, and calling themselves 

about in a large ring, surrounded the deer. Then, each 

taking his fand, unbound his faggot, set up his flake, and 
tied the end of his cord to that of his next neighbour, at 

the distance of ten feet from one another. Then taking 

feathers dyed in crimson, and fastened on a thread, they tied 

them to the cord; so that with the leaf-breath of wind 

they would whirl round. Which done, the persons who 

kept the fands withdrew, and hid themselves in the next 

covert. Then the chief ranger entering within the line with 

hounds to draw after the herd, routed the game with their 

cry; which flying towards the line, were turned off, and 

still gazing on the flaking and humming feathers, wandered 

about as if kept in with a real wall or pale. The ranger 

still pursued, and calling every perfon by name, as he passed 

by their land, commanded them to shoot the first, third, or 

sixth, as he pleased; and if any of them missed, or fangled 

out another than that affign'd him, it was counted a grievous 
disgrace. By such means, as they passed by their several 

stations, the whole herd was killed by the several bands.

Hunting constituted a great part of the employment of the ancient Germans and also of the Britons, when the 

more furious occupations of war did not engage their atten-
tion. This was not merely an amusement to which, in 

many cafes, the ferocity of their temper actually inclined 

them, but it was the principal means by which, in the uncult-

ivated state of the countries which they inhabited, they 

procured their subsistence. Such was the case so late as the 
third century with those unconquered Britons who 

lived beyond Adrian's wall. With the Celtic nations 
hunting, to which they were inordinately attached, served as 
a preparatory discipline to war; and it has answered the 

same purpose in many other nations, which we have been 

accustomed to denominate barbarous. So general and so 

ardent was the attachment to hunting among the ancient 

Britons, that, whilst the chieftains practis'd it in order to 

propofe their mistreses with a favourable opinion of their 

valour and agility, young ladies of distinguished rank and 

beauty devoted much of their time to the chase. On ac-

count of the general prevalence of this pastime, and its 

apprehended injury to the general interests of society, the 

liberty of the chase has been more or less restrained from 

early ages, and kings and princes have successively augmented 

their afluenced rights in hunting; claiming to themselves the 

primitive and sole title to hunt, and controlling their no-

bles, and all persons of inferior rank, from enjoying this 

amusement, unless, as we have before observed, the privi-

lege was granted by them, and liable to be revoked at 

their will. Hence arose the numerous and severe restraints 

and penalties of the game laws. See Game.

Among the Mexicans hunting was a favourite exercise; 

and in pursuing it they used, with singular dexterity, bows 

and arrows, darts, nets, snares, and a kind of tubes, through 

which they shot out, by blowing, little balls at birds. 

Those instruments, of this kind, that were used by their kings 

and great men, were curiously carved and painted, and 

adorned with silver and gold. Besides their private hunting 

exercises, in which they engaged for amusement or sub-

sistence, they had also hunting matches, either appointed by 

the king, or undertaken with a view of providing victims for 

their sacrifices. A wood, not far from the capital, was 

selected for this purpose; and it was enclosed by some 

thousands of hunters, who formed a circle of six, seven, or 

eight miles, according to the number of animals which they 

proposed to take. There was then fed to the game in a num-

ber of places, and a terrible noise was made with drums, 

horns, hooting and whistling. The hunters at the same 

time gradually contracted their circle, and thus enclosed the 

game in a very small space, and it was taken in the snares 

that had been previously fet, or killed by the hunters. The 

number of animals, comprehending deer, wild goats, hares, 
rabbits, &c. collected and destroyed on these occasions, is 

almost incredible.

Hunting was also much practised by the savage and 

bloody conqueror Genghis-Khan; and his method of em-

ploying his fohners in a kind of warfare with the beasts, 

when they had no human enemies with whom to contend, 

was similar to that of the Mexicans. The chase is still an 

object to which the East Indian princes are much inclined.

Mr.
Mr. Blane, who attended the hunting excursions of Afophul Donougher, ruler of the Mogul empire, and nabob of Oude in 1785 and 1786, gives the following account of them.

The time chosen for the hunting party is about the beginning of December; and the diversion is continued till the heat, which commences about the beginning of March, oblige them to stop. During this time a circuit of between 460 and 600 miles is generally made; the hunters bending their course towards the flanks of the northern mountains, where the country is wild and uncultivated. The vihir takes along with him not only his court and retinue, but a great part of the inhabitants of his capital. His immediate attendants may amount to about 3000; but besides these he is also followed by 500 or 600 horses, and several battalions of regular fappers with their field-pieces. Four or five hundred elephants are also taken along with him: of which some are used for riding, others for fighting, and some for clearing the jungles and forests of the game. About as manyumper horses of the beautiful Persian and Arabian breeds also accompany him. A great many wheel carriages drawn by bullocks likewise attend, which are used chiefly for the convenience of the women; sometimes also he has an English chaise or two, and sometimes a chariot; but all these, as well as the horces, are merely for show, the vihir himself never using any other conveyance than an elephant, or sometimes, when fatigued or indisposed, a palanquin.

The animals used in the sport are principally gré-hounds, of which there may be about 300; he has also about 300 hawks, and a few trained leopards for hunting deer. There are a great number of markshins, whole profession it is to shoot deer; with many fowlers, who provide game; as none of the natives of India know how to shoot game with small shot, or to hunt with flow hounds. A vast number of matchlocks are carried along with the company with many English pieces of various kinds, 40 or 50 pairs of pistols, bows and arrows, besides swords, daggers, and sabres without number. There are also nerts of various kinds, some for quail, and others very large, for fishing, which are carried along with him upon elephants, attended by fishermen, so as always to be ready for throwing into any river or lake that may be met with. Every article that can contribute to luxury or pleasure is likewise carried along with the army. A great many carts are loaded with the Ganges water, and even ice is transported for cooling the drink. The fruits of the season and fresh vegetables are daily sent to him from his gardens by bearers flatted or at distances of every ten miles; by which means each article is conveyed day or night at the rate of four miles an hour.

Beside the animals already mentioned, there are also fighting antelopes, buffaloes; and rams in great numbers; also several hundred pigeons, some fighting cocks, with a vast variety of parrots, nightingales, &c.

To complete the magnificence or extravagance of this expedition, there is always a large bazaar, or moving town, which attends the camp; consisting of shop-keepers and artificers of all kinds, money-changers, dancing-women; so that, on the most moderate calculation, the whole number of people in his camp cannot be computed at fewer than 20,000. The nabob himself, and all the gentlemen of his camp, are provided with double sets of tents and equipage, which are always sent on the day before to the place to which he intends to go; and this is generally eight or ten miles in whatever direction most game is expected; so that by the time he has finished his sport in the morning, he finds his whole camp ready pitched for his reception.

The nabob, with the attending gentlemen, proceed in a regular moving court or durbar, and thus they keep con

verging together and looking out for game. A great many foxes, hares, jackals, and sometimes deer, are picked up by the hawks along: the hawks are carried immediately before the elephants, and let fly at whatever game is sprung for them, which is generally partridges, buf tarns, quails, and different kinds of herons; these last affording excellent sport with the falcon's or sharp-winged hawks. Wild boars are sometimes started, and either shot or run down by the dogs and horsemens. Hunting the tyger, however, is looked upon as the principal diversion, and the discovery of one of these animals is accounted a matter of great joy. The cover in which the tyger is found is commonly long grafs, or reeds of such an height as frequently to reach above the elephants; and it is difficult to find him in such a place, as he commonly endevours either to steal off, or lies so close to the ground that he cannot be routed till the elephants arc almost upon him. He then roars and fells away, but is not at ftoon as he can be fen; it being generally contrivened that the nabob fhall have the compliment of firing firi. If he be not disabled, the tyger continues to fwell along, followed by the line of elephants; the nabob and others flowing at him as often as he can be fen till he falls. The elephants themselves are very much afraid of this terrible animal, and discover their apprehenfions by shrieking and roaring as soon as they begin to smell him or hear him growl; generally attempting to turn away from the place where he is. When the tyger can be traced to a particular spot, the elephants are dispoited in a circle round him; in which cafe he will at lift make a desperate attack, springing upon the elephant that is nearest, and attempting to tear him with his teeth or claws. Some, but very few, of the elephants, can be brought to attack the tyger; and this they do by curling up their trunks under their mouths, and then attempting to tofs, or otherwise destroy him with their tusks, or to crush him with their feet or knees. It is con

fidered as good sport to kill one tyger in a day; though sometimes, when a female is met with her young ones, two or three will be killed.

The other objects of purtife in these excursions are wild elephants, bufaloes, and rhinoceroses. Our author was prent at the hunting of a wild elephant of vaft size and strength. An attempt was first made to take him alive by surrounding him with tame elephants, while he was kept at bay by crackers and other fire-works; but he continually eluded every effort of this kind. Sometimes the drivers of the tame elephants got near him, that they threw strong ropes over his head, and endeavoured to detain him by fastening them around trees; but he wholly flapped the ropes like pack-threads, and pursed his way to the forest.

Some of the strongest and most furious of the fighting elephants were then brought up to engage him; but he attacked them with such fury that they were all obliged to defert. In his struggle with one of them he broke one of his tusks, and the broken piece, which was upwards of two inches in diameter, of solid ivory, flew up into the air several yards above their heads. Orders were now given to kill him, as it ap

peared impossible to take him alive; but even this was not accomplished without the greatest difficulty. He twice turned and attacked the party who pursued him; and in one of these attacks struck the elephant obliquely on which the prince rode, threw him upon his fide, but then passed on without offering further injury. At laft he fell dead, after having received, as was conjectured, upwards of 1000 balls into his body. See ELEPH.

Hunting, considered as an exercife, is perhaps the beft that can poibley be contrived for strengthening the general habit, and procuring health and vigour. The leafon of the year, the
the time of the day defined for this amusement, and the motion necessary on this occasion, are all admirably adapted to the restoration and continuance of health. It is, besides, of no small importance to have the mind recreated at the time the body is exercised; for this admirably affords the due circulation of the fluids through the minute canals defined for their conveyance; and there are few people not utterly abandoned to idleness and debauchery of some kind or other, who do not perceive a spontaneous flow of spirits when they ride at or about the rise of the sun, when they respire the purest air, with variety of perpetually changing scenes present themselves, and when the mind is agreeably agitated concerning the event of the chase.

If we advert to the character of those nations in ancient times, which were most addicted to this exercis, we shall find that they delighted in war, and in oppressing and enslaving their own species. Nimrod, the mighty hunter, was a tyrant. The Lacedaemonians indulged themselves without controul in this exercis, whilst they cruelly oppressed those whom they had in their power. (See Hillots.) The wise legislator Solon restrained the Athenians from gratifying themselves in this way, lest they should be led to neglect the mechanic arts. The Egyptians, Persians, and Scythians, &c., were fond of hunting and of war. As mankind became more civilized, hunting became less prevalent: such was in a degree the case with the Romans, although they continued to a late period to make death and slaughter familiar to the citizens, by the diversions of the amphitheatre and circus, which consisted of exhibitions of wild beasts, and of human gladiators, destroying one another. Those who think the exercis of hunting incompatible with the principles of humanity, allege that it is allowable only when an uncultivated country is over-run with noxious animals, or when it is necessary to kill wild animals for food. For a defence of this diversions, and an attempt to reconcile it with the sentiments and feelings of humanity, see Manchester Transactions, vol. 1. p. 241, &c.

Hunting is practised in a different manner, and with a different apparatus, according to the nature, genius, and address, of the particular beast which is the object of it. These beasts are, the hart, hind, hare, bear, wolf, buck, doe, fox, martens, and rac; the five first of which are denominated beasts of the forest, or vixens, stygirist; and the five latter, beasts of the field, or chase, campfeller.

The gentlemen, and masters of the sport, have framed a new list of terms, which may be called the hunting language—a concise vocabulary of which we shall here give the reader.

The terms, then, used for beasts of venery and chase, as they are in company, are the following: They say, a herd of harts, and all manner of deer; a bay of roes; a fender of swine; a rout of wolves; a riches of martens; a brace or lead of bucks, foxes, or hares; a couple of rabbits or conies. There are also terms for their lodging; a hart is said to barrow; a buck lodges; a doe beds; a hare feats, or forms; a coney fits; a fox banks; a martens trees; an otter watches; a badger marts; a boar coosers. Hence, to express their dislodging, they say, unhbarrow the hart; roose the buck; flar the hare; bolt the coney; unkenkel the fox; unmar the martens; venet the otter; dig the badger; rear the boar.

The terms for their noize at rutting time are as follows: A hart belleth; a buck greets or prods; a doe bellows; a hare beats or taps; an otter whines; a boar screams; a fox barks; a badger braits; a wolf howls; a goat rattles.

Terms for their copulation; a hart or buck goes to rut; a doe goes to towm; a bear goes to brim; a hare or coney goes to buck; a fox goes to cliking; a wolf goes to mathe or maketh; an otter hunteth for his kind.

Terms for the footing and treading; of a hart we say, the flet; of a buck, and all fallow deer, the goane; of all deer, if on the grass, and fierce visible, the footing; of a fox, the print; and of other the like vermin, the footing; of an otter, the marks; of a boar, the track; the hare, when in open fields, is said to fors; when the wind is about to deceive the hounds, the doublet; when the feet on the hard highway, and her footing comes to be perceived, the prioketh; in snow, it is called the trace of the hare.

The tail of a hart, buck, or other deer, is called the single; that of a boar, the wraith; of a fox, the bruis or drag; and the tip at the end, the chape; of a wolf, the stote; of a hare and coney, the fest.

The ordure or excrement of a hart, and all deer, is called the foame or fecesmiftings; of a hare, creoles or croshing; of a boar, lefes; of a fox, the biling; and of other the like vermin, the jumps; of an otter the spesiat.

As to the heads of deer, something has already been spoken under the article HEAD.

For the attire or parts thereof, those of a flag, if perfect, are, the bar, the pallet, the little knote on it, the bean, the winit, the antler, the tamar, the royal, the grass, and all at top, the croches; of the buck, the bar, the bean, brow-antler, back-antler, advance, palm, and spellers.

If the croches grow in the form of a man's hand, it is called a pandem head. Heads bearing not above three or four, and the croches placed aloft, all of one height, are called crowned beads. Heads having double croches, are called forked beads, because the croches are planted on the top of the like forks.

They lay a litter of cubs; a styff of rabbits; a squirrel's dry.

The terms used in respect to the dogs, &c., are as follows: Of grey-hounds, two make a brace; of hounds, a couple; of grey-hounds, three make a kent; of hounds, a couple and half—that they say, let slip a greyhound; and call off a hound; the flying wherein a grey-hound is led is called a kent; and that of a hound a kynoe; the grey-hound has his collar, and the hound his kynoes: we say a hound of hounds, and a pack of beagles.

Hunting, styles or manners of, are various, according to the country, the beast, and the means whereby he is to be caught.

Hunting, as practised among us, is chiefly performed with dogs; of which we have various kinds. Accommodated to the various kinds of game: hounds, grey-hounds, foambounds, blood-hounds, terriers, &c. See Dog, Hound, &c.

In the kennels or packs, they generally rank them under the heads of enteriers, drivers, flyers, stubs, &c.

On some occasions, nets, sippets, and instruments for digging the ground are also required; nor is the hunting-horn to be omitted. See Horn.

The usual chases among us are, the hart, buck, roe, hare, fox, beagles, and terriers. We shall here give something of what relates to each of these.

With regard to the feasons of hunting; hart and buck hunting begins at the end of fence-month, which is a fortnight after Midsummer, and lasts till Holy-rood-day. The hound and doe come in course on Holy-rood-day, and last till Candlemas. Fox hunting comes in at Christmas and holds till Annunciation.

Boar hunting begins at Michaelmas and ends at Candlemas. Hare hunting commences at Michaelmas, and goes out at the end of February. Where the wolf and bear are hunted, the feason for each begins at Christmas; the first
HUNTING.

ending at the Annunciation, the second at the Purification.

Here, too, is the place for some general terms and
phrases, more immediately used in the progress of the sport
itself; what belongs to the several sorts of game in particu-
lar, being referred for the respective articles.

When the hounds, then, being cast off, and finding the scent
of some game, begin to open and cry, they are said to chal-
cenge; when they are too busy before the scent is good,
they are said to babbles; when too busy where the scent is
good, baw; when they run it endsways orderly, holding in
together merrily, and making it good, they are said to be in
full cry; when they run along without opening at all, it is
called running mute.

When spaniels open in the string, or a grey-hound in the
cours, they are said to lopes.

When beagles bark and cry at their prey, they are said
to year.

When the dogs hit the scent the contrary way, they are
said to draw amifs.

When then they take fresh scent, and quit the former
cours for a new one, it is called hunting change.

When they hunt the game by the heel or track, they are
said to hunt counter.

When the cours goes off, and returns again, traversing
the same ground, is it called hunting the field.

When the dogs run at a whole herd of deer instead of a
single one, it is called running riot.

Dogs set in readiness where the game is expected to come
by and call off after the other hounds are palled, are called
delay.

If they be call off before the other dogs be come
up, it is called a countrey.

When, finding where the cours has been, they make a
proffer to enter, but return, it is called a blemiff.

A lesson on the horn to encourage the hounds is named a
call or recheat. That blown at the death of a deer is called
the mort. The part belonging to the dogs of any cours
they have killed is the reward. They say, take off a deer's
skin, slip or cafe a hare, fox, and all sorts of venin; which
is done by beginning at the front, and turning the skin over
the ears down to the tail.

HUNTING, Laws relating to. See GAME.

Notwithstanding all the game laws, and the various qua-
lifications for hunting pointed out by statutes, which imply
a power for enforcing so qualified to hunt yet, according to judge
Blackstone, no man but he who has a chief, or free-warren,
by grant of the crown or prescriptive, which supposes one,
can justify hunting or sporting upon another man’s soil; nor
indeed, in thorough titheowners of common law, either hunting
or sporting at all. By flat. 1 Hen. VII. c. 7. unlawful
hunting in any legal forest, park, or warren, not being the
king's property, by night, or with painted faces, was declared to
be sngle felony. But now by the statute 9 Geo. I. c. 22.
to appear armed in any enclosed forest or park where deer are
usually kept, or in any warren for hares or conies, or in any
high road, open heath, common, or down, by day or night, with
faces blacked or otherwise dignified, or (being so dignified)
to hunt, wound, kill, or deal any deer, to rob a warren, or
to steal fish, or to procure by gift or promise of reward any
perfon to join them in such unlawful act, is felony without
benefit of clergy. Perfofs so hunting are liable to actions of
trepass by the offefors of the land. Comment. vol. ii.

HUNTING, Badger. A badger is called by several names
viz., a grey, bock, bourseon, or bourfon: the male is called a
badger, or boar-pig, and the female a sow. See USUFS
Milk.

This beast is very frequent in Italy, Sicily, the Alpines,
and Helvetic countries; and is not uncommon in France and
England. It is found also as far north as Norway and
Ruffia; in Siberia, about the rivers Tom and Lena; it in-
habits China, and is exposed to fale for food in the markets of
Pekin.

The badger is a very sleepy beast, especially in the day-
time, seldom stirring abroad but in the night; whence the
denomination lythert, d. avoider of the light. It burrows
under ground like the fox, and forms several different apart-
ments, though with only one entrance, carrying in its
mouth grafs in order to form a bed for its young. It is so cleanly
an animal, that it never obeys the call of nature in its apart-
ments, but goes out for that purpose. It breeds only once
in a year, and brings four or five at a time.

The badger is a deep biting beast, having very sharp teeth;
to guard against the effects of which, it is usual to put great
broads collars about the dogs' necks. He fights on his back,
and by this means is at liberty to use both his teeth and nails.
He has a faculty of blowing up his skin after a strange man-
er, by which he defends himself against any blow or bite of
the dogs; so that you may thrani on his back till you are
weary to no purpose: but a small stroke on the nose dis-
paches him presently. The skin of the badger, when
tidied with the hair, is used for pistol furniture. The High-
lakers make their pendant pouches of it. The hair is often
used for making brushes to soften the shades in painting,
called sweetening tools. These animals are also hunted in
the winter nights for the sake of their flesh, for the hind quar-
ters may be made into hams, not inferior in goodness to the
belt bacon. The fat is much valued for ointments and

The method of hunting the badger is thus: seek the
earth and burrows where he lies, and in a clear moonshine
night go and tlop all the holes but one or two, and therein
place faucets, fastened with drawing strings, which may shut
him in as soon as he strains the bag. The bags thus fet, call
off your hounds, and beat all the groves, hedges or tusks in
a mile or two: the badgers that are abroad being alarmed
by the dogs, will straight repair to their earths, and soon be
taken. He that lays to watch the facks must stand close,
and upon a clear wind, and he the badger will find him, and
fly some other way for safety. If the hounds either encoun-
ter him, or undertake the cours before he can get into his
earth, he will land at bay like a boar, and make excellent
sport.

If the badger be attacked in his earth, as soon as he per-
ceives the terriers yarrow him, he will top the hole between
the dogs and himself; and if the dogs continue baying, he
removes his baggage with him, and goes into another apart-
ment or chamber, of which he usually has half a dozen in
the burrow; thus retreating from one to the other, till he
can go no farther, and barricading the way as he goes.
In hunting the badger as well as the fox, a man cannot judi-
fily breaking the foul, and digging him out of his earth.

Another mode of catching badgers is by a "pit-fall"
across their accustomed path. This should be five feet deep
and four feet long, narrow at the top and bottom, and wide
in the middle. This pit must be covered with small boughs or
flicks, which retain their leaves (either withered or green,
according to the season) they must be so laid, that the
weight of the badger when he treads upon them will instantly
make them give way. The digging of badgers is, without
very good terriers, a work of time; for if terriers do not keep
countably at him, from his facility in penetrating and throw-
ing back the earth (which he poises beyond any other ani-
mal) he will, in loose sand, bury himself faster than the
workmen.
workmen can sink pits, by which he may be got into an angle.

Hunting, Boar. See Boar.

Hunting, Buck, or hunting fallow deer. See Buck, and Cervus Dama.

The female is called doe, or does: the first year a fawn; second, a tegg; the third, a doe. See Deer.

Let's art and skill are required in lodging a buck, than in harvesting a hart or stag; nor does there need so much drawing after; it is sufficient that you judge by the view, and mark what grove or covert he enters; for he does not wander and rove so often as a hart, nor so frequently change his layer. When hard hunted he usually takes to some strong hold or covert, with which he is acquainted; not flying far before the hounds, nor crossing nor doubling, nor using any of the subtleties the hart is accustomed to.

The buck will beat a brook, but seldom a great river as the hart, nor can he fly so long at a time.

The greatest fatuity a huntman need use in hunting the buck, is to beware of hunting counter or change, because of the plenty of fallow deer, which use to come directly upon the hounds than the red deer do.

The buck herds more than the hart, and lieth in the driest places; but if he be at large, unconfined in a park, he herds but little from May to August, because the flies trouble him. He takes delight in hilly places, but chooses the dales to feed in.

Hunting, Fox. See Fox. His nature, in many respects, is like that of a wolf; and both bring the same number of cubs at a litter: but the fox litters deep under ground, which the wolf does not.

The fox sleeps much and found during the day, and, like the dog, lies in a round form, and may be approached without waking him; but he is in motion and seeking his prey the whole night. When only repelling himself he stretches out his hind legs, and lies on his belly: in this position he spies the birds, as they alight near him, and is ready to spring upon such as are within his reach. Crows, magpies, and other birds, which consider the fox as a common enemy, have such an antipathy to him, that they often give notice of his retreat, by the most clamorous noises. Jays and blackbirds, in particular, will incessantly repeat the watch cries; and when the hounds are in chase of him, crows and magpies will follow him with their screams from tree to tree to a considerate distance, and not unfrequently, when hounds are at a check, indicate which way the fox has shaped his course. The fox has proverbially a strong and offensive smell; he has also a yelping kind of bark, which consists of a quick succession of similar tones, at the end of which he generally rallies his voice, like the cry of the peacock. In winter, and especially during frost and snow, and when going to catch, he yelps much; but in summer he is almost entirely silent; and during this season he calls his hair.

A bitch fox is hard to take when breeding and with cub, in regard the lies near her burrow, into which the runs upon hearing the bait noise: indeed it is so easy matter to take her at any time, as being a beast of exceeding fidelity. After littering, if she perceives her retreat is discovered, she carries off her cubs, one by one, to a more secure situation.

What makes fox-hunting the more entertaining, is the strong hot scent this creature affords, which keeps up an excellent cry; but as his scent is hotter at hand, so it dies sooner than that of a hare, &c. Add, that he never flies far before the hounds, as not troubling to his legs or the chapman ground, but has recourse to the strongest coverts. When he can no longer stand up before the hounds, he takes earth, and must be dug out. When coursed by grey-hounds, on a plain, his last refuge is usually to pits on his tail, and slap it in their faces as they come near him; sometimes squirting all his thicker excrement upon them, to make them give over their course.

When a bitch fox goes a clicketing, and seeks the dog, the cries with a hollow voice, not unlike the howling of a mad dog; and the like noise she makes when she miffes any of her cubs; but the never cries at all when she is about to be killed, but defends herself in silence to the last gap.

The fox is taken with hounds, grey-hounds, terriers, nets, and gins. Of terriers there are two sorts: the one crook-legged, and commonly short-haired, which take earth well, and lie long at fox or badger; the other is shagged, and straight-legged, which will not only hunt above ground as others, but also enter the earth with great fury, though these cannot stay in so long on account of their vehemence.

The fox takes to earth in ground hard to dig: as in clay or flinty ground, or among the roots of trees; and his earth is commonly but one hole, which goes straight along in, before it comes to their couch; he sometimes by craft puffs himself of a badger's old burrow, which has variety of chambers, holes, and angles. Géfener relates, that he frequently cheats the badger of his habitation, by laying his excrement at the mouth of the other's burrow.

The modes of hunting the fox formerly, and that practised at present, are very different. In the earliest days, when this country was far more woody, and foxes so much abounded, as to be in a degree like wolves a general nuisance, what was then termed fox-hunting was effected by a great number of people, with dogs of all kinds, who assembled at the coverts where the foxes harboured. And whilst some beat the place, others went into the woods with some of the dogs and forced them out, to be either coursed by the rest of the dogs, which were held ready to be flipped at them, or they were, taken in nets and hays let on the outside for that purpose.

As the covers were reduced in size and number, this system of self-defence against the fox's depredations, gave rise to the chase as an object of amusement; the reason for hunting them began in November and ended in March, as in the cold weather the fox was fapposed to leave a stronger scent; the earths were dropped in the course of the night before hunting, (which is perhaps the only point in which the fox-hunting of the former and present time concurs,) a huntman was appointed, whose business was to take all his dogs in couples and bariled, early the following morning to the wood, designed to be tried, there to throw off his fire finders or leauch hounds, that would undertake no other feint, but that of the fox; if they struck upon a drag, he calls off more of his bell hounds, and so continued to do until they ran the drag up to the fox's kennel, which was the most opportune moment to throw off the major part of the coupled hounds; the fox, finding himself thus hotly purfued, after trying to hunt the hounds, was compelled to forsake the cover and trawl to his feet, fleeing from wood to wood, and sometimes extending his course for twenty miles; the huntman on foot was to crofs (with what hounds he had in reserve) the nearest cut from cover to cover, and to be as much as possible in the way to throw off those fresh hounds, either as an encouragement to the finders or leauch hounds that might begin to run lag, and which he was also to encourage by all possible means, or he was to keep back this corps de reserve, to have them, as occasion might offer, ready for a dead scent, or, as he judged prudent, for the latter end of the day. When the fox was killed the pack was to be hallowed in to bay him, but they were not allowed to eat
HUNTING.

him, because his flesh was harmful to them; his fat was however in high esteem for shrunk limes.

If the fox ran to ground, the huntsman, who was to be provided with good terriers, was to lay him up in the earth, which, in the opinion of some, was sooner done by putting a collar of bell on the terrier, that when dug out, he was sometimes given to the bounds to be killed on the earth as an encouragement, and also to make them lie when they came to a strange wood and to an unknown earth, at other times he was merely alive for a future day's sport; if the earth proved so deep that it was impossible to dig him out, fleal-traps were set at the mouth of the hole, or hay nets pitched round it, to take him at his going off, and these implements were to be carefully watched.

The whole art of fox-hunting, says Daniel in his "Rural Sports," is to keep hounds (see HOUND) well in blood, and therefore every advantage is taken of the fox. Sport is a secondary consideration with a true fox-hunter; his first motive is the killing of the fox, by which he makes his bounds profit. Success is almost a sure fore-runner of future sport, and he is better pleased with an indifferent chase with death at the close of it, than with the bell chase possible, if it terminates with the loss of the fox. Good chases are, generally speaking, long ones, and if unsuccessful, do more harm than good to hounds. It will be an advantage to bounds when out of blood to go out early. The morning is the part of the day which usually affords the bell scent, and the animal itself, which you are at this time more than ever desirous of killing, is then least able to escape; the want of scent, added perhaps to a full belly, gives hounds a decided superiority over an early-found fox. Hounds should never be taken out in a very windy or bad day, because scent is at such times extremely precarious. (See SCENT.)

Two things, says Mr. Daniel (obi supra), are ever to be remembered and accomplished in fox-hunting; the one is, to make bounds steady, the other to teach and compel them all to draw: yet never suffer any bounds out of cover, it is the effect of bad management if they attempt to be so; bounds once become steady will be more likely to draw well than if they were not, their eagerness is then to find their proper game, and they are indifferent to the scent or view of any other. Many huntsmen are fond of having hounds at their hounds' heels, and it is a modern fashion for the huntsman and whippers-in to ride into the cover, and by their noise, in some measure, to find the fox for their hounds; but this proceeding invariably renders hounds bad drawers, independent of the great chance of rubbing the horses, which in an inclosed country too often occurs, without needlessly courting the danger; it is liable also, where there are but few finders, to have a fox found by them, which goes down the wind, and they are heard of no more that day; besides, hounds never get so well or so keen together as when they spread the cover.

There is infinite pleasure, says a sportsman, in hearing when a fox is well found, the chorus increasing from the first challenge, and the corresponding "Hark to Chipper" inspires a joy more easy to be felt than described; and one fox found with a good draw in this lively manner, surpasses the bell hare chase that was ever ran.

Much a dog depends on the first finding a fox, who, if well found, may be laid to be half killed. The huntsman should draw quietly, and by the wind; this is material; the fox, by drawing up the wind, does not hear the approach of the hounds, who by this means are also within hearing; besides, should the fox turn down the wind, as most probably he will, it lets the hounds all in. If covers are small, and from which a fox cannot break unseen, noise can then do no hurt, but late in the season foxes are wild, particularly in covers that are often hunted, and should there be any noise, they will shrink their kennels and get too much advantage; the whippers-in, in whose duty it is inspected to happen, should get on the wind at the opposite side of the cover, before the hounds are thrown into it.

Judicious huntsmen will observe where foxes like bell to lie; this must of course vary in different countries, and a knowledge of the country will direct them in this respect. Where there are large tracts of cover, such observation will give time in finding; generally speaking, foxes prefer covers that lie high, are dry and thick at bottom, that are out of the wind, and are on the funny side of hills. The cover where a fox is found, when it has remained still any time, will probably produce a second. In nutting time, furze brakes and two or three years coppices are then the only quiet places for a fox to kennel in; when pleasanter footing begins, older covers are more likely. The fenon when foxes are most wild and strong is near Chirk-brown; a huntsman must at that season lose no time in drawing, and he as silent as possible; three or four years coppices, with beech or furze at bottom, are then most likely. The male foxes, about Christmas, travel miles after the females, and when hunted, generally run directly for the country from whence they came; the huntsman has at that season, in the course of three weeks, killed two brace of dog foxes from one cover, where the leaf distance was twelve, and in one of the four chases was extended to double the number of miles, from the place of un kennelling, to the spot where the fox was killed.

When a string of small covers have plenty of foxes in them, some caution is necessary to prevent them being all disturbed in one day. Foxes are said to go down wind to their kennel, but however that may be, the huntsman should begin drawing at the farthest cover down the wind, and proceed from cover to cover up the wind, till he finds; these advantages will attend it, he will draw the covers more speedily, there will be less difficulty in getting hounds away, and as the fox most likely will run the covers already drawn, there is the less probability of changing, and the covers which are up the wind, beyond where the fox is found, remain perfectly undisturbed.

Never hunt the small, until the large covers have been well ratted; for it would be bad policy to drive from the former to the latter to increase the number. If foxes are meant to be thinned and differed, hounds must throw off at the same cover, so long as a fox can be found. Hounds that come away with the first fox that breaks, do not disturb the cover, and may expect to find there again the next day; but where foxes are fierce, the same cover should never be drawn two days following.

Furze covers cannot be drawn too close, and if a fox is there found, he should never be hallowed until quite clear of them; from such places, hounds are sure to go off well with him, and it would be the height of cruelty to lead him back into the bounds mouths.

Long drags in large covers give advantage to the fox, who frequently takes the hint and lets off; this may be prevented, by throwing hounds into that part of the cover where he is most likely to kennel, the huntsman should then be careful not to take the heel of the drag. When a fox gets to far the start of hounds, that they are obliged to hunt after him with a bad feet; if foxes are in plenty, they had better be flapped, and find another; yet if this was a constant practice, it might make the hounds indifferent when upon a cold scent, and hounds should be made to believe,
HUNTING.

When hounds approach a cover intended to be drawn, and dash away towards it, whippers-in ride to flop them; they had better let them alone, it checks their drawing, and it will be soon enough to rate, when they have found and hunt improper game. Some hounds will in this dashing style break away from the huntsman, rush to the cover, and then leap and not go into it; but hounds under such good command as not to break off from the huntsman until he encourages them, will be then so confident, that they will not return to him again, but proceed to find their game with an eager determination.

While hounds are drawing, the company should place themselves so that a fox cannot go off unseen. Gentlemen should take this necessary part of fox-hunting to themselves; upon such occasions, when two gentlemen are seen together, it is a reasonable conclusion, that one of them at least knows nothing of the matter. The greater number of those who ride after hounds are no sportsmen; few gentlemen will take pains to flop a hound, although he should run riot close beside them, or will stand quiet a moment, although it is to hallow a fox, and thereby to promote the amusement they are in pursuit of.

The first day a cover is hunted, there is plenty of foxes, and blood is wanted, let them not be hauled back into the cover, which is the usual practice, but allow some of them to get off, otherwise with continual changing, and sometimes running the bed, it is probable the hounds will not kill any. Another precaution may be also necessary, that is, to flop such earths only as cannot be digged; if some foxes go to ground, and blood be wanted at last, it will then be known where to get it.

Covers near the kennel should not be drawn while foxes can be found elsewhere; it will render them certain places when hounds go out late, or may otherwise be in want of foxes; they should not be much disturbed after Christmas, foxes will then refer to, and breed in them, and they can be preserved with little trouble.

Before hounds are drafted, let the huntsman determine within himself the number it will be proper to take out, and also what young hounds he can venture in the country he is going into. Much accuracy is required in drafting hounds properly, nor can it be done with any exactness, without some method. Too many huntsmen deem it immaterial, which they take or which they leave, provided they have the number requisite. A perfect knowledge in feeding and drafting hounds, is the most essential part of fox-hunting; good hounds will need but little assistance afterwards. By feeding, is meant the bringing the hound into the field in his highest vigour, and this can be done but by a differentiation of the different constitutions of so many animals, some of which must be fed sparingly, and yet frequently, to maintain the full force of their powers. By drafting, is particularly meant the taking out an unsteady hound, nor any that are not likely to be of service to the pack. To hunt two days following with a small pack, calls forth the greatest nicety to make the most of it; some consideration is also necessary to place hounds to the greatest advantage, where foxes are either plentiful or very scarce; a huntsman should be able to marshall every hound, giving to each his proper rank; without this knowledge, he cannot make a draft as he ought. There are in most packs some hounds that aid little in killing the fox; it is the judicious drafting off such hounds, that is a certain sign of an intelligent huntsman.

When foxes are numerous, there is no occasion for an early hour, and when they are weak, by hunting late, they give better chances; when foxes are strong, the hounds ought then to have the advantage which hunting early affords them. When hounds go out late, they should immediately proceed where it is likely to find, which, for the most part, is that cover where hounds have been left in; if a fox is not soon found, a long and tiresome day is generally the consequence; when the cover is thick, particularly if it be furry, it should be drawn slowly, a fox at a late hour will keep his kennel, until hounds come close upon him.

A huntsman, although he ought to be as silent as possible when his hounds go into a cover, cannot be too noisy at their coming out of it again; and if at any time he should turn back suddenly, let him give as much notice of it as he can to his hounds, or many will be left behind, and should be turned down the wind he may see no more of them.

Gentlemen are generally in too great haste when a fox is first found, hounds are always mad enough when they find, and the enthuiafiai attending this diversion, is at this crisis particularly to be restrained; it is quite time enough for it to appear when hounds are away, and well settled to the scent. The huntsman should let off with the foremost hounds, so hounds can then dip the wind, and get on the scent after, but in pursuing hounds forward whilst the scent is good, care is to be taken that they are not hurried beyond it when it is bad; he should keep his hounds in such a condition that they will not be able to follow it as to enable him to see how far they carry the scent, without this, he can never make a cast with any certainty. It is the huntsman's business to be ready at all times to lend that assistance, which when they are first at a fault is then most critical, a fox-hound at that moment will exert himself moff, he afterwards becomes more indifferent about his game. Tho' houndsmen who do no get forward enough to take advantage of this eagerness, and direct it properly, are seldom sufficiently skilled in hunting to be of much use to hounds afterwards.

With a high scent, hounds cannot be pushed on too much; fearmen keep the forward, the hounds together, or let in the tail hounds, and enliven the sport, but in cover, should be given with the greatest caution; halloo's are of service when hounds are running up the wind, for then none but the tail hounds can hear them; when running down the wind, there should be no more halloo's than are necessary to bring the tail hounds forward, for hounds that know their business, when upon a scent, rarely want encouragement.

When hounds are at a check, every one should be silent and stand still; the huntsman had better let the hounds alone, or content himself with holding them forward, without taking them off their noses; should they continue at fault after having made their own call, (in which not a word should be said to them, and which the huntsman should always faintly encourage them to do, as they will of themselves spread more, and try better for the scent than he can make them;) it is then his business to assist them, but except in some very particular instances, such as to get beyond the scale of the flock, or where the fox has been confined by farmers' dogs; (in the former case, much time is saved in keeping hounds forward, and not suffering them to try through a flock of sheep; and in the latter it is the only chance of getting hounds to hit upon the scent, or its all serving them to hunt up to their fox afterwards;) without these reasons, or others equally urgent, hounds should never be cast so long as they are inclined to hunt. It is the judiciously preventing hounds from losing time by hunting when they might run, and the encouraging them to hunt when they cannot run, that shows a good sportsman; for though too much
Hunting.

muck help will make them flack, too little will make them tye on the fence and hunt back the neck. The huntman should observe the tail hounds, they are leath likely to over-run the fence, by them he may see how far they brought it; in molt packs there are some hounds that will saw the point of a fox, which, if attended to, may direct his view; when such hounds follow flowly and unwillingly, he may be certain the rest are running without a sent; but a huntman should by no means turn back on seeing hounds at head when first at a check, of which he has no opinion; they may be right, and he should by a short call forward be sure they are wrong, before his own suppositions of the fox being gone another way, are to be indulged.

When hounds are at fault, flaring about and trailing to their eyes and ears, a forward call is the leath likely to regain the scent; the place where they left, is the most probable spot for them to hit the scent, and hounds knowing where they left the scent will there try to recover it, of a wide call often to be made without good reason; the scent should be tried to be retrieved by crossing the line of it, and a huntman, by attending to this, will not fail to make a good call, if he observes the point of the fox. When hounds cannot hit off a fault by themselves, the first call should be speedy, then the scent is then good, and hounds not likely to go over it. Every huntman should adopt these rules; with a good scent his call should be quick, with a bad scent, slow, and when hounds are picking along a cold scent, be it not to call them at all.

When a fox is killed, hounds should eat him ravenously: he should be flung across the branch of a tree, and the hounds suffered to bay him for some minutes before he is thrown amongst them, it will shew hounds the meaning of taily bo, and learn them to fly like lighting to it; it will also make the hounds more eager, will let them all in, they will recover their wind, and eat him more readily.

When a fox is suspected to be gone to ground, the huntman should try all round, and be perfectly satisfied that the fox is not forward, before he tries the earth, as a fox will frequently run over an earth, and sometimes go into, and not lay in it. When a fox goes to ground, after a long chase, and hounds want blood, it is best to kill him on the earth, the holes should be all stopped whilst digging, left he should bolt; when this happens, it caust no small confusion, the hounds are disordered and asleep is different places, the horses often at a distance, and many a box by taking this advantage of the moment has saved his life.

With respect to the digging of foxes which hounds run to ground, if the hole be straight and earth flight, follow it, and in following the hole, by keeping below its level, it cannot be lost; but in a strong earth, the belt way is to let the terrier fix the fox in an angle of it, and a pit be then sunk as near to him as can be, a terrier should always be kept at the fox, who otherwise may move, and in hound-ground dig himself further in; in digging keep plenty of room, and take care to throw the earth where it may not have to be moved again.

The time for leaving off hunting, as much depends upon the quantity of foxes as on the country hunted; no good country should be hunted after February, nor should there, where hounds regularly hunt in the feaon, be any hunting at all after March. Spring hunting is fed deftruction to foxes, and ought not to be attempted but in countries never visited by hounds in the hunting season, or where the foxes are wished to be destroyed by wholesale; in one week, hounds by killing a brace or two of hich foxes, either in cub, or that have full littered, murder as many as would shew diversion for a whole feaon.

Notwithstanding the common law allows of the hunting of foxes and badgers (being beasts of prey) in another man's ground, because their defection is a public benefit, and by the old law the parifh officers are to give a certain sum by the head for both male and female, to promote it; yet the digging and breaking the ground to unearth them, is held to be unlawful, and in the case of Gedge v. Minne, it was determined, that the defendant could not justify digging for a badger; the breaking ground to flap an earth is also illegal, and the owner of the ground may maintain an action of trespass; it was also decided in the aforementioned case, that if a persun goes into the ground of another, to beat or draw for a fox or a badger in order to hunt it, this action for trespass lies. Daniel's Rural Sports, p. 84-133.

Hunting, Hare. A hare the first year is called a little; the second year, a hare; the third, a great hare. See Hare.

Each part and member of the hare is formed for celerity. The head is round and short, of a convenient length; the ears long and lofty, to hear the enemy at a distance, and focus itself in time; the lips continually move, sleeping and waking; and the eye is too big and round for the lid to cover it, even when asleep; so that the creature sleeps as it were on the watch. Straight forward there is a deficiency in the hare's sight, so that when closely pursued she will run against objects in her way. The break is capacious, and fitted to take more breath than that of any other beast. They feed abroad, to conical their forms; and never drink, but content themselves with the dew. The hare's ears led the way in her chase; for with one of them (it has been said) the hearkeneth to the cry of the dogs, the other being stretched forth like a tail to promote her course.

Others, however, have asserted that this notion is ridiculous. Whenever the hare pricks her ears on end, or draws one apart from, or more forward than the other, it is to listen more distinctly on that side the forward ear inclines; had Nature designed any sagular aid to her foot from twitching forth the ears, the would have supplied her with two pairs, one to lie flat upon the shoulders for looking, whilst the other, and never would the hare have had more occasion for both, than when feverly coursed, at which time, the ears she has may be observed to lie close to the neck; and although she is compelled, when thus premed, to try every shift to escape, this quality of failing by the ears is never seen; both ears are very briskly applied to catch the smallest sound of the greyhound behind, by which she accordingly retards or increases her celerity.

The hares of the mountains often exercize themselves in valleys and plains, and through practice grow acquainted with the nearest way to their forms; those which frequent bushes and brakes are not able to endure labour; nor are very swift, being tender footed, and growing fat through ditionance of exercise.

When the hare has left the dogs far behind, she goes to some hill or rising ground, where, rearing on her hinder legs, she observes at what distance her pursuers are.

The trail, i.e. the path which the hare takes in going to her feast is long, says Xenophon, in his Observations upon Hare-hunting, in proportion to the length of the night. In the winter, he says, there is no scent early in the morning, when either a hoar or a hard frost occurs. The trail is also spoilt by much dew, and by showers after a long drought.

The scent is naturally stronger in wood-hares than field-hares; but in all hares it is strongest when they feed on green corn. The scent of young hares is said to be stronger than that of those full-grown, the weakness of their limbs suffering the whole body to touch the ground. In winter mornings,
the scent does not lie till the frost be a little thawed; and it may be added, that a hare always leaves more scent when she goes to relief, than when she goes to form.

Her footsteps are more seen in winter than summer; because, as the nights are longer, they travel farther. Their prints are very uncertain at the full moon, at which time they leap and play together. The young, it is to be observed, tread heavier than the old, because their limbs are weaker. A buck, or male hare, is known by his beating the hard highways, feeding farther out in the plains, and making his doublings of a greater compass than the female, who keeps close by some covert side; turning, winding, and crossing in the bushes, like a coney, and rarely running out an end; whereas the buck, having once made a turn or two about his form, runs straight forward for four or five miles, or more, without once turning his head. Add, that the buck is known, at his rising out of form, by his hinder parts, which are more white, and his shoulder, which is redder than the does. His head is also shorter, and his ears more grey.

The hare regulates its conduct according to the weather. In a moil day he holds the highways more than at any other time, because the scent is then moit apt to lie; and if she come at the side of any young grove or spring, the for-bears to enter, but fquats down in the side, till the hounds have over-shot her; upon which she returns the same way she came, without turning into any covert, for fear of the wet and dew hanging on the boughs.

Regard is also to be had to the place where the hare fits, and upon what wind; for if her form be either upon the north or south wind, she will not willingly run into the wind, but aside, or down the wind; on the contrary, if the form on the side of the water, it is a sign she is well and meatfed, and in the course will make all her doubling and croffing about brook-fides and near plashes; for her scent, under this condition, being very strong, she needs a place that will take but little. Sometimes, when hunted down, she will flart a fresh hare, and squat in the same form; at other times, she will creep under the door of a sheep-cote, and hide among the sheep, or run amon a flock of sheep, and will not, without the utmost difficulty, be taken from among them. Add, that some will take the ground like a coney; this is called going to vault.

Some hares will go up one side of the hedge, and come down the other; and it is said that a hare, being forely hunted, has got upon a quickset hedge, and ran a good way on the top of it, and then leaped off upon the ground; and that it is no unusual thing for them to take themselves to furze-bushes, and leap from one to another, whereby the hounds are frequently in default. These accounts, however, are difregarded by some as fabulous.

A hare, it is said, does not live above seven years at moft, especially the buck; and if he and the doe keep one quarter, they will not suffer any strange hare to flart by them; whereas the proverb, "The more you hunt, the more hares you shall have;" since, having killed one hare, another comes and poiffles his form.

In entering a young kennel of hounds, regard must be had to the nature of the country and of the quarry; for, according to the place wherein they are entered, and the game first given them, will they afterwards prove. Thus, if they be entered in a champaine country, they will ever after more delight to hunt there on any other ground. The best time, it is said, for the entering of hounds is in the heat of the day; and about October or November, the weather being then temperate, and young hares that have not been hunted, are more easily taken for their encouragement. Hounds, after the age of two years, should be hunted three times a week, if they feed well, and may be kept out the greatest part of the day, to try their strength. See Entrance and Hounds.

Having found where a hare hath relieved in some paturage, or corn-field; to find her form, the season of the year, and the state of the weather are to be considered. In the spring or summer, a hare will not flit in the bushes, but frequently offends with pipisires, snakes, and adders; but will sit in corn-fields, and open places. In winter they choose to sit near towns and villages, in tufts of thorns and brambles, especially when the wind is northerly or southerly. According to the season, and nature of the place where the hare is accustomed to sit, there must be your hounds, and flart her; which is better sport than trailing of her from her relief to her form. Having flarted her, she leaps in, and halloo in the hounds till they have undertaken it: crying, that, that, or there, and go on with full cry; then re-cheat them, and follow at a distance, taking care not to forward them too much at first, as being apt, if the first heat, to overthrow the game. Some of the early sportsmen never permitted the hare to be hallooed, or the hounds to be affiled when they were at fault, but suffered them to work it out by themselves, which, though tedious, was considered as a sure way to ascertain the goodnes of the hounds. Above all things, mind the first doubling the hare makes, which is to be a key or direction for the whole day; all the other doublings she afterwards makes being like the first. According to the policies you see her use, and the place where you hunt, make your compass, to help the defults, great or little, long or short; always seeking the moistest and most commodious place for the hounds to scent in.

A young huntman, says an ingenious sportsman, should take care, when the scent lies well, always to keep himself far behind. At such a time, especially if it be against the wind, it is impossible for the hare to hold forward, nor has any mode of escaping, but to flit short, and when all are pait, to deal immediately back. This is often the occasion of an irrecoverable fault in the midst of the warmest sport, and is the beat trick the hare has for her life in deceiving weather.

If the huntman, therefore, is not too forward, he will have the advantage of fixing her manoeuvre, and of affiling his hounds at this critical moment.

Upon sight of the hare, avoid, above all things, the vile practice of hallooing hounds off a fecst, to lay them on after a sawce, it not only spoils the dogs, by accruflming them at every fault to hiten for, and expect the hallow, but it is foul sporting; equally unfair and to be condemned is, the suffering the pricks of the hare's footing to be smoothed when she runs the foal; for although it is admitted that by such prickings and discovering her fleps, no hare can escape, yet it is an unmanly mode of affiling hounds, which no huntman, who is a sportsman, will ever be guilty of himself, or condeem to make use of when done by others.

The huntman should never be noisy when a hare is first flarted; let him not only check his own forwards, but that likewise of the inexperienced sportsman. Hounds are apt enough in the first heat of their mettle to overthrow their game, and hours of fair sport have happened from driving them too fast. Too many people think a chief part of hunting consists in halloowing loud and riding hard, but they are mistaken, and must not be offended should the huntman swear at their performances. No tongue can be allowed but his, nor, at this peculiar time, ought any one to be more forward.

The chief considerations for the huntman, when the hounds

...
Hunting.

Hounds are at default, are, how long the hare has been on foot, and how far the hounds make it good; if the hare has not been long and hard pressed, he must expeditiously try a wide circle, and so perfest in contracting his circles, until he returns to the place where the dogs threw up. Should the hare have been drove hard, or be nearly dead run, the huntsman need only try a small compass, and that slowly and cautiously, for the will only lap off a few rods and quail, until one or other of the dogs jumps upon her.

A huntsman should be careful of talking too loud to hounds, and in a key which instead of cheering confounds them. Give me, says this author, a fellow of everlasting patience and good temper, who does not consider hunting merely as his lyfes, but who naturally loves it; one with a clear, moderate voice, that speaks to an old hound when at fault frequently and with quick-eyes, and cherishes him in a tone that enforces courage, and induces him to floup perpetually to recover the scent. It is by no means the huntsman's business to endeavour by pricking the hare to hit her off; in the first place it is unfair, and, secondly, whilst he is poring with his eyes upon the ground, not one in twenty of the hounds will have his nose to it. If there is a long default, the huntsman should attend to the tender-nosed dog, which perhaps he disfregared in the morning as a loller, and whom he pronounced worthy of a halter for opening at nothing; his superior excellence of scenting may now shew itself to have merited a different judgment, and may encourage some flourish hound to hoop, which he would not otherwise do.

A huntsman is never to give up a default whilst day-light and weather permit; if the hare is not killed and taken up, there is no good reason why it is not to be recovered, and it should be a leading maxim, that it is always as easy to recover a left hare as to start a fresh one.

In the opinion of Mr. Beckford, the number of hounds should not exceed twenty couple in the field, from the difficulty of getting a greater number to run well together, and a pack of harriers (as well as fox-hounds), are incomplete if they do not. A hound that runs too fast for the real ought not to be kept. Some huntsmen load them with heavy collars, or tie a long flap round their necks; a better way would be to part with them. Whether they go too slow or too fast, they shouild be drafted. The hounds most likely to show sport are between the large, slow hunting harrier, and the little fox beagle; the former are dull, heavy, and too slow; the latter are lively, light, and too fleet. The first fort have most excellent noses, and will kill their game at last, if the day be long enough. The other, on the contrary, daft and are all alive, but every cold blast affects them, and in a deep and wet country it is not impossible but that some of them may be drowned. His opinion respecting the huntsman is, that he should not be young, and for patience he should be a very Grizzle; the quieter he is the better, and he should have perseverance and never give up a hare when it is possible to hunt her, as she is faire to floup, and therefore may always be recovered; he judiciously remarks, that were it cullomy to attend to the breed of huntsmen as well as to that of hounds, the family of the scented gentlemen, mentioned by the Spectator, would furnish an excellent corps, and that a female of his lineage, married to a knowing huntsman, would probably produce a perfect hare-hunter. The whisper-in to a pack of harriers should not be allowed to floup a hound or smack his whip, without the huntsman's order. Noise and gattle are directly adverse to the first principle of hare-hunting, which is to be quiet and leave the hounds to themselves. If a long fault makes the huntsman's affability necessary, and the hare should have headed back, he will observe whether she has turned of her own accord, or has met any thing in her course to turn her. When he calls his hounds, let him begin with a small circle, if that is unsuccessful, try a larger, and as a hare generally revisits her old haunts, and returns to the place where she was first found, if the scent be quite gone, and the hounds can no longer hunt, that is as likely a call as any to recover her. Let him remember in all his calls, that the hounds are not to follow his horse's heels, nor are they to carry their noses in the air. At these times they must try for the scent, or they will never find it; and he is to make his call either quick or slow, as he perceives his hounds try, and according to the goodnens or badnens of the scent.

When hounds are at a check, the huntsman should not move his horse one way or the other. Hounds lean naturally towards the scent, and if nothing be said, will soon recover it: if a hound is spoken to at such a time, calling him by his name, (which is too much practised,) he feldon falls, says Mr. Beckford, to look up, as much as to say, What the Fucc do you want? Had he the faculty of speech, he would add, before he flopped to the scent again, Too fool, let me alone. When hounds are at fault, no word should be said; no other tongue should be heard but that of a hound; and so inflexible was a friend of Mr. Beckford who kept harkers, in this particular, that a gentleman accidentally coughing whilst his hounds were at fault, he rode up to him immediately, and said "I wish, sir, with all my heart, that your cough was better."

When the hare is first started, says Mr. Beckford, sportmen cannot be too quiet. Hounds through the whole chase should be left almost entirely to themselves, and never be much hallooned; when the hare doubles, they should hunt through these doubles; nor is a hare hunted fairly if hunted otherwise; they should follow every step she takes, as well over greatly falls, as through flocks of sheep, nor should they be ever cast, if able to do any thing without it. On high roads and dry paths, the huntsman should always be doubtful of the scent, nor give them much encouragement; but when a hit is made on either side, it is then right to cheer them as much as you please. A hare generally describes a circle in her flight, larger or smaller, according to her strength and the openness of the country. In exclusoeres and where there is much cover, the circle is so small that it is a conftant puzzle to the hounds. Besides running the field, they frequently make doubles, which is going forward, to tread the fame steps, back again, on purpoze to confude the hare; and the same manner, in which the first double is made, they stillly continue, whether long or short. This information, says Mr. Beckford, if properly marked by the huntsman, may be of service in his calls. When hares make their doubles on a high-road, or dry path, and then leave it with a spring, it is often the occasion of a long fault: the spring which a hare takes on these occasions, is hardly to be credited, any more than her ingenuity in thus trying to escape. Often, after running a path a considerable distance, he will make a double, and floup until the hounds are past her; she will then fllop away, and return the same way she came; this is the greatest of all trials for hounds. It is ho but a foil', that in the belt packs there are not many hounds that can hunt it; tho' hounds must be followed that can, and the foil when he breaks it, (which in all probability the will soon do, as the know thinks herself secure,) be tried to be hit off. When the scent lies bad in cover, he will sometimes seem to hunt the hounds. Particular directions, says Mr. Beckford, should be given to the huntsman, to prevent the hounds in his
his power, from shaving harrets. In furze they lie very cloe, hedges are also dangerous: the belt way is to have the hedge well beaten some distance before the hounds, for if the huntman beats the hedge himself, as is the general practice, the hounds are always upon the watch, and a hare must have great luck to escape them all. Hares feldom run so gallantly as when they do not know where they are; in a fog they run well, if they set off down the wind, they rarely return, and hounds cannot then be pushed on too much; when the hare is finking, the old hounds will get forward, they, then, will run at head.

Keep no balhers or hounds that run false; the los of one hare is more than such dogs are worth.

Hunting. Hart or Stag. (See Cervus Elaphus.) This animal the first year is called a calf, or bind-calf; the second year, a knubber; the third, a brock; the fourth a stagward; the fifth a stag; the sixth a hart.

The female is called a kind. The first year she is a calf; the second a heare, and sometimes a brocket's fitter; the third a bind.

Terms occurring more especially in hunting the hart, and not yet explained, are as follow. The print or impression, where a deer has lain, is called a layer; if it be in covert, or a thicket, it is called his harbour; where a deer has passed into a thicket, leaving marks whereby his bulk may be guessed at, it is called an entry; when they call their heads they are said to meet; when they rub their heads against trees, to bring off the peels of their horns, they are said to frey; when a deer, hard hunted, takes to swimming in the water, he is said to go to fall; when they turn head against the hounds, they are said to bay; when the hounds touch the fent, and draw on till they put up the hart, they are said to draw on the floth.

As to the nature and qualities of the hart, it is to be observed that he is an excellent swimmer; there being infliances, when fore hunted, of his plunging in the sea, and being killed by fishermen twelve miles from land. When, in going to rut, they have occasion to cross a great river, or arm of the sea, it is said they assemble in great herds; the strongest goes in first, and the next of strength follows; and so one after the other, relieving themselves by staying their heads on the buttocks of each other.

The hind commonly carries her calf eight or nine months, which usually falls in May; some have two at once; and they always eat up the skin wherein the calf lay. As the young grow up, the old one teacheth it to run and leap, and how to defend itself from the hounds.

The hart is amazed at hearing any one call, or whistle, in his lat; if you cry ears, ears, or take head, you will see him instantly turn back, and make some little stand. His sense of hearing is very perfect when his head and ears are erected; but very imperfect when he holds them down; whenever he pricks up his ears, he is known to be apprehensive of danger. When he is on foot, and not afraid, he wonders, and takes a pleasure to gaze at every thing he sees.

The hart is long lived, but lefs so than some persons have conceived. (See Cervus Elaphus.) The principal marks of his age are taken from his head, yet this is somewhat precarious; some having more croches thereon at the same age than others.

The capture of this beast requires great art and attention. When the hunter goes for sport, he is first to encompass the beast en fon gilet, in her own layer, and thus unhursh he in the view of the dogs, so that they may never lose her lat or footing. But note, a considerable degree of choice and discretion is here required; for he may not fet off upon every one, either of the herd, or those which wander solitarily: the young, the small, &c. are to be passed over; and partly by flight, and partly by the fouling, fewmets, the largenes of the layer, &c. he must mark; judgment of the game, singling out for that purpose the largest head in the whole herd.

There are divers means for knowing an old hart; viz. by the flot, the entries, the abaturs, and the flatus, gait, and sounds, fraying-flocks, and the head and branches. 1. As to the flot. The treadings of the hart's foot are to be carefully noted: if you find the treadings of two, the one long, and the other round, yet equally big, the longest flot declares the largest hart; add, that the old hart's hind foot never over-reaches the fore-foot, as that of the young one does. 2. The frowning is chiefly to be judged of in April or May; if it be large and thick, it signifies the hart to be old. 3. To know the height and thickens of the hart, observe his entries and galleries into the thicket, and what boughs he hath over-ridden, and mark from hence the height of his belly from the ground; for a young deer usually creeps low, as he passes to his harbours, and goes through places which the old one, being lofty and lately, will not flop to. 4. By his gait it may be known whether the hart be large, and whether he will stand long before the hounds; if he have a long step, he will stand long, being swift, light, and well breathed; if he have a great flot, which is the sign of an old deer, he will be a latter. As to his fraying-poll, note, that the older the hart is, the sooner he goeth to trust, and the greater is the tree he chooseth to fray upon; it being necessary it be such as may not bend. Now, to seek or find out a hart in his haunt, or feeding-place, it is to be observed, that he changes his manner of feeding every month. From the conclusion of the rutting time, which is in November, they feed in heaths and broomy places. In December they herd together, and withdraw into the strength of the forests, to shelter themselves from the severe weather, feeding on holm-trees, elder-trees, brambles, &c. The three following months they leave the herding, but keep four or five in a company, and in the corners of the forest they will feed on the winter pastures, sometimes making their excursions into the adjoining corn-fields, if they can perceive the blades of wheat, rye, &c. appear above ground. In April and May they rest in thickets and shady places, flitting very little till rutting time, unless disturbed. The three succeeding months they are in their pride of grace, and resort to springs, copses, and corn-fields. In September and October they leave the thicket, and go to rut; during which season, they have no certain place either for food or harbour.

Having found out the game, the hunters dissemble and call off the dogs; and some on horseback, others on foot, follow the cry with the utmost art, observation, and speed, remembering and preventing the fable turning and headning of the hart; flitting with dexterity and intrepidity to leap hedge, pales, ditch, &c.

The utmost address and circumspection are to be used to keep to the beast first attempted, and to prevent the dogs from pursuing any other; this, in effect, makes one of the principal difficulties and gories of the chase; the beast having a hundred devices to put off some other head for his own: sometimes he will fend forth some other little deer in his head into the dogs' way, laying close at this time himself; on which occasion the huntman is to send a retreat, and break off the dogs, and take them in lean, till the game be recovered.

Sometimes he will purposely seek out other deer at layer, and route them to make the hounds hunt change, himself lying down...
HUNTING.

When which you endeavour this will be the concert of mountains. He will break into one thicket after another, to find deer, roe-deer, gathering them together, and herding with them, and even beating some of them into his tent, that he may the more easily escape. Finding himself spent, he will break hard, and fall to doubling and crowding in force hard beaten highway, always running against the wind, not only to cool himself, but the better to hear the voice of his pursuers.

The last refuge of a hart foressey hunted, is the foil; keeping the middle for fear,leaf by touching a bough, or the like, he may give scent to the hounds. He always sways against the strake; whence the old rule, "He that will his chase find, let him try up the river, and down the wind." In taking foil, he will sometimes cover himself under water, so as to shew nothing but his nose.

Where opportunity of water fails, he will fly into herds of cattle, as cows, sheep, &c. and will sometimes leap on an ox, cow, or the like, laying the fore part of his body thereon, that so touching the earth with his hinder legs, he may leave a small or no scent behind. What is further still, the chief huntman of Lewis XI. relates, that a hart which was in hard chase of, leaped into a great tall white thorn, which grew in a shadowy place, and there blood aloft till he was run through by a hound, rather than he would stir.

The hart being killed, the huntman with his horn windeth the fall of the bell; upon which every one approaches: the skillesleft opens the breach, rewarding the hounds with what properly belongs to them; the houndsman, at the same time, dipping bread in the skin and blood of the bell to give the hounds their full satisfaction.

The hart is known to be spent by his running stiff, high, and lampering, by his mouth being black and dry, and without foam on it, and his tongue hanging out; though he will sometimes close his mouth to deceive the spencers; and by his flot, for he will sometimes close his claws together, as if he went at leisure, and immediately again open them wide, making great glidings, and hitting his dewlaps upon the ground, &c. When quite spent, and close both, or intercepted on all sides, the hart usually takes to bay, and moves force with his head against the first man or dog thatches is upon him, unless prevented with a spear, sword, or the like. Hence it is very dangerous going in to a hart at bay, either on land or in the water, especially at rutting time, for then they are more than ordinarily fierce.

The hart being killed, his death is solemnized with great ceremony. The first thing, when the huntmen come in, is, to cry, "Wear banche," that the hounds may not break into the deer: having secured this, they cut his throat, and blood the younger hounds, to make them love deer; and learn to cap at his throat; then having blown the mort, and all the company being come in, the most distinguished person, who has not taken aay before, takes up the knife, and lays it across the belly of the deer, (some of the affillants holding by the fore-legs, and at the base the huntman drawing down the pizzle,) and thus he draws the knife along the middle of the belly, beginning near the brisket, cutting deep enough to discover how fat he is. Then the most skillful person breaks up the deer, by first flushing the skin from the cutting of the throat downwards, making the other, that the ordure may not break forth, and then paunching him, and rewarding the hounds with it.

Lately, the person that took the say, being presented with a drawn hanger, he is to cut off the head; which done, and the hounds rewarded with it, the concluding ceremony, if a buck, is a double; if a fallow, a treble mort, blown by one, and a recast in concert by all that have horns: the whole is then concluded with a general whoop, whoop.

Hunting, Otter. See Otter. The otter is to be hunted by particular dogs, called otter bounds, and also with special instruments, called otter spears. To find him out, some are to go on one side of the river, and some on the other, beating all the way on the banks, with the dogs following. Thus it is soon found if there be an otter in that quarter; for the otter cannot endure long in the water, but must come forth to make his spraints (excrements), and in the night sometimes to feed on grafts and other herbs. If the hounds find an otter, look in the soft and moist places, to learn by the prints which way he went his head; if these make no discovery, it may be partly perceived by the spraints. This done, follow the hounds, and lodge him as a hart or deer.

The otter always endeavours to keep to the water, where he is master. In hunting him, therefore, you are to be ready with your spears, to watch its vents; for that is the chief advantage: if you perceive where the otter swims under water, drive to the bank before him, where you expect him; and then endeavour to strike him with the spear, if you miss, pursue him with the hounds; which, if they be good, and well entered, will come chanting and trailing along the river-side, and beat every tree, root, every oyster-bed, and tuft of bulrushes; nay, sometimes they will swim in the water, and beat it like a spaniel; by which means the otter can hardly escape.

If the beast find himself wounded with a spear, he usually makes to land, where he will maintain a furious battle with the dogs.

Hunting, Roe-buck. See Roe-Buck, Roe Deer, and Cervus Capreolus.

We have no roe-deer in England; but they abound in the Highlands of Scotland, Germany, Africa, &c. And it should seem that they have been more common among us, our huntmen still retaining the proper terms for the chase.

They make good sport, large and long, and fly end-way. When a roe croles as doubles, it is called troopying. Their swinehappens not only on the earth, but in waters, through which they cut their way as with oars; whence they love lakes and streams; breaking the floods to come at fres pature, feeding on rushes, &c.

Horns grow only on the male: being fet with fix or seven branches not palmed, but branch, yet shorter than fallow-deer. After rutting he calls himself.

They are said never to wink, not even when asleep; for which conceit their blood is by some fanciful people preferred to persons dim-fighted or purblind. The tail of this beast is less and shorter than that of a fallow-deer, insomuch that it is questioned whether it ought to have that denomination.

They keep mostly in mountains among the rocks; and when hunted, Mertid tells us, will hang on them with their horns, to delude the dogs. They are often taken by contrary, their voice, which the huntman does by the affin-
By one who designs to match his horse for his own advantage, and his horse's credit, it is not to flatter himself with the opinion of his horse, by fancying that he is a twiff, when he is but a slow galopper; and that he is a whole running horse (that is, that he will run four miles without a bar at the height of his speed) when he is not able to run two or three.

Very probably some gentlemen are led into this error, by their being mistaken in the speed of their hounds, who, for want of trying them against other dogs that have been really fleet, have supposed their own to be so. When, in reality, they are but of a middle speed; and because their horse, when trained, was able to follow them all day, and upon any hour, to command them upon deep as well as light earths, have therefore made a false conclusion, that their horse is as swift as the beetle; but upon trial against a horse that has been rightly trained after hounds that were truly fleet, have bought their experience perhaps full dear; therefore it is advisable for all lovers of hunting to procure two or three couple of tried hounds, and once or twice a week to follow after them a train-scene, and when he is able to top them all on forts of earth, and to endure heats and colds stoutly, then he may better rely on his speed and toughness.

That horse which is able to perform a hare-cape of five or six miles briskly and courageously, till his body be as it were bathed in sweat; and then after the hare has been killed, in a nipping frosty morning, can endure to stand till the sweat be frozen on his back, so that he can bear being pierced with the cold as well as the heat, and then in that extremity of cold to ride another cape as briskly and with as much courage as he did the former, that horse which can thus endure heats and colds is most valued by sportsmen. Therefore, in order to make a judgment of the goodness of a horse, observe him after the death of the first hare, if the chase has been in any degree brisk; if when he is cold he shrinks up his body, and draws his legs up together, it is an infallible sign of want of vigour and courage; the like may be done by the slackening of his girths after the first chase, and from the dulness of his teeth, and the dulness of his countenance, all which are true tokens of faintness, and being tired; and such a horse is not to be relied on, in case of a wager.

Here it will not be improper to take notice of the way of making matches in former times, and the modern way of deciding wagers. The old way of trial was, by running so many train-scents after hounds, as were agreed upon between the parties concerned, and a bell-course, this being found not so uncertain, but more durable than hare hunting; and the advantage confined in having the trains laid on earth most suitable to the qualifications of the horses. But now others choose to hunt the hare till such an hour, and then to run this wild-goose chase (which see), a method of racing that takes its name from the manner of the flight of wild-goose which is generally one after another; so the two hares, after running of twelve-score yards, had liberty, which horse foreever could get the leading, to ride what ground he pleased, but the hindmost horse being bound to follow him, within a certain distance agreed on by articles, or else to be whipped up by the riders or judges which rode by; and whichever horse could distance the other, won the match.

But this chase was found by experience so inhuman, and so destructive to good horses, especially when two good horses were matched; for neither being able to distance the other, till both were ready to sink under their riders through weakness, that oftentimes the match was fair to be drawn and left undecided, though both the horses were quite spoilt.

This brought up the custom of train-scents, which afterwards was changed to three heats, and a straight course; and that the lovers of horses might be encouraged to keep good ones, plates have been erected in many places of England. The fewer of these before you come to the course, if your horse be fiery and mettled, the better, and the shorter the distance the better. Also, above all things, be sure to make your bargain to have the leading of the first train, and then make choice of such grounds where your horse may best show his speed, and the fleetest dogs you can procure: give your hounds, as much law before you as your tried will allow, and then, making a hols, try to win the match with a wind; but if you fail in this attempt, then bear your horse, and give him for the course, but if your horse be flow, but well warmed, and a true spurred one, then the more frequent you run before you come to the straight course, the better. But here you ought to observe to gain the leading of the first train; which in this case you must lead upon such deep earths, that it may not end near any light ground; for this is the rule received among horsemens, that the next train is to begin where the last ends, and the left train is to be ended at the starting place of the course; moreover remember to end your left on deep earths, as well as the right.

Hunting Cape, in the language of the sportsmen, is a cap made of leather, and covered with black velvet, fitting close to the head behind, and having a semi-circular peak before, for the protection of the face in case of falls, as well as in passing through strong current during the chase. In the sporting world it is termed a "shiver."

Hunting Whip, is of different lengths in the handle or stock, and has at one end a long thing and lash, to affit occasionally in managing the hounds, and at the other a hook, hammer, or claw, for the purpose of holding or opening gates.

Hunting Saddle. See Saddle.

Hunting Cross, in Geography, a river of America, in Virginia, which runs E. and Potomac river, at the S. corner of the territory of Columbia.

Hunting Islands, a cluster of small islands in the Atlantic ocean, near Port Royal, in the state of South Carolina. N. lat. 32° 24′. W. long. 30° 57′.

Hunting Sound, a narrow channel on the coast of North Carolina, between Core bank and the continent.

Huntingdon, the principal town in Huntingdonshire, England, is situated on the northern side of the river Ouse, and is nearly connected by three bridges and a causeway, with the village of Godmanchester, whence, according to Camden, it sprang. This place is called Huntingdene in the Saxon chronicles, and Huntingtun in some ancient writings. Henry of Huntingdon, the archdeacon and historian, describes it as "surpassing all the neighbouring towns in pleasantness of situation, beauty of buildings, nearness to the towns, and plenty of game and fish." Most writers agree with Camden respecting the origin of this town; and like him, have placed the Dunlopontium of Antoninus at Godmanchester; yet the nature of the ground affords almost decisive evidence that the Roman station could not have been at that village, but was rather at Huntingdene, where the earthenworks, yet remaining, show the works to have been very strong and extensive; and even Camden's own testimony may be urged in support of the opinion, that these fortifications had a far more remote origin than is commonly allowed. "On the river near the bridge," he observes, "there is a fair built of stone, are to be seen the mound and cist of a castle, which, in the year 1017, King Edward the Elder built anew; and David the Scot, (to whom, according to an ancient historian, King Stephen gave the borough of Huntingdene, for an augmentation of his estate.)"
HUNTINGDON.

Enlarged with many works.* Now, the re-building of the castle by Edward c invices, in a great measure, its previous antiquity; and its site, as in Camden's time, still remains to prove, that no spot of ground in this neighbourhood could be better adapted for a citadel or fortress. On the north it is bounded by the river, from which it rises very abruptly to a considerable height; the outer ramparts include an area of several acres, of a square form, with the angles rounded off, and the whole was environed by a deep ditch; the banks on the south, and south east, are still very bold. Not any vestiges of buildings now remain, but the foundations may, in various places, be traced from the unevenness of the surface; the artificial mount, on which most probably stood the keep of the castle, was also surrounded by a ditch. Below the high ground, to the south-westward of the entrenchments, is an extensive and fertile meadow, called Portholom, which Camden describes as "the most fresh and beautiful that the sun ever shone upon." This meadow is partly surrounded by the Ouse river; and here the Huntingdon races are held; a small part of it, which belonged to the protector Cromwell, and is now the property of the end of Sandwich, still bears the appellation of Cromwell's Acre.

Huntingdon is a borough by prescription, and the only one in the whole county. In the time of Edward the Confessor, as appears from the Domesday book, there were in this burgh, four feodaries, in two of which were 116 burgesses, paying custom and geld, and under them 100 bordari, who helped to pay the geld; in the other two feelings were 140 burgesses, subject to all customs, and the king's geld.

Scarce any historical events are recorded as happening in this town. During the civil war, in the time of Charles I., it was pillaged by the king's troops, who were commanded by the king in person.

The religious houses, of which there were formerly four of different descriptions, are almost as entirely obliterated as the buildings of the castle. The most ancient was a priory of Austin canons founded on the spot where St. Mary's church now stands, before the year 573, as appears from a charter of that date, granted by King Edgar to Thorney abbey. The buildings have long been demolished; but the lanes which separated the cloPsi still retain their ancient appellation. The next foundation in order of time, was an hospital for a master and brethren, and several lepers and infirm people, to which Malcolm IV. king of Scotland, and earl of Huntingdon, was a great benefactor. Another hospital, for lepers and poor people, was founded by David, earl of Huntingdon, in the time of Henry II. A house of Augustinian friars was also established at the north end of the town, previous to the thirteenth year of Edward I. Huntingdon is generally rated to have been once much larger than at present; and for Robert Cotton, as quoted by Speed, ascribes its decay to some alterations made in the river by one Grey, a minister of the time, by which its navigation was impeded. Leland says, that some ages before it had fifteen churches, though, in his time, reduced to four; the rest fallen through time and neglect, but traces of their walls and yards remaining. There are now only two churches, those of St. Mary and All Saints; but the town still consists of four parishes; that of St. John being connected with A l Saints, and that of St. Benet with St. Mary's. The church of St. Mary, which is the corporation church, was rebuilt in the reign of James I., between the years 1638 and 1639, as appears from those dates over the north door-way: on the tower is the date 1633. It consists of a nave, chancel, and aisles, with a handsome embattled tower at the west end, having strong buttresses with ornamental niches at the angles. The chancel contains several monuments to the Sayer family, one of whom, George Sayer, gent. contributed largely towards the internal repairs of this edifice, and besides several other donations, gave 500l. to purchase lands, the rents to be appropriated to the ministers of the two churches. Nearly opposite to St. Mary's church is a respectable manse, now the property and seat of Sir John Arundel, bart. All Saints church, which stands on the north side of the market place, appears, from the character of its architecture and ornaments, to have been built in the time of Henry VII. It is an embattled edifice with a small tower at the north-west angle; below the battlements is a bold cornice, charged with a multiplicity of sculptures, representing human and animal heads, flowers, &c., and among them the Tudor rose and the корецки.

The principal charitable establishments in this town are, a free grammar school, well endowed; and a green cost school, wherein twenty four boys are clothed and educated. This is called Walden's charity, from Lyndel Walden, esq., who, by will dated July 1719, left a sufficient endowment for the purpose of supporting it. Among various other donations for charitable uses in Huntingdon, was the sum of 2000l. bequeathed by Richard Fihbourn, a citizen of London, who died in 1625; this money was to purchase lands, the rents of which were to be appropriated to the use of the poor; he made similar bequests to other places, the amount of the whole being 11,000l. The market place is a spacious area, on the south side of which stands the town-hall, a modern brick building, flanked, with a port of piazza in front and at the sides for the market people; and behind it the butchers' shambles. The alleys for the town and county are held here twice a-year; the lower part of the building being divided for the purpose into two courts; one for criminal, and one for civil causes. Above is a spacious assembly room, ornamented with full length portraits of their majesties, George II. and III. with their respective queens; and also a well painted picture of John, earl of Sandwich, who died in 1702. The market, which is held on Saturdays, is well supplied with provisions in general; and great quantities of corn are sold. Huntingdon had its first charter about the year 1206; king John granted it a peculiar coroner, a recorder, town-clerk, and two bailiffs, with the receipt of tolls and custom. Charles II., by a new charter,velled the government in a mayor, twelve aldermen, and an indefinite number of burgesses or common council, chosen from the principal inhabitants. This borough sent members to parliament ab origine, from the twenty-third of Edward I.; the right of returning the two members is generally understood to be possessed by the freemen and inhabitant householders, paying scot and lot; the number of voters is about 200; both the representatives are however nominated by the earl of Sandwich. The town principally consists of one street, extending, in a north-westly direction, from the banks of the Ouse, to nearly the distance of a mile, and having several lanes branching off at right angles. The streets are paved, and lighted in the winter by a small allotment levied on the householders. The ancient town appears to have spread further easterly; yet whatever might formerly have been the extent of Huntingdon, the population seems to be nearly the same as it was a century past; as bishop Gibson states the number of families it contained in 1717 to be 229, whilst the return made to parliament in 1861, records their amount to be 350, confident of 2035 persons, inhabiting 386 houses.

Among
Among the more eminent natives of this town, was Henry, turned name, de Huntingdon, from the place of his birth, a distinguished ecclesiastic and historian; who lived in the reigns of Henry III. and Edward I.; and wrote a history of the Saxon heptarchy, with accounts of the succeeding kings to the reign of Stephen. Richard Fritwiller, a gentleman, who has been already mentioned for his charities, was also a native. Huntingdon was likewise the birth-place of one of the most extraordinary characters that ever lived, the protector Oliver Cromwell, who, though prevented by considerations of policy from assuming the regal title, enjoyed all the essentials of sovereignty, and ruled this country with more than regal power. (See Cromwell.) Beauties of England and Wales, vol. vii.

Huntingdon, an extensive and mountainous county in Pennsylvania, bounded N. and N.W. by Lycoming county, E. and N.E. by Mifflin, S.E. by Franklin, S. and S.W. by Bedford and Somerset, and W. by Westmoreland. It is about 75 miles long, and 39 broad; comprehending 1,432,960 acres of land, divided into 18 townships, containing 36,968 inhabitants. In this county are found lime, iron, and lead. Works have been established for the manufacture of iron and lead.

Huntingdon, the capital of the above county, which is a poll-town, situated on the N.E. side of Juniata river, and at the mouth of Standing-Rime creek, 50 miles from the mouth of Juniata, and containing about 90 houses, a courthouse, gas, and 1251 inhabitants; 184 miles W.N.W. of Philadelphia. About six miles N.N.E. of the town is a mineral spring, celebrated for relieving rheumatism, and curing cutaneous disorders. N. lat. 40° 26'. W. long. 78° 2'.

Also, a poll-town on the N. side of Long Island, New York, at the head of a bay in Suffolk county, containing about 70 houses, a Presbyterian and an episcopal church; 35 miles E. by N. of New York city, containing 3602 inhabitants. Also, a poll-town in Fairfield county, Connecticut, containing 2792 inhabitants.

Huntingdon, North and South, two townships, in Westmoreland county, Pennsylvania, the former containing 1484, and the latter 2317 inhabitants.

Huntingdonshire, one of the inland counties of England, is bounded on the south-east and north-east sides by Cambridgeshire, on the north and west by Northamptonshire, and on the south-west by Bedfordshire. Its limits are chiefly artificial: the river Nene, the Northamptonshire border, with the King's Delf, the Old Well Water, and the Ufe river on the Cambridgeshire side, being the principal exceptions. The general form of this county is an irregular square; its extent, from north to south, is nearly thirty miles; its greatest breadth, from east to west, twenty-three; and its circumference about one hundred; its superficial contents have been estimated at from 220,000 to 240,000 acres. It contains four hundreds, six market towns, 107 parishes, 6076 houses, and 37,608 inhabitants, 52,572 males, and 10,027 females, according to the late returns made under the population and poor laws. It sends four members to parliament; two for the shire, and two for the town of Huntingdon. The government of this county is very peculiar; Cambridgeshire being joined to it under one sheriff, who is chosen out of that county one year, out of the shire of Ely the second year, and out of this county the third; and in the shire of Ely alternately out of the north and south parts. The whole of this county is in the diocese of Lincoln.

Ancient History.—Huntingdonshire, with the adjacent counties of Cambridge, Norfolk, and Suffolk, originally composed the territory of the Iceni; and in the Roman division of the kingdom was included in the district named Flavia Caesariensis. The principal Roman stations in Huntingdonshire, were Durobrivae at Huntingdon, and Durobriva, near Dorsford Ferry, about midway between Cheltenham in this county, and Caistor in Northamptonshire. The principal ancient roads, of which there appear to have been three, intersected each other near Huntingdon; one of them has been called the British Ermine. This seems to have entered the country from the vicinity of Caesar's camp, or Salems, in Bedfordshire, and to have proceeded by Cranford, in the track once known by the name of Hell lane, whence passing through Tofeland, Godmanchester, and Huntington, it continued by Acombury, Welford, and Upton; and entered Northamptonshire at Wardsford. The Roman Ermine Street came into this county from Cambridgeshire, near Papsworth St. Agnes, and proceeded to Godmanchester; branching off to the eastward, it crossed Northamptonshire, and entered Rutlandshire, near Stamford. The Via Devana, the third and last of these roads, entered this county from Cambridgeshire in the neighbourhood of Penny Stanton, and left it for Northamptonshire in the vicinity of Clifton. In the early Saxon times this district formed a part of the kingdom of East Anglia, and was then called Huntingtune, and Huntandune. It was afterwards conquered by the Mercian sovereigns, and continued under their dominion till the union of the Saxon states into one monarchy, by Egbert. In the decline of the Saxon government, Camden observes, "this county had an officiary earl, Siward; for earls were not yet hereditary in England, but the governors of shires were, according to the custom of that period, called earls, with the additional title of the shires they presided over: as this Siward, while governor here, was called earl of Huntingdon, but afterwards having the government of Northumberland conferred upon him, he was called earl of Northumberland." The principal land owners in this county in the Norman times, as recorded in the Doomeiday book, were the king, the bishops of Lincoln and Conlac; the abbots of Ely, Croyland, Ramsey, Thorney, and Peterborough; the countesses of Ely and Huntingdonshire, with her son; Judith, sheriff Ely, Alfred, Earl of Ely, Hugh, Walter Gifford, William de Warren, Hugh de Bolbec, Eudo Fitz-Hubert, Swain of Ely, Roger de Ivari, Arnulf de良好, Gilbert de Gaunt, Aubrey de Ver, Ralph Fitz-Omfund, and Rodlais, wife of Richard Fitz-Gilbert.

Surface, Fens, Soil, &c.—Huntingdonshire, Leland says, "in old time, was much more woody than it is now, and the deer refered to the fenes; it is full long fins it was deforsted." Camden corroborates this, and states, "that the inhabitants say it was once covered with woods; and it appears to have been a forest, till Henry II., in the beginning of his reign, deforested the whole, as fit by an old perambulation, except Waybridge, Sapple, and Herther, which were the lord's woods and remain forest." Sir Robert Cotton states that this country was not completely deforested till the time of Edward I., when that sovereign, in his twenty-ninth year, confirmed the great charter granted by Henry II., and left no more forest than his own demesne." This description of forest land cannot be supposed to apply to the fens, of which there are 44,000 acres in this county, exclusive of about 5000 acres of what are called skirry lands. These constitute nearly a seventh part of what is called the Great Bedfor Level, but they belong to that division called the Middle Level, and are principally found on the north and north-eastern parts of the county. About 8000 or 10,000 acres of the fen-lands are productive, yet the expense of keeping them from inundation amounts to almost one-third of the rents, through the imperfect state of the drainage. "It may
may seem paradoxical," says Mr. Maxwell, "that the fens of Huntingdonshire, whose surface is comparatively high, should be worse drained than those that lie between them and the fen, the surface of which is considerably lower; the natural supposition being, that water will inevitably fall from the higher to the lower level. But this is the case with all the fens that are upon the skirts of the high land, and proves only, that the general drainage was executed upon principles fundamentally wrong. The fact is, that there was not a proper outfall to the fen, at the time of the general undertaking to drain the fens, nearly a century and a half ago; and ingenious men employed themselves not in obtaining an outfall, as they ought to have done, but in constructing large drains, and high banks, within the boundaries of the fens, expecting the water would force its own passage, in spite of every impediment; though the distance between the fens and the fen was from ten to fifteen miles. This not proving to be the case, ingenuity was set to work, to invent engines for the purpose of throwing the water out of the lands into the internal rivers. Still it did not find its way to the fen, but overtopped the banks, or broke them down with the weight of its pressure; even to this moment, instead of retorting to the outfall, the engines have been increased in size, and the banks raised still higher, so that the water, which, if there had been an outfall, would have found its way to the fen, and left to itself, would have reaped on the lowest of the lands, has been forced in a retrograde motion, over the surface of the higher lands; and hence the deplorable state of the fens in Huntingdonshire." The slippery lands are those which border on the fens, and partake of the properties of mor, combined with whatever soil, whether clay, gravel, or loam, that may be prevalent in the adjacent uplands. These lands, in general, afford luxuriant grazing. The meadow lands, which are the next in order on the scale of elevation, consist of about twelve or fourteen hundred acres, bordering on the rivers Nene and Ouse, but chiefly on the latter. These are extremely productive, but the produce is frequently damaged by the floods, and the crops sometimes totally carried away; this chiefly happens along the banks of the Ouse from St. Neots to Erieh; and the numerous water-mills which are placed upon this stream increase the risk of damage. The fens in the upland parts of the country are various, but principally consist of a strong deep clay, more or less intermingled with loam, or of a deep gravelly soil, with loam. Of what are called the deep-flapped lands, great part is still in an open field state, where each particular occupier is necessarily obliged to pursue whatever course of tillage is practicable by the parish at large. The woodlands are but of considerable extent; and the country is thin of timber; this is attributed to the very great demand for it in the fens; and the upwood is sold at a higher price by the pole, than in most other countries. The high roads are in general pretty good; the crofs roads are but indiffident; and in the winter season many of them become impassable. No manufactures of note are carried on in this county, nor hardly anything that bears reference to them, except wool-dipping and spinning yarn; the latter is the chief business of the women and children in the winter season; in summer they seek a more profitable employ in the fields.

Results.—The principal rivers connected with Huntingdonshire, are the Ouse, and the Nene or Nen. The Ouse enters the county from Bedfordshire, and in its course towards Huntingdon is increased by a combination of small streams; having passed that town, it becomes the boundary between this county and Cambridgeshire, till it enters the Great Level of Fens near Erieh: this river is navigable along its whole line across the county. The Nene rises in Northamptonshire, and flowing through a delightful vale, reaches Huntingdonshire near Elton, where it becomes the boundary between both counties: afterwards winding to the east, it pursues a devious course to Peterborough, below which it winds into the Fens; and passes onward to the sea. Some smaller streams water the north-east side of this county, together with several large mere, or pools of water; namely, Whittlesea Mere, Ramsey Mere, Uff Mere, &c. of these, Whittlesea Mere is by far the largest, and is in the area of several miles, in extent; it affords excellent fishing and boating, and is in the summer season much frequented by parties of pleasure. "Most of the mere's are visited by abundance of wild-fowl." Maxwell's General View of the Agriculture of Huntingdonshire. Beauties of England vol. vii.

HUNTINGTON, Robert, in Bibliography, an English divine, was born at Deerve, in Gloucestershire, in 1636, and educated at Drifit, from whence he was removed to Merton college, Oxford, of which he became fellow. In 1662-3, he was admitted to the degree of M. A.; after this he applied himself most diligently to the study of divinity and the oriental languages. In 1670 he was appointed chaplain to the factory of Aleppo, where he improved himself in the oriental languages, and collected many curious manuscripts. Having carefully visited almost the whole of Greece and Asia Minor, and examined the various customs, and religious books, he went to Jerusalem, from whence he embarked for Cyprus, for the purpose of examining the library of Hilarion Cigals, the primate of the island, but on his arrival at Cyprus he found the prelate had been obliged to flee his safety from the Turks in flight. In the following year he undertook the difficult journey of 150 miles to view the ruins of Palmyra, which he was prevented from examining, and was himself in considerable danger of his life from two Arab chiefs, who had taken possession of that district. He next went to Egypt, and continued during his whole residence in the East to improve himself, and benefit his country and the world, by rescuing from oblivion curious copies of the Gospels, and other books relating to polite literature. In the year 1682 he set out on his return home, and visited in his journey Rome, Naples, and other most considerable places in Italy. From Italy he went to Paris, whence he arrived safe in England, and was almost immediately after his return, raised to the degree of D. D., and at the same time appointed master of Trinity college, Dublin. This promotion he very much disliked, regarding it as a kind of punishment; but he was persuaded by his friends to undertake the duties attaching to the office, which he performed very much to the benefit of the institution, and to the interests of literature in general. In 1691 he returned to England, resigned his master, and removed never more to quit his country. He made a present to the Bodleian library of many valuable MSS., the curators of which purchased his others, to the number of about 600, for the sum of 700. In the following year he was presented to the rectory of Great Hallingbury, in Essex. About the same time he was offered the bishopric of Kilmore and Ardagh, in Ireland, which he refused; but in 1701, notwithstanding his former determinations, he accepted the bishopric of Rapho, in that kingdom. He survived his consecration but a few days, and died in the forty-sixth year of his age. Some of his observations are in Ray's Collection of Voyages and Travels; and in the Philosophical Transactions he gave an "Account of the Porphyry Pillars of Egypt." Biog. Brit.

Huntington, in Geography, a port-town in Chittenden county, Vermont, on the S. side of Onion river, 15 miles N. E. of Burlington, containing 450 inhabitants.
HUNTYL, a town of Transylvania, on a small river, which runs into the Maros; 54 miles E. N. E. of Temesvar. N. lat. 45° 31'; E. long. 22° 44'.

HUPPOOAH, a town of Bengal; 47 miles N. W. of Ramgur.

HURA, in Botany, a name of barbarous origin, but, contrary to his usual practice, adopted by Linnaeus. It appears to be the name of the tree in question among the inhabitants of Guiana, as, at professor Martyn reports, of Mexico, where it is said, in Hernandez, to be distinguished by the Equipedalian appellation of Quandbotlatunum, which, it seems, means a cracking tree. Linn. Gen. 504.

HUNTSBURG, 25 miles S. E. of Boghipour.

HURCHUNCHUCK, in Geography, a town of Bengal; 25 miles E. S. E. of Boghipour.

HURCHUNDY, a town of Bengal; 10 miles S. of Chipamy.

HURCHURNPOR, a town of Bengal; 17 miles N. of Rajamal.

HURCOS, or Urcaes, in the diocese of Cufco; 21 miles S. of Cufco.

HURDAH, a town of Hindooftan, in the Candieh country, on the S. of the Nerbuiddah river; 22 miles S. E. of Hindoo. N. lat. 22° 23'; E. long. 77° 19' 45'.

HURDES, or Hards, of flax or hemp, the coarser parts, separated in the dressings from the hair or fine fluff. See Hemp and Flax.

HUDLE is the name of the fledge used to draw traitors to the place of execution.

HUR, in Agriculture, the name of a light wooden frame, formed of small bars, or otherwise, somewhat in appearance similar to the low common field gate. It is principally employed for the purpose of constituting a sort of movable fence for inclosing and confining sheep, and other kinds of live Rock, during the time they are consuming some fort.
fort of rich green, or other luxuriant food. The usual materials for the forming of hurdles are those of some fort of light split wood, or hazel rods of rather young growth. In the former case they are commonly put together by means of framing or nailing, and in the latter by wattling the rods in between a fort of small flakes. Hence they are often denominated framed or wattled hurdles by way of distinction.

Besides the above uses, hurdles are necessary in folding sheep on arable lands, and also in feeding off turnips, either by them or next cattle, on the land, in order to keep them upon a certain space of ground, and thus afford them a limited portion of food at a time, by which a considerable saving is effected in its being eaten up more cleanly and with less waste, than would be the case if they ranged over the whole. And on the tillage lands the sheep, by being so closely confined, contribute in a very high degree to its fertility and improvement.

It has been lately observed, that "in the grazing of a large field, for instance, when the sheep or cattle are turned upon it early in the spring, they tread down and destroy a great deal of the grass; and by dropping their dung and urine upon the remainder, injure it so much as to render it unpalatable to the flock. In this way a great proportion of the grass is lost in every field of considerable extent; whereas when the flock is first put upon the field, if hurdles or flakes were run across a small part of it, as is the case with turnips, and the grazing flock kept there till they had eaten the herbage clean up, they would then, from necessity, eat a great deal that is entirely lost, when they are permitted to range over the whole field. In this way considerably more flock might be fed upon a given space, than is done at present. It is to be observed, however, that the first space divided off by the flakes should be next the water, especially if the field is grazed by black cattle or horses, and that progressively, as the flock is removed from the watering place, a lane should be left, by which the cattle may travel to the pond. It is also to be noticed, that after the first space allowed to the grazing flock is eaten clean up, and as soon as they are shifted to a new place, a course of flakes should be placed behind them, to prevent them from going backward upon the pasture that has been already eaten bare. By this management the whole of the herbage, upon every space allotted to the flock, will not only be completely eaten up, but, by dividing or fencing off that part which has been eaten, the plants are allowed to recover; and, long before the whole field is gone over, the space first eaten will be in a situation to receive the flock a second time. By this method the dung and urine of the flock, instead of rendering the herbage nauseous and unpalatable, and thereby preventing them from eating it, will, by its fertilizing powers, afford its growth, and render it fitter for being eaten a second time, and by that means afford three or four crops in the space of a year instead of one. Experience has sufficiently evinced the great profit and advantage that attend the practice of treading cattle or horses upon good pasture, or of feeding them in the house with cut grass. The benefit in both these cases arises from the whole of the herbage being completely eaten up, without any part of it being lost. The fame benefit, but with infinitely less trouble, may be reaped from hurlding or flaking grass fields: every possible advantage will be made of them in this way; and in very many instances it will happen, that before a half or two-thirds of the field are gone over by flaking, the part first eaten will be in a situation again to receive the flock. By that means it is a part of the field may be faved for hay; or, if the views of the occupier be of another kind, the number of the grazing flock may be increased in a proper degree.

The writer is "aware, however, that it may, and no doubt will be argued by many, that this management will be attended with much trouble and expense; and after all, that the profit resulting therefrom will be but small, and fearfully prove equivalent to the trouble and extra expense. From the acknowledged value of hurlding, however, in the consummation of turnips, cabbages, &c., and the great profit which arises from giving the flock only a certain quantity of food at once, and withholding any more from them till that is eaten up, some idea may be formed of the vast advantage that would attend the flaking of a grazings flock in different cases. He by no means, however, wishes these observations to be understood as applying to grasing pastures of every description; quite the contrary, as there are many situations where the expense and trouble of flaking would prove more than an equivalent for any advantage that could be reaped from the practice. But upon all rich pastures, the benefit arising from the practice of flaking will be found very considerable, and a single experiment will be sufficient to convince the most incredulous."

It is obvious that in parks, pleasure-grounds, and other ornamented places, the eating of the grases may be the most conveniently and economically accomplished by means of hurdles, as, in this way, the danger of injuring the trees and shrubs is most effectually prevented; and from the hurdles being capable of a ready removal, any portion can at pleasure be eaten down in the most definable manner.

In regard to the expense of hurdles, those of the framed kind are usually from about 12s. to 18s. or 20s. the dozen, according to the manner of making them, and the nature of the wood employed. The wattled fort are commonly much cheaper, being sold rather higher than from 10s. to 12s. the dozen. A representation of a framed hurdle is given in the plates on fences. See FENCE.

It is found from actual trials, that a dozen and a half are sufficient for folding thirty sheep; and that about twelve dozen will answer the purpose for one thousand in most cases.

HURDLE, lamb, the title of another fort of hurdle, constructed for the purpose of protecting and preferring lambs soon after they have been dropped, and while they continue in a weakly state. It is suggested in the survey of Lincolnshire, that "vigilance in the lambing season prevents much of the danger in bad weather, but that in addition," a provision against the loss of lambs in the ditches of the breeding pastures, has there been made at a small expence, by means of lamb-hurdles.

These are constructed of two thin rails, with heads at the ends and proper braces; the space between the rails being closed in by having tarpauling nailed securely to each of the rails, &c. But it is hinted, that "as the tarpauling would require many nails, and as canvas is a dear article," the space may perhaps be better filled, by a flit deal held in place by having braces on both sides, one of which might be moveable, and fix with nuts on the rivets, by which means the board might be put in only occasionally when wanted. This description of hurdle is represented in the plates on fences. See FENCE.

It is further noticed, that this hurdle, "when the lower rail touches the ground, is a perfect defence against the wind, and of a sufficient height to prevent the limbs driving before a storm into the ditches; so that it answers two good purposes." And that, "at other fencings also, these hurdles may come into use for guarding the brows of banks against sheep.
HURDLES, in Fortification, twigs of willows or osiers, interwoven close together, in the form of a long square, five or six feet long, and three or three and a half broad, interlaced by strong flake, and usually lade with earth. Hurdles, called also clapes, serve to render batteries firm, to confound the passage over muddy ditches, and cover traverses and lodgmenits, for the defence of the workmen against the artificial fires or fiones that may be call upon them.

HURDLING, a term signifying the art or practice of dividing land by the use of hurdles, in the view of improving the grounds or confining the food with greater economy and advantage, by the confining of different forts of live stock, within certain limits. It is a highly beneficial method of management in a great number of infancies. See FOLDING OF SHEEP, and HURDLES.

HURDS, in Rural Economy, a name given to the coarser parts of flax and hemp, which in the dressing of them are separated from those of the fine fluff of either of such matters.

HURDWAR, in Geography, a town of Hindoostan, in the northern part of the country of Delhi, on the Himmal. near the W. coast of the Ganges, where it enters the plains of Hindoostan, on the borders of Tribet; 86 miles N. of Delhi. N. lat. 29° 55'. E. long. 78° 23'. See GANGES.

HURDY-GURDY. See MONOCHORD.

HURE', CHIRELS, in Biography, an eminent French divine, was son of a labourer at Champigny-lur-Yone, where he was born in the year 1639. As he shewed a strong inclination for learning, his father caused him to have a good education, and obtained for him a fitness to the archbishop of Sens, who gave him an exhibition in the college des Graffins at Paris, where he distinguished himself greatly among his contemporaries. Having completed his academical studies, he was admitted into holy orders, and appointed one of the preachers of his college. He was afterwards made professor of the belles lettres; and at length became principal of the college of Boncourt, where he died in 1717, in the seventieth year of his age. His principal works are, "A Dictionary of the Bible," in two volumes folio. "A Translation of the New Testament into the French Language with Notes," and "A Sacred Grammar," intended to illustrate the New Testament. He was a man of great simplicity of manners, who united to much candour, ardent piety and a solid judgment. Moret.

HURREEPOUR, in Geography, a town of Hindoostan, in Lahore; 95 miles E.N.E. of Lahore. N. lat. 32° 5'. E. long. 75° 42'.

HURENHUTTERS, in Ecclesiastical History. See HERENHUTTERS.

HURFWA, in Geography, a town of Sweden, in the province of Skone; 10 miles N.E. of Lund.

HURIEL, a town of France, in the department of the Allier, and chief place of a canton, in the district of Montluçon; six miles N.W. of it. The place contains 1628, and the canton 10,178 inhabitants, on a territory of 400 kilometres, in 16 communes.

HURKUTTA, a town of Bengal; 40 miles S.E. of Curruckdeah.

HURLE Bone, in a horse, is a bone near the middle of the buttock; very apt to go out of its sockets with a flip or strain.

HURLERS, a number of large flones, set in a kind of square figure near St. Clare, in Cornwall, so called from an old opinion held by the common people, that they are fo many men petrified, or changed into flones, for profaning the Sabbath-day by hurling the ball, an exercise for which the people of that country have always been famous.

The hurlers are oblong, rude, and unhewn. Many authors suppose them to have been trophies erected in memory of some battle; others take them for boundaries to districtish-ghul lands. Lastly, others, with more probability, hold them to have been sepulchral monuments.

HURLEY, in Geography, a township of America; in Ulster county, New York; containing 1159 inhabitants.

HURLOCK, in Mining, signifies the harder beds of chalk in the lower parts of the series N. of Dunstable, which is principally used for burning lime, for mortar-making in that district, for the use of lime in agriculture is there almost unknown. The hurlock is without layers of flints, and contains very minute grains of silex distributed through its mass; some large corns amonials and others of an oval figure, according to Mr. Parkinson, and other shells are found in it; the lower beds are mostly diluteous, and they terminate below in the Pottemhoe freestone, of which Woburn abbey, the Swan Inn at Bedford, and many other good houses are built; this, at the foot of the North Downs, near Ryegate, Goodfane, &c. is a flint; at the foot of the South Downs in a similar situation it has not been discovered, because not fought after, we believe.

HURLY-BURLY, in Vulgar Language, denotes confusion, or tumult, and is said to owe its origin to two neighbouring families, Hurleigh and Burleigh, which filled their part of the kingdom with content and violence. Johnson.

HURON, in Geography, one of the five principal lakes of North America; lying between 43° 30', and 47° 30' N. lat. and between 80° 45' and 84° 45' W. long., and reckoned upwards of 1000 miles in circumference. The fifth of this lake are similar to those of Lake Superior, with which it communicates by the straits of St. Mary, about 40 miles in length, and in some places only one or two miles in breadth, with a rapid towards the N.E. extremity, which may however be defended by canoes, and the prospects are here delightful. Another short strait leads into the lake called Michigan, and it communicates with lake Erie on the S. It is of a triangular shape; and on the S.W. part is Saginum or Sagana bay, 80 miles long and about 18 or 20 broad. The other most remarkable bay is Thunder bay. On the banks of the lake are found great quantities of small cherries. The land on the western shore is much inferior in quality to that on lake Erie. It is mixed with sand and small flones, and is covered chiefly with pines, birch, and some oaks; but at a little distance from the lake the soil is very luxuriant. Some few years ago, a part of the Indian nations, called Chepaways and Ottawas, who inhabited round Sanguinum bay, and on the banks of the lake, could furnish 200 warriors; and those of the latter nation, who lived on the E. side of lake Michigan, 24 miles from Michilimackinack, could furnish 200 warriors. Those who lived on the E. side were called Hurons.—Alfo, a small river of the north-west territory, which, after a course of 35 miles, falls into lake St. Clair from the N.W.—Alfo, another small river in the same territory, which runs north-eastward into lake Erie; 40 miles southwest of Cayahoga, and 15 S.E. of the mouth of Sandufky lake.

HORUNG, a town of Bengal; 35 miles S.S.E. of Islamabad.

HURPEYA, a town of Hindoostan, in Moulton; six miles N.W. of Shawanaz.

HURPLE, in Rural Economy, a term applied in many places to cattle, when they set up their backs in the cold severe winter leason.

Z. HURPOIS,
The one that happened Aug. 31, 1722, was very terrible and destructive, it extended 500 leagues or upwards.

Few people of scientific observation have had opportunities of marking the phenomena which attend these West Indian hurricanes. A writer, giving an Account of the European Settlements in America, observes, "It is in the rainy season, principally in the month of August, more rarely in July and September, that they are assailed by hurricanes, the most terrible calamity to which they are subject from the climate. This destroys at once the labour of many years, and frustrates the most exalted hopes of the planter, and often just at the moment when he thinks himself out of the reach of fortune. It is a sudden and violent storm of wind, rain, thunder, and lightning, attended with a furious whirling of the sea, and sometimes with an earthquake; in short, with every circumstance which the elements can assemble that is terrible and destructive. First they see as a prelude to the ensuing havoc, whole fields of sugar-canes whirled into the air, and scattered over the face of the country. The strongest trees of the forest are torn up by the roots and driven about like rubble. Their wind-mills are swept away in a moment. Their works, their fixtures, the ponderous copper-boilers and hogs of several hundred weight, are wrenched from the ground and battered to pieces. Their houses are no protection, the roofs are torn off at one blast, with the rain, which in an hour rife five feet, rushes in upon them with an irresistible violence. There are signs which the Indians of these islands taught our planters, by which they can prognosticate the approach of a hurricane. It comes on either in the quarters or at the full or change of the moon. If it will come on at the full moon, you being at the change, observe these signs. That day you will see the sky very turbulent. You will observe the sun more red than at other times. You will perceive a dead calm, and the hills clear of all those clouds and mists which usually hang about them. In the crumps of the earth, and in the wells, you will hear a hollow rumbling sound like the rushing of a great wind. At night the stars seem much larger than usual, and surrounded with a fort of burs. The north-west sky has a black and menacing look, and the sea emits a strong smell and ripples into vast waves, often without any wind. The wind itself now forfakes its usual steady eastern stream, and shifts about to the west, from whence it sometimes blows with intermitting violence and irregularly for about two hours at a time. You have the same signs at the full of the moon. The moon itself is surrounded with a great bust, and sometimes the sun has the same appearance." Another author, Captain Langford, (see Philos. Trans. abridged, vol ii. p 165.) makes the following observations among others: "It is to be observed, that all hurricanes begin from the N. to the westward, and on those points that the easterly wind doth most violently blow, both the hurricane blow melt fiercely against it; for from the N. E. to the E. S. E. the easterly wind bloweth freshest, so doth the W. N. W. to the S. S. W. in the hurricane blow most violent, and when it comes back to the S. E. which is the common course of the trade-wind, then it ceaseth of its violence and so breaks up.

Though hurricanes may be deemed extraordinary events, and therefore may be ascribed to the operations of extraordinary causes, it is more probable that they arise principally from the ordinary causes of wind, which are the unequal temperature of the earth's surface in the different parallels of latitude, or rather of the incumbent atmosphere, and the diurnal rotation of the earth; to which may be occasionally added the precipitation of uncommon quantities of rain, accompanied with thunder and lightning. See Wind.

It has been the custom of late times to assign electricity as the cause of every inexplicable phenomenon in meteorology. Not only hurricanes but winds in general have been referred to electricity as their cause; but it will be time enough to introduce this cause when the common principles of the mechanical philosophy have been fairly applied and found inadequate to the explication.

Weips is subject to very violent hurricanes, which do great mischief, and that in a very singular manner. Thunder and lightning are frequent with them in winter as well as in summer; and the more violent storms of these are sometimes attended with whirlwinds and hurricanes, which will raise the waters of some lakes in form of a thick pillar up to the clouds, and carrying on before the wind this watery mass of water, will sometimes fall on other places on dry land, and drown the houses and gardens where it chances to fall.

HURRIERS, in Mining, are those persons employed in a coal- pit, who hurry or drag the curves of coals from the banks where they are dug to the bottom of the winding shaft to be drawn up.

HURRIES, in Engineering, is sometimes applied, at Newcastle and other places, to the strong flanges of wood erected by the sides of the navigable rivers and harbours, on to which the rail- ways are conducted from the coal- pits; by which means the load is at once emptied, by help of a spout, from the rail- way wagons into the holds of the ships. See STATEN.
HURRY, in Agriculture, a term often applied in the south-western and other districts of the kingdom, to a small load of corn or hay.

HURRYAL, in Geography, a town of Bengal; 20 miles S.E. of Nattore. N. lat. 24° 18'. E. long. 89° 28'.

HURRYPOUR, a town of Hindooftan, in Soore; 17 miles S. of Ranny Bednore.

HURSYALOO, a town of Hindooftan, in the ciearc of Nagore; 12 miles W. of Cutchwana.

HURST, or Hyst, in our Old Writers, denotes a wood or grove of trees. Hence such places as have this word for part of their names, have been situated near a wood. In Kent, Suffolk, and Hampshire, there are many such, because formerly the great wood called Anderwald extended itself through these counties.

HUTER, in Artillery, a flattered iron fixed against the body of an axe-tree, with tramps to take off the friction of the naves of wheels against the body.

HUTERS, in Fortification, denote pieces of timber about six inches square, placed at the lower end of the plat-form, next to the parapet, to prevent the wheels of the gun-carriages from damaging the parapet.

HURTS, in Heraldry, by some wrote Hearts, and by others Hurtz, are azure or blue rundles.

The English heralds distinguish between the colours of rundles, and give them different names agreeable thereto: those of other nations content themselves to call those tereaux d'azur; and in other cafes only add the descriptive colour to the term tereaux.

But thet being blue, some will have them to signify bruises or contusions in the flesh, which often turn to that colour: others suppose them whisttle berries.

HUS, or Huzz, in Geography, a town of European Turkey, in the province of Bithynia, the see of a Greek bishop, situated on the Pruth; 70 miles S.W. of Bender.

N. lat. 46° 34'. E. long. 28° 34'.

HUSACKER, one of the small Shetland islands between Mainland and Yell. N. lat. 60° 48'. W. long. 1° 35'.

HUSBAND, MARTUS, a man joined or contracted with a woman in marriage. See COUPEUR and MARRIAGE.

See also DIVorce, Dower, Feene-Covert, &c.

HUSBAND Land, a term used in Scotland for a portion of land containing fixed acres (= 7,624 1/2 English statute acres) of fock and fcythe land; that is, of land that may be tilled with a plough, and mown with a yythe.

HUSBDANDMAN, in Agricultura, the common name of the labourer or person who is engaged in the tillage and cultivation of the soil. It has been, in general, too much the practice to despise and deprese the habits and talents of this most valuable class of society; as by such means the necessary ardour and spirit of exertion are much abated, and the improvement of husbandry greatly retarded.

The ingenious author of the "Wealth of Nations" has drawn the following curious and interesting comparison between this sort of labourer, and the artisan or mechanic. He says, that "not only the art of the farmer, the general direction of the operations of husbandry, but many inferior branches of labour require much more skill and experience than the greater part of mechanic trades. The man who works upon braies and iron works with instruments, and upon materials of which the temper is always the same, or very nearly the same; but the man who ploughs the ground with a team of horses or oxen, works with instruments of which the condition is of different kinds. The differences in the materials which he works upon, too, are as variable as that of the instruments he works with, and both require to be managed with great judgment and discretion. The common ploughman, though generally regarded as the pattern of stupidity and ignorance, is seldom defective in his judgment and discretion: he is less accustomed, indeed, to social intercourse than the mechanic who works in town. His voice and language are more uncouth and more difficult to be understood by those who are not used to them. His understanding, however, being accustomed to consider a greater variety of objects, is generally much superior to that of the other, whose whole attention, from morning to night, is commonly occupied in performing one or two simple operations. How much the lower ranks of people in the country are really superior to thef of the town is well known by every man, whom either busines or curiosity have led to converse much with both. In China and Hindooftan, accordingly, both the ranks and the wages of country labourers are paid to be superior to those of the greater part of artificers and manufacturers. They would probably be fo every where, if corporation laws and the corporation spirit did not prevent it."

There can be no doubt of the vast utility and national advantage of promoting the spirit, and encouraging the exertions of the labourers in agriculture; as, however high the benefits of commerce may be estimated, it is only the raising of the necessary food for the support of the population of a nation within itself, that can render it truly great, happy, and independent.

HUSBANDRY, a general name applied to the art, busines, or employment of the farmer, or of those engaged in the tillage and cultivation of the soil. There are various descriptions of husbandry depending on the particular views of the cultivator, and the methods of management which are adopted.

Hence, in regard to tillage or arable lands, there are the broad-cast and drill-husbandry, and it is often further divided by the way of diffusion into what are termed the old and new husbandry; the former of which is supposed to be that which has been had recourse to from the most early periods; and the latter that which has been faved to have been introduced and inculcated by the intelligent Mr. Tull and his followers. This last is likewise occasionally distinguished by the title of the broad-hoing husbandry. But though this husbandry be generally denominated new in this country, there is reason to believe that it is not fo modern as has been commonly suppos'd, as it has been aperceived that in many of the eastern nations, where few, if any, changes in their agricultural practices have occurred for many ages, it is for most sorts of crops the most usual mode. See HUSBANDRY.

It may be further noticed here, that the broad-cast husbandry is that kind of arable management in which the seed is thrown and dispersed over the ground by a fort of cast of the hand, without much regard being paid to the regularity of the crop, or the means of its after-culture. Besides, it is suppos'd by some farmers, that in this mode much less preparation of the land was necessary, but the contrary has been fully proved by later and more extensive experience.

And the drill-husbandry is that in which the grain or other kinds of crops are sown, set, or put into the soil, in rows, drills, or trenchers, at different distances, by tools and machines contriv'd for the purpose, in order to be cultivated afterwards with implements particularly fitt'd to them. In this way the seed is put into the soil with much more regularity and exactness, both in respect to evenness and depth, as well as the after-culture performed with much greater correctness and attention by the use of proper hoes and harrow labour.
HUSBANDRY.

In cases where either of these modes is exactly followed, but there is a kind of mixture of them both; or where two forts of crops of different descriptions are cultivated together, in alternate rows, there is what has been frequently denominated half-husbandry: and where the ground is cultivated alternately in tillage and grass, there is that fort which is usually called convertible husbandry by modern farmers.

There are also particular methods of cultivation adopted on extensive tracts of ground in the state of commonage, which afford what is frequently denominated common-field husbandry.

With respect to lands in the state of grass, there are likewise dairy, grazing, and grass husbandry, according as the grounds are appropriated to the keeping of cows for milk, butter, or cheese, the feeding or fattening of different sorts of live-flock, and the making of grass into hay to be used as fodder.

The culture of particular sorts of crops also gives rise to different terms of this nature; hence there is turnip, cabbage, carrot, and potato husbandry, &c.

In those different points of view, husbandry, of course, comprises the whole of the numerous operations, proceesses, and modes of management which are necessary in the extensive businets of cultivation, either in regard to tillage or grass, or the breeding, rearing, and keeping all sorts of live flock of the domestic kind.

It is sufficiently evident, that very great improvements have been accomplished in the various branches of husbandry within these few late years by the introduction of more correct and better modes of cropping and managing lands, as well as by the gradual influence and adoption of better and more suitable tools and machines for executing the busines of the farmer.

A late writer has laid down the following comparative estimates of the difference in the advantage between an acre of land cultivated under the old plan of fallowing once in every three years, or two crops and a fallow, which is supposed not to run out or exhaust the ground; and that of the more modern system of alternating green, or fothering crops, with those of the grain kind.

Carry over 7 18 6

Hence it would appear that the expences of the new method of husbandry are not only less by eight shillings the acre than those of the old the first five years, but will somewhat decrease in the next fix, except in manure, which will be more, as in the new mode the refervoir and five crops of straw will, it is suppos'd, produce nearly double the quantity. Besides, in the first way, the manure is all raised from the produce of the land it is laid on; but to make the twelve loads, the old farmer robs the meadow, or any piece of fresh land he is permitted to plough up. This is suppos'd the principal cause why so many tenants are restric'd from ploughing old swards, as they do not return the manure to its proper situation, or lay it on in such a manner as is proper.

Balance in favour of the new system 8 5 6

9
**Husbandry.**

In all these estimates it is supposed that every acre of straw, where the crop is a good one, is capable of affording two loads of manure; consequently, by the old plan, even admitting the crop to be good, which is often not the case, there would be only eight loads of manure raised in six years; but, by the new, 10 loads, even without the assistance of the reforward; and in the following six years, where the new system is pursued, 14 loads may be expected. In these statements the manure is charged as an expense, which is not right, where it is not purchased but raised on the ground.

If these calculations can be depended upon, there can be no doubt of the great superiority of the green-crop practice over that of the fallow method.

Other statements, by the same writer, on the differences of these different systems of management, on farms of different kinds, render the matter still more obvious.

It is imagined that the whole of the houses, barns, buildings, and fences of the farm may occupy nine acres, which will leave 10 acres for the keep of the cows, horses, &c. To answer which purpose they are advised to be cropped in this way: three acres and a half with winter tares; two and a half with summer cabbages, and potatoes under them; and the four that remain with spring tares, or a part of them with buck-wheat. These 10 acres are to supply the place of the 59s. allowed for the same use under the old plan, constantly furnishing the farm buildings to occupy the quantity above stated. These 10 acres must necessarily do something in cultivating; but when well managed, they will, if it is supposed, keep 40 head of neat cattle and horses in summer with cut straw; and the farmer will thereby have 150 acres of straw, clover, &c., where he had, under the old mode, only 59s.; besides, the crops will be much more bulky, and the quantity of manure constantly increase by the keeping so many cattle, horses and pigs in the yards, summer and winter; and as the food that is advised is too rich for breeding flock where six cows are kept, as already noticed, 26 feeding beasts will be also wanted, which may afford an average profit of five guineas each, though more may be produced; as two returns may be made. But as these profits may be doubled by loan, they are explained more fully by a debtor and creditor account; and the 10 are supposed to be set with potatoes at first, to clean and prepare the land for the tares, &c. carrying the profit on them to the general account, as being part of the crop of the first year of the improved husbandry.

### Under Potatoes 10 Acres.

It is supposed that in this case the potatoe crop is sown upon the land, as it is not easy to estimate the expenses when the potatoes are disposed of at the market, or double the sum allotted would be made of them; as 100 sacks, at 3s. each, would afford 15l. the acre, or 150l. in the whole; but if they were properly cultivated there would be 150 sacks to the acre.

Cr. by Produce. £ s. d.

By the profit of 32 beats, at an average of 5l. 5s. per beat - - - 168 0 0

Profit by this mode - - - 140 1 6

It is noticed that this return of profit seems great, but arises from the vail supply of food that is afforded by the 10 acres of land under tares and rye, when combined with cut straw in the keeping of live flock. As 10 horses have been found capable of being kept on the 3 acres of wheat-scourge, and the same extent of oats, it may be readily conceived that 10 acres of green fodder, in connection with the same number in wheat for straw, will keep 40 head of neat cattle and horses for the summer; consequently, 40 acres of wheat, 20 acres of clover twice mown, 20 acres of barley-straw, and 20 acres of pea-straw, in combination with the 20 acres of turnips, will keep with facility 32 head of beast, and eight horses, through the winter season. It is evident, therefore, that the produce of the 10 acres in green food, in connection with the straw and clover of the other portions, will, under proper management, accomplish what has been flated.

It may be added, that cabbages of the early kind will be ready to cut early in June, and may be kept in store all the summer, as, before one portion is cut over, the sprouts of another will be in a state to cut again. These cabbages should be given to such beasts as are the nearest ready for the market. As soon as the winter tares and rye have been consumed, Savoy cabbages should be put in the same. The tares will be mown in summer, and the cabbages will serve the cattle in winter, and be soon enough off the ground to feed it with tares in the spring. The land where the spring-cabbages have grown should be sown with winter-tares, in the drill method, in the autumn, using from four to six loads of dung to the acre for each crop. In the manner of the garden, therefore, these 10 acres are to be constantly covered with crops, for the use of neat cattle and other parts of live flock.

Though 20 acres have been put down for turnips, to be employed in feeding neat cattle in the yard, the whole will not by any means be wanted, so that one-half, or perhaps more, may often be converted to the use of the sheep, and in that way a profit be afforded, which has not been taken into the account. Besides, the quantity of manure flated under the improved husbandry is much less than will be produced.

But allowing, under the improved practice, an additional man and boy to look after the live flock, the former, at the expense of 12s. a-week, and the latter at 6s. per week; rejecting the fractional parts, and taking 52 weeks for the year, there will be 46l. 16s. to deduct, which will leave the balance of 42l. 14s. Thus the profit by the old method being 150l. 8s. 6d. which, taken from the 46l. 14s. leaves the net balance of profit in favour of the improved husbandry to be 275l. 5s. 6d.

On the old plan, the profit of a horse in two years was estimated at 16l. which, taken for one year only, or one half, is 8l. and for pigs 5l. as already flated, which sums, added to 275l. 5s. 6d. make, in the whole, 288l. 5s. 6d. and the 8s. for the potatoes being only brought to the account, though the net profit from the 10 acres, in green crops, is 140l. 16s. 6d. the aggregate sum will be 348l. 7s. which seems a large amount.

But, in this improved management in tillage and live stock, manure is raised to fo much better quality, in such plenty, and at fo much cheaper a rate, than by purchasing it, as is the general custom of the vicinity of the farm, that it is hardly worth stating from the large towns; and as it is the very soul of husbandry, every crop will be raised in far greater abundance.

It is however remarked, in conclusion, that there are different advantages, in regard to situation, that attend this farm, which, from their local nature, will not apply to those afterwards noticed. It may be supposed that the profit on the beats is laid too high; for though, when cattle are fed on grasses, the feason may possibly vary so much that double the quantity of flock may be carried at one time to what the same land is capable of at another; of course, as it is common to put on the same number of cattle every year, it may, in some dry periods, be much overloaded with flock, while in others, which are more moit, there may be a deficiency, under either of which circumstances there must be losses sustained; but where food is provided in the way just flated, the green-crops mostly become so forward before the dry weather occurs, that they are not injured by it, and the flock, where properly chifton, by the use of the fold or stall-feeding, with certainty becomes quickly fat. Every thing is in this mode daily regular, and the animals daily increase to the profit of their owners. Advantages are afforded, in different ways, by the contiguity of markets, as in the sale of, and jobbing in neat cattle, horses, &c. and likewise in the strength of the teams that may be necessary.

It may be noticed, that, in these estimates, it is supposed that all the ploughing, fowing, and leading should be had and paid for. As the accounts are drawn out, they of course incline much in favour of the old plan of husbandry, as the expenses are less in number than will be actually incurred in that way, being made for the purpose of exhibiting at one view the vail disparity which is really found to exist in the practice of the two different modes on farms of a similar description. That the profits can be ascertained with exactness is probably impossible, in consequence of the great fluctuation of markets, by which no person can be exact in the estimates of the value of corn or cattle for the space of six months together. The expenses have, however, been constantly estimated at a higher rate than it is known they can be done for, that the old method of husbandry might not be supposed to be unfairly dealt with.

These estimates of profits, whether they rest upon the basis of experience or not, sufficiently point out, that vast benefits may be drawn from the culture of green and other cattle crops, and the conversion of them to the feeding and fattening of various kinds of domestic animals.

II. A Mixed or Grazing, Breeding, and Tillage-Farm.

Extent 314 Acres.—It is situated in the county of Lincoln.

The estimates here display the benefits of different modes of management, where several kinds of husbandry are carried on in combination.

At present part of the farm is divided into four divisions for the plough, each division consisting of twenty-four acres. And there is an additional division of the same kind, comprising sixteen acres, and about fourteen acres of clay land, which is also under the plough. The four large divisions, and that of sixteen acres, are on a lime-stone fall, but the remainder on clay, and liable to rot sheep. These together make 126 acres, all under the plough on the old plan. There is of course remaining 188 acres, which are wholly in grass, and converted to the purpose of raising 140 lambs, or turning 110 ewes, the hog sheep being sold off in the spring, and the drape ewes at Michaelmas, and the support-
Husbandry.

ing of twelve horses and thirty head of beasts. The manner of cropping is that of the old method, of turnips, barley, clover, and wheat, which perhaps is as good as any, the farm being converted to the breeding of sheep, which is highly lucrative.

The expences and produce are thus stated.

Annual Mode of Husbandry, under the old System.

### Vol. XVIII.

314 Acres.

which is conceived the most beneficial mode of keeping them, and beyond comparison preferable to letting them run over the grases, if it were only for the advantage of the manure, which is extremely valuable to the land.

It is hinted, that on such a farm, at least forty head of

3 A neat
HU83BANDRY.

heat cattle and horses should be kept, winter and summer, in the yards and stables, but twice that number might be had; which, by the use of the green food, would furnish a vast supply of good manure, far better than such as is railed in the usual way during the winter season. And by blending the straw with the green fodder, it may be eaten up with much more profit than in the usual way; while the flock are kept in far better condition.

It is believed that the evil of the land rots the sheep flock is remedied by the conversion of the eighty-four acres of clay land into tillage, and the custom of eating off the feeds, faimforder, edin, &c. The horses may be fouled in the fields and yards, to avoid the injury of poaching, and thereby those of them be kept up.

And as the flock of sheep is increased by seventy, provided the statement be accurate, in the place of telling the hog-sheep, they may be kept for weathers. However, if danger from rot be apprehended, the cattle flock may be augmented, and be probably as profitable; the old number of sheep (200) being only retained to clip; the feeds on the twenty-four acres, part of the ninety-six estimated to keep five sheep per acre, by being sown with grass seeds, in the spring, being eaten by the proportion of four sheep to the acre; but suppose the number to be a hundred, as fifty of the late sheep hoggs, and the same quantity of shearing woe, there only remain then a hundred sheep for one hundred acres of grass-land, and of course there must be the means of keeping a number of bees in addition, or of having some portion of the land under meadow.

And in the common custom of sowing the drape-ewe by removing the lambs from them early in June, or the succeeding month, it is supposed the ewes may have sufficient time to become fat before the falling in of the winter, and be sold; and the sixteen acres of faimfinder-edinfs being suppoed to increase a profit on the sheep greater than that usually obtained. Further, that the lambs, by being put to the faimfinder, would be preferred found, while the ewes were in a fattening state.

Farm consisting of Open Tillage-land.

Extent several Hundred Acres.—It is situated in the northerly riding of Yorkshire, and managed on the old plan adopted in many parts of that district as the most beneficial.

The course of husbandry pursued is one fallow and two crops, in this way.

1st year, fallow, manured,
2d year, barley,
3d year, beans,
4th year, fallow,
5th year, wheat,
6th year, oats.

Profit of one acre of land for six years - - 17 6 9

On these data it is concluded that under the old plan of management, the farmer obtains only 1l. 9s. 3d. profit per acre from his land in six years, or 4s. 10d. per acre per annum. And the expense of labour is said to be flated higher than it really is, or he could not support his family and pay his rent: while under the improved husbandry, in the fame length of time, the profit is 17l. 6s. 9d. which is 2l. 17s. 9½d. per acre per annum, or more than 100 per cent. in its favour.

It is flated, that in this farm there is an open pasture, that is let at 2l. 6d. the acre, and the tenants consider it of no use to them: but under proper management, it is fupposed, that 5l. per acre of profit might be annually derived from it. Of course, the tenant may well be flurprised at being charged a new rent of 1l. 8s. the acre, though he now pays only 15s. and is fupposed highly rented according to his plan of management.

It is estimated, that the loss sustained at this rate on two thousand acres, is 29,625l. in fix years. If that number of acres were let at 1l. 8s. the acre yearly, there would be an advance of 13½ the acre, which would raise the sum of 7500l. more for the tenants to pay in fix years. And that sum taken from 29,625l. would still leave them a profit of 21,825l.

Though these estimates may appear extraordinary to those not familiar with the bufliness, they are founded in truth; and by pursuing proper courses, such profits as have been flated may be afforded to the landlord, as well as the tenant, independent of the benefit of green food during the summer. By a superiority of management in this way, the farmers in East Lothian are enabled to pay three or four pounds the acre. And if a perfon who lives by garden culture were to dig his ground one year in three, and that year raise no crop, he would be fupposed a madman. Yet the two crops and a fallow are work, as the land in this way is robbed of one-third of its manure. This may, indeed, be fupposed to open the eyes of the landlord, but it is also much to the benefit of the tenant.

These facts and statements fully display the vast benefits and improvements that are capable of being derived from the adoption of improved modes of husbandry in all cases where they can be admitted; though such detailed statements must necessarily have regard, in some degree, to the peculiar situations and other circumstances of the farms and lands.

A Farm conducted under different Modes of Husbandry.

In the view of displaying more fully the benefits of different modes of managing land, comparative statements of the profits resulting from a farm of four hundred acres employed under different modes of husbandry, in different circumstances, are given:

1st. In the grazing system.
2d. — the dairy practice.
3d. — the hay-felling system.
4th. — the tillage plan, near a large town.
5th. — the tillage plan more diffantly situated.
6th. — the tillage plan with improved course of crops.

Having noticed, that it is not rent that causes the poverty or riches of the farmer, but the difference in his mode of managing it, or the method of husbandry pursued, as a good plan of management improves land, especially under tillage in the most expeditious way of any; some estimates are given which clearly point out the great superiority of the tillage plan over any other that is had recourse to on the same ground in the way of a farm. In this case the rent is 50s. the acre, and the land sufficiently rich for affording profitable crops under judicious management.
1. Under the grazing System of Husbandry.

The extent of grazing land in this case is flat to be 500 acres, seventy in meadow, and thirty in tillage. The five stock on 200 acres, 150 oxen, bought in at 25s. each, and sold off at 30l. each; and on the remaining 100 acres, 75 cows at 17l. each, 4 milch cows; 300 ewes bought in at 45s. each, and sold off at 70s. to breed lambs for market; and 3 tups, at 5l. each. The lambs produced 400. fold at 35s. each; the wool of the ewes 5lb. each fleece, and sold at 40s. the tod. Eight horses and fix pigs.

These are thus flated:

II. Under the Dairy Practice.

In this case the farm is supposed to be principally in the rate of grasses, and employed in dairying; in which there are 220 acres in pasture, 150 in meadow, and 50 in tillage. The cow flock allowing 1½ acres to each, will be 140; with a bull or two, and a fix horses. The profit on cows, in calves, butter, and milk for the use of the hogs, 13l. each. The sheep flock, one ewe to the acre, on the pasture land, is 200 ewes bought in to breed lambs; the ewes and lambs to be made fat, and sold off, fresh flock being purchased annually; the produce in lambs will be 250, selling at 35s. each; and the ewes will cost 45s. each, which, when fat, will sell for 70s. each; their wool, at 5s. each, each flock, will make 35 tods of 20lbs., selling at 40s. the tod. The cows, if bought in at three years old, will cost 17l. each, and after having three calves, fell for 20l. each: consequently in this way, there will be about thirty-five cows to be changed annually. One horse will also be to be sold yearly, and one bought in. The tillage part, the same as in the grazing farm; 10 acres of wheat, 10 acres of beans, and 10 acres in summer fallow. The whole of the statement is thus made out.

IV. Under Tillage near a large Town.

The farm in this instance consists of 264 acres of land in tillage, thirty-six in meadow, and the remainder in grazing ground. The stock is supposed to be 12 horses for market work, and six for the purposes of tillage. The 100 acres of grazing land being flocked with oxen, at the rate of three to four acres; also six milch cows; and 100 ewes, one to the acre, to produce lambs; the produce about 125 lambs; consequently fresh flock will be yearly wanted. The oxen should be bought in, in the spring season at about 25l. each piece, being sold off at about 30l. The lambs, when fattened, will fetch about 35s. each. The ewes are purchased in about 45s. each; and disposed of at about 75s. each, being fattened on rape or turnips, sown on the land from which the garden peas had been taken. And the hay from the thirty-six acres of meadow land can, it is supposed, from the situation of the farm, be sent to market with more profit than by consuming it; there being two loads to the acre; the eddi being eaten off by oxen and sheep flock.

The expenses of making the hay are noticed to be estimated at 10s. the acre only, as the quantity being only 36 acres, it may be done wholly by the farmer's family; but where the business is hired, 20s. are as little as can be charged.

That part of the farm which is under tillage may be managed in such a mode of cropping, as to produce 14 crops in the course of 11 years, somewhat in this way:

### V. Under the tillage more distinctly situated.

This is similar in all respects to the above, except in situation, which renders it necessary to confine the hay and straw upon the farm; consequently the statements demonstrate the variations in value of different situations. It is supposed, as above, that 264 acres of the land are in tillage; 56 in meadow, and the remaining 100 in pasture. The last portion, stocked as before with 70 oxen; ewes, one to the acre, 100; there are supposed to afford 125 lambs, which are to be sold to the market, and the ewes fattened on the rape after the peas. The profit on these articles is explained in
HUSBANDRY.

in account No. 2: the oxen 5s. each profit; the lambs 3s. each; the ewes bought in at 4s. and sold off at 7s. being brought to the market in winter, when mutton is dear. Ten horses only, as few as will answer, there being only the corn to take to market; but more oxen should be kept. Such as are bought in, in the summer, should be fed on straw in the winter; four or six being employed in carting dung, harvest-work, &c. More pig-fodder may likewise be kept; fifty being put in the yards. And as the clover hay is here to be eaten, the oxen should have fame in the spring in the yard, to forward them for fattening off in the pastures. Consequently there is no profit in the hay, only from the oxen. Six of the horses to be annually fold, and others brought in. The oxen should be bought in, as there may be room in the summer, 88 being provided annually, and fattened, so as to have fresh flock every season: 18 being fed out in winter, and 70 in the summer fearen.

Expenses of Stock, &c. (Account 1.)

By a trifling mistake in most of the above statements, the house-keeping and expenses have been put into one of the separate accounts, instead of the general account, at the end of each farm; and in the same manner, the rent charged in account four, should have been brought into account 5; but these are of little consequence, as the sums of total profit must have been the same.

The tilage-land in this case is under the same course as in the preceding farm.

* Though all the straw and clover be consumed by the horses, cattle, &c. on the farm; yet, as the ploughing, harrowing, manuring, &c. of the crops are charged at the full price, it is necessary that in this account a fair rate should be allowed for the whole of the produce.

Crop
HUSBANDRY.

And it is suggested, that by the improved manner of cropping employed there will never be more than twenty-four acres to manure at any one time, except at the wheat sowing season, and then even the quantity may be divided by that part of the land which has grown the potatoes being sown first, at the time they are taken up. By pulling up all the tops, and depositing them in the farm yards as litter, they, as well as the earth that is carried with them, will be returned to the land. The small potatoes should be used for the pigs. And by sowing the wheat immediately on the land cleared from the stems of the potatoes previous to their being ploughed up, an advantage is said to be derived. But from the danger of frost, no more of the tops should be removed at a time than can be ploughed up during the day.

In following this method, the next sowing of wheat will, it is supposed, be on the land that has grown rape for seed. It may likewise be sown first, where the potatoes are not ready to be taken up. And the third time of sowing wheat will be on the clover lay; in which case there is plenty of time, as it may be done in winter, with nearly equal success, as from September to January. In this, however, is not the case with spring crops, as all those of the grain kind should be got in as speedily as possible. But bean and pea crops may always be put in the full a fortnight or three weeks previously to those of the corn kind; and it is noticed, that where the land is all prepared, and the teams taken off for the purpose, there will be nine pairs of horses, which will be capable of harrowing in the whole of these crops in three days. And the twenty-four acres of barley, and the twenty-four acres of wheat may be harrowed in the same space of time. This is considered as one of the great benefits of large teams, as such a great number being employed in carrying the produce, they are capable of being made use of for about twenty days in seed-time and harvest, and, of course, to earn nearly what they cost in keep in the whole of the year.

Other benefits are supposed to result from this scheme of cropping; the harvest labour is more divided; the flax and pea crops are ready in July, afterwards the oaks, then the wheat, and lastly the beans. This, while it increases convenience, lessens expense. The rape may be thresher in the field, and folded early in August, furnishing money for the expenses of the remaining harvest. Besides, there is hardly a month of the year, in which considerable returns of money are not coming in from one or other of the different operations. The flax may be sold on the ground to pull in July by the purchaser, which usually affords from seven to nine guineas the acre, which, though apparently a small sum in comparison with some other sorts of crops, is staked as paying well for the time it occupies the ground; which is only about three months, being sown in April and pulled in July. By all these means the expenses are diminished, and of course larger profits afforded. In short, these detailed accounts furnish the cultivator with the means of judging of the most advantageous modes of employing his land in the view of profit. They seem to prove three of the methods of farming to be very indifferent concerns; tillage husbandry having vantage the advantage over them; and it is supposed that many further improvements are still to be made in it; for which various hints are thrown out, and different calculations introduced.

It must constantly be kept in mind that, in all the different schemes of husbandry, the profits and benefits are to proceed, not only from the superiority of the management that may be employed, but the nature of the situation in regard to the facility and cheapness of flocking the land, and the ease of cultivating it; as in some places the expenses of
of the farmer will not be more than from five to seven or eight pounds the acre; while, in others, it may be from ten to twelve or thirteen pounds the acre, as is the case in several parts of England; and consequently the expenses in the same proportions, though the variations in the markets for the different produce may be but trifling.

It would be easy to introduce other calculations on arable, and farms of other kinds, where great improvements are to be effected by plowing, chalking, marling, liming, &c.; but as they may be regulated by the local nature of the different situations, they could be of but little utility in guiding the practice of the farmer.

It does not admit of a doubt, that husbandry has been greatly improved in most of its different branches within these few late years in this country. Far better modes of cropping land, and of combining the feeding of cattle with arable management, have been introduced and adopted. More appropriate, cheap, and convenient tools for various purposes of tillage and other practices of farming have been invented; and most of the processes and operations of the art rendered more simple and easily performed. Yet still, if those laws and regulations which repel the efforts of the cultivator were modified or removed; leaves more generally and liberally granted, for moderate periods of time; and the dissemination of useful information on rural business carefully attended to, the state of cultivation would soon be advanced to a much higher degree of perfection than it has yet attained.

**Husbandry. Broach-cult.** See Broad-cast.

**Husbandry. Drill.** That form in which the seed is deposited in small furrows, drills, or openings, in rows, at different distances, according to the nature and circumstances of the soils and the crops by suitable machinery, and in which the after-culture is performed by the use of the horse-hoe, or other tools of a similar kind. See Hor. Hoeing, and Machine Drill.

For the introduction and extension of this method of husbandry in this country, we are principally indebted to Mr. Tull and his followers, who, in promoting it, seem to have considered it as altogether new; but this would appear from the account which has lately been published in the first volume of Communications to the Board of Agriculture, by Mr. Halford, not to be the case, as it has been found to be the general practice in the Incaudah district in the East Indies, in the cultivation of all sorts of grain, except those of the horse kind, as well as in the growth of hemp, tobacco, cotton, and even the inferior oil plant. And it is ascertained on good authority, that, in Arabia, China, and Japan, where the modes of husbandry have not undergone any material change for thousands of years, they do not only drill, but dibble corn of every description. It is of course probable, that the drill method of husbandry is of considerable antiquity, and that it was brought to Europe from some of the eastern nations.

But though this method of husbandry obviously possesses many advantages over that which is generally employed by farmers, it is far from being in general use in this kingdom; the reason of which is explainable to proceed from the difficulty of making common labourers acquainted with the nature of the practice; the incorrectness of the machinery that is made use of in delivering the seed, and the expense which is necessary for the first undertaking of the business. Other causes have likewise a tendency to impede its advancement, such as the introduction of it on land that is not in a proper state of preparation for its reception, either in regard to quality or the nature of the tillage, and the neglecting in some measure the after-culture of the crops, upon which so much of its success depends. The attempting too great savings in the quantity of seed employed, by sowing too thinly in the drills, as well as at too great distances between the rows, has also in many instances operated much against it.

The foils that are most proper for this fort of husbandry, are all those of the more light and friable kinds, which are not so strong, heavy, or wet, as to prevent the working of the machinery which is necessary in executing the bushcants. It can scarcely ever be had recourse to with much advantage; except for particular sorts of crops, on the light, heavy, wet, clayey foils, as the work must constantly be liable to be performed in an incomplete manner, nor even in such as are of a very flimsy quality, as those obstructions will constantly be apt to derange the operations of the machine, and thereby render the sowing irregular and improper.

But whatever the nature or quality of the soil may be on which this fort of husbandry is attempted, it should constantly be brought into a fine state of tilth by repeated ploughing, and other modes of pulverization, before the crops are put into the ground.

In doing which it will also be necessary to suit them, and the proportion of seed to the nature and quality of the land, and the distance of the rows to their growths; as well as to preserve a continued attention to their after-culture while on the ground.

In the practice of this method of culture different distances in the rows and intervals have been advised, as disadvantages must obviously proceed from their being either too narrow or too large; in the former little benefit being capable of being derived in the cultivation of the crops after they have been deposited in the soil; while in the latter there will be great loss sustained in the over quantity of land that is taken up. It is probable, that in regard to distances, as well as the modes of drilling, much must constantly depend on the state and quality of the land.

Upon dry light soils, whether of the loamy, gravelly, or chalky kinds, which can be constantly ploughed and preserved on the flat, as is the case in East Kent, narrow distances are supposed the most proper. But where ridgeing up is required, they should be somewhat wider. It was found by actual trials that drilling three rows eleven or twelve inches asunder, on three hout ridges, generally succeeded in a perfect manner. In this way, the three rows constitute a ridge about four and a half feet in breadth; the three rows as just mentioned occupying two feet, and the horse-hoe going on the side of each outside row, at the distance of three inches, leaves the ridge two and a half feet broad, and the intervals between them nearly two feet. But it has been suggested, that, in these cases, as the outside rows constantly afford the strongest and most healthy plants, two rows only, on two-hout ridges, would be equally productive, and leave the ground in a better state of tilth. However this may be, the very wide intervals of the more early drill practice are to be discarded as highly improper in all crops of the grain kind, not only in consequence of the great loss of ground that must necessarily be sustained by such wide intervals; but because the spaces between the rows, when much narrower, can, in the improved mode of horse-hoeing, be filled with equal correctness and facility.

In practising this method of husbandry, it has been hinted by an experienced cultivator, that, with regard to wheat and barley, the distance of the rows should greatly depend on the quality of the soil. In cases where it is poor, the spaces between the rows should not be more than about eight
eight inches; where of a medium quality about nine inches, and where rich, not more than ten inches. The quantity of feed being made to vary in the same way, from about nine pecks to eight and seven. And the depth of depositing it from two inches and a half to two inches.

In the extensive experience of the late Mr. Clope, nine inches was the distance that answer'd well for white corn crops. See Sowing of Grain.

But for various sorts of green crops, such as those of the potatoe, cabbage, rape, turnip, carrot, parsnip, bean, peas, and other similar kinds, much wider distances are requisite, as is sufficiently shown under the culture of these different descriptions of crops.

The great advantages of this method of husbandry, are those of its affording the means of distributing the feed with much greater correctness in regard to depth, as well as regularity in the rows, by which the growth of the crops is not only more uniform, but after-culture capable of being more effectually executed, and at the same time some saving of feed effected. And as the feed grain in this way is neither too closely crowded together, nor too thinly fatted in the drills, there is less danger of injury in the weaknesses of the produce from the former cause, or of loss from the too scanty number of stems in the latter, which is almost constantly the case in the common mode of management.

Defies, by the equality of the depth to which the feed is deposited in this way, the crops become ripe in a more equal and uniform manner. Further benefits are likewise derived in different ways, by the frequent flitting and breaking down of the mould about the roots and stems of the plants, while the crops are upon the ground. By such frequent turning the soil becomes newly and fully aerated, in consequence of which different nutritive matters are more abundantly formed and provided for the support of the crops; and the earth at the same time rendered more easily penetrable by the superficial roots of the grain, and its power of tillering increased by the mould being laid up to the joints of the stems, just above the surface of the land. There are also other ways in which benefit is derived in this mode of cultivation; as by the more effectual eradication of weeds that continually takes place, the harrowing of the crops is more readily and certainly accomplished, and at less trouble and expense; while the land is left in a more mellow and fine state for the production of future crops, as well as for the immediate putting in of succeeding ones. See Hoeing.

Husbandry, Implements of, the various sorts of tools that become necessary in the cultivation and management of land, as those of the tillage, dairy, and other kinds. See Implements of Husbandry.

Husbandry, Virgiliar, a term used by authors to express that sort of husbandry, the precepts of which are so beautifully delivered in Virgil's Georgics. The husbandry in England is Virgilius in general, as is seen by the method of paring and burning the surface, of mowing or cross-ploughing, and of the care in destroying weeds upon the same principle, and by much the same means. In those parts of England along the southern coast, where the Romans principally inhabited, not only the practice, but the expressions are in many respects the same with those of the ancient Romans, many of the terms used by the ploughmen being of Latin origin, and the same with those used by those people on the like occasions. And on a strict observation, more of Virgil's husbandry is at this time practised in England than in Italy itself. This change in the Italian husbandry is, however, much more to the credit of that people than the retaining the Virgilian scheme is to our's.

Tull, who has established a new method of husbandry, observes that it is upon the whole fo contradictory to this old plan, that it may be called the anti-Virgilian husbandry; and adds, that no practice can be worse than the Virgilian.

HUSBRECE, in our Old Writers, an offence now called burglary.

The word is Saxon, from hus, a house, and brice, a breaking. Blount, in voc.

HUSBRE, in Geography, a town of Sweden, in Dalecarlia; nine miles N. of Hedemora.

HUSCONS, in our Old Writers, a sort of boot or bootik made of coarse cloth, and worn over the stockings. We find them mentioned in the vat. 4 Edw. iv. cap. 7.

HUSSET, in Geography, a town of Hungary; 24 miles E. of Munkacz.

HUSABLE, HUSBALUM, in our Old Writers, denotes houfe-roots, or some tax or tribute laid upon houses.

HUSHING, in Mining, is applied, in Cornwall, to a mode of discharging flat and flat tin, or alluvial collections of tin ore, by turning a strong stream of water successively over different parts of the surface, to wash away all the vegetable soil and loose earth. (William's Mineral Kingdom, vol. i. p. 513, 2d edit.). Around Merthyr Tydvil, and other places in South Wales, much of the iron ores are obtained by this destructive process, equally depriving the sides of hills of their soil, and covering valuable meadows with this earth and frones: many hundred acres of valuable meadows below Merthyr town have, within a few years past, been covered several feet deep with earth and frones, over which every flood of the river spreads and moves and disturbs it, so that the whole width of the valley is without vegetation, and presents a scene of devastation, nowhere else to be witnessed, but on the sand and beach of the flat shores of the ocean: already a strong wall has been found necessary to confine the stream and this torrent of earth from overwhelming the lower part of the town, which is increasingly in danger of the fate of Oltia on the Tiber, if this destructive mode of disposing of the rubbish from the iron-lome mines is suffered much longer to exdil.

HUSK, among Botanists, the part which a flower grows out of. See Glume.

The husks or caps of the flowers of plants are not so much regarded with a view to their medicinal virtues as they deserve. Petiver, in the Philosophical Transactions, speaking of the virtues of the verticillate clasps of plants, among which are included the fage, rosemery, and the like, observes that it is an erroneous, though general opinion, that the flowers of these plants contain their principal virtues, for that the husks are the part in which it is lodged. For instance, in the rosemery, the fine scent of the Hungary-water is not in the flowers, but husks; and the flowers alone, when clean picked from them, yield very little odor. The cup, in this and other plants of the same clasp, is the only part in which their viscious and fulphureous qualities are lodged, and that something of this kind is deposited particularly there, may be perceived by the touch and smell; for they appear moist, and feel clammy; and this clammy matter, when received upon the fingers, is of a very strong and agreeable smell, much more so than the husk of the plant.

HUSK denotes a disease of young bullocks. See Cough.

HUSKS, Poffik, in Natural History. The husks, shivers, juli or catkins, and other light parts of hazel, alder, willow, &c. are found in great quantities deep in the alluvian earth, and peat, of wide and flat valleys. Parkinson's Org. Rem., vol. i. p. 94.
HUSO GERMANOIMUM, in Ichthyology, the name of a large fish of the Sturgeon or scipenfer kind, without tubercles, caught in the Danube, Borilinhes, and other large rivers, and pafting at times into the sea. It has a very long front, and under it either four or eight beards; it has one back-fin, which is placed near the tail, and two pair under the belly; its general shape somewhat resembles that of the pike, and its back is black and its belly yellow; it has thirteen dorsal and forty-three caudal scales, and has cartilages instead of bones. It is caught in October and November, and in some places till January; and great numbers of them are usually brought to market together in those months in the countries where they are caught. They always swim in schools. It grows to twenty-four feet long, and weighs one, two, three, or even four hundred pounds. The drug called eingafs, and the food called cavare, are prepared from this fish.

Huss, John, in Biography. See Husites.

Hussars, Hussards, or Hussites, an order or species of fowder in Poland and Hungary, commonly opposed to the Ottoman cavalry.

The hussars are horsemen, whose uniform is a large furred cap, adorned with a cock's feather; those of the officers with an eagle's or hero's; a very short waistcoat with breeches and stockings in one piece; short light boots; and a doublet, having five rows of buttons, which hangs loosely on the left shoulder. Their arms are, a long crooked fabric, light carbines, and pistols. Before they begin a attack, they lay themselves flat on the necks of their horses; but being come within pistol shot of the enemy, they raise themselves with such quickness, and fall on with such altemuts, that it is very difficult for the troops oppofe to preferve their order. In a retreat no other cavalry can pretend to follow them; as they leap over ditches, and swim through rivers with a surprifing facility. Most of the princes on the continent have troops under this name.

Husseianabad, in Geography, a town of Aftacie Turkey, in the government of Sivas; 42 miles S.W. of Amascul.

Husseingunye, a town of Hindoostan, in Rohilcund, on the Ganges; 26 miles W.S.W. of Budayoon.

Husses, a town of Arabia, in Yemen; seven miles E. of Sana.

Hussey, Giles, in Biography, a painter, born of a good family, in Dorsetshire. He was the pupil of Richardson in England, and afterwards of Damini and Erecole Lelli, in Italy, where, during a day of some years at Rome and Bologna, he rufed expectations which were effenfially diapointed on his return. Diftaining portraiture, dif commendence in hiftorv, Husfe was reduc to the soliditary patronage of the then duke of Northumberland, who offered to receive him into his family, and give him a handsome pension, with the attendance of a servant, upon the condition that he should employ his talents chiefly, though not exclusively, for the duke. This offer he refuited, becaufe the duke did not comply with his requifite of keeping a ped in the home for him. Hussey, a bigot in religion, was attached to the creed of Rome; but had he not been fo, commifions and patronage, almost confined to drawing copies, even from the antique, was certainly sufficiently provoking for a man of an original turn of mind to be refuited. He afterwards became exceedingly diftrefied for the means of living; but upon making his wants known to his brother, who had succeeded to the family estate, he was allowed his own kind manner; and, after his generous brother's deceafe, enjoyed himfelf the edate for some years, after which he difported of it, and retired to Bexfon, in Devonshire, where he died, in 1788, at the age of 71.

Hussey was a complete infance of the danger of philosophizing too much upon art, which requires more practice and good fense than over-refined yflemis of thinking. He spent the left part of his life in rediving, ufefully, the proportions of the human form, and all its various actions, to the musical scale of concords, and produced fanciful analogies which no painter, whose mind is capable of grafting the true beauties of art, will flay, or ought to flay, to confider. Thus he left the time which should have been devoted to the practice of art, and when the hand and the imagination were required, both were found deficient. But he was an ingenious and highly respectable character.

Hussingabad, in Geography, a town of Hindoostan, in the cirear of Hindia, on the S. bank of the Nerbuddah river; 120 miles N.E. of Bariipour. N. lat. 22° 42° 50'.

Hussites, in Ecclesiatical History, a party of reformers, the followers of John Hus.

John Hus, from whom the Hussites take their name, was born in a little village, called "Huffinez," in Bohemia, about the year 1376, and lived at Prague, in the university of which he was educated, in the highest reputation, both on account of the faculty of his manners, and the purity of his doctrine. In the year 1396 he took the degree of M. A., and soon after that of B. D. In 1400 his abilities and piety had so far recommenced him, that he was chosen confessor to the queen, and eight years after he was elected rector of the university. He was distinguished by his uncommon erudition and eloquence, and performed at the fame time the functions of professor of divinity in the university, and of ordinary paffor in the church of that city. During the confe of these honours he obtained a benefice ample endowed by John Mulheym, a perfon of large fortune at Prague. By the marriage of Ann, sister of the king of Bohemia, with Richard II. of England, in 1381, a communication and intercourse were opened between England and Bohemia; and a young Bohemian nobleman, who had finifhed his studies in the university of Prague, spent fome time at Oxford; and on his return put into the hands of Hus the writings of Wickliff. He adopted the sentiments of Wickliff, and the Waldenfes; and in the year 1407 began openly to oppofe and preach againat divers errors in doctrine, as well as corruptions in point of discipline, then reigning in the church. Hus's like wife endeavoured to the utmost of his power to withdraw the university of Prague from the jurifdiction of Gregory XI., whom the kingdom of Bohemia had ladiito acknowledged as the true and lawful head of the church. This occasioned a violent quarrel between the inlenfed archbishop of Prague, who was an ileritate man, to fuch a degree that he was called "Alphabetarius," or the A B C doctor, and who, without fufficient authority from the pope, had committed the works of Wickliff to the flames; and the zealous reformer, which the latter inflamed and augmented, from day to day, by his pathetic exclamations againat the court of Rome, and the corruptions that prevailed among the facerdotal order. The archbishop, by his own authority, prohibited Hufs from preaching in his chapel of Bethlem, to which he had been appointed by Mulheym; upon which Hufs, as a member of the university, which held immediately of the Roman fee, appealed to the pope.

There were other circumstances that contributed to inflame the reiment of the clergy against him. He adopted the philofofical opinions of the Realists, and vehemently oppofed and even perifurated the Nominalists, whose number and influence were considerable in the university of Prague. He also multiplied the number of his enemies in the year 1428, by purchafing, through her great credit, a sentence in favour of the Bohemians, who disputed with the Germans concerning the number:
number of suffrages which their respective nations were entitled to; all matters that were carried by election in this university. In consequence of a decree, obtained in favour of the former, which restored them to their constitutional right of three suffrages, usurped by the latter, the Germans withdrew from Prague, and in the year 1409, founded a new academy at Leipzick. This event no sooner happened than Hufus began to inveigh with greater freedom than he had before done against the vices and corruptions of the clergy, and to recommend, in a public manner, the writings and opinions of Wickliff, as far as they related to the papal hierarchy, the despotism of the court of Rome, and the corruption of the clergy. Hence an accusation was brought against him, in the year 1410, before the tribunal of John XXII., by whom he was solemnly expelled from the communion of the church. Notwithstanding this sentence of excommunication, he proceeded to expel the Romish church with a fortitude and zeal that were almost universally applauded.

Some tumults having taken place among the followers of Hufus, in which he had no concern, and which, indeed, he lamented, and endeavoured to suppress, Wenceslaus, king of Bohemia, bannish'd him from Prague, upon which he retired to his native place, and lived there unmolest'd. During his retreat at Hulifez he composed his celebrated treatise "Upon the Church;" and here he also dated a paper entitled "The Six Errors," which he fixed on the gates of the chapel at Bethem. It was level'd against indulgences, the abuse of excommunication, believing in the pope, the unlimited obedience required by the fee of Rome, simony, and making the body of Christ in the mafs.

This eminent man, whose piety was equally sincere and fervent, though his zeal was perhaps too violent, and his prudence not always circumspect, was summoned to appear before the general council of Conilance, convened in the year 1414; whither princes and prelates, clergy and laity, regulars and seculars, flocked together from all parts of Europe. Secured, as he apprehended, from the rage of his enemies by the safe conduct granted him by the emperor Sigismund, for his journey to Conilance, his residence in that place, and his return to his own country; John Hufus obeyed the order of the council, and appeared before it, to demonstrate his innocence, and to prove that the charge of his having defeated the church of Rome was entirely groundless. However, his enemies so far prevailed, that, by the most scandalous breach of public faith, he was call'd into prison, declared a heretic because he refused to plead guilty against the dictates of his conscience, in obedience to the council, and burnt alive July 6th, 1415; a punishment which he endured with unparalleled magnanimity and resigna-

We shall here subjoin some farther interesting particulars relating to the close of this eminent reformer's life. Whilst his fate was in suspense, his friends in Bohemia were sufficiently active; and at length a petition was sent through the kingdom, and subscribed by almost the whole body of the Bohemian nobility and gentry. It was dated in May, 1415, and was addressed to the council of Conilance. The first petition, complaining of the treatment which he had received, soliciting that a speedy end might be put to his sufferings by allowing him an audience, having been diredgarded, a second and a third were presented, urging his release, and offering any security for his appearance. The last petition to the council was accompanied by another to the emperor, confirming the demand to his honour follow'd by engaged for the security of Hufus, and imploring his protection and inter-

The following opinions, among many others, which gave offence, were esteemed most criminal: "That there was no absolute necessity for a visible head of the church; that the church was better governed in apostolic times without one; that the title of holiness was improperly given to man; that a wicked pope could not possibly be the vicar of Christ, that he denied the very authority on which he pretended to act; that liberty of conscience was every one's natural right; that ecclesiastical censures, especially such as touched the life of man, had no foundation in scripture; that ecclesiastical obedience should have its limits; that no excommu-

nination should deter the erring from his duty; that preaching was as much required from the minister of religion, as alms-giving from the man of ability; and that neither of them
them could hide his talent in the earth without incurring the divine displeasure." Paletz and the cardinal of Cambray were the chief managers of this examination.

Besides these opinions, most of which were proved and acknowledged, he threw out many things in the course of his examination which were eagerly laid hold on; particularly against the scandalous lives of the clergy of every denomination; the open simony practised among them, their luxury, looseness, and ignorance.

Hus having now been examined on all those articles which the nicety feretiny into his books, and the most revolting remembrance of his words could furnish, the cardinal of Cambray thus assailed him: "Your guilt hath now been laid before this august assembly with its full force of evidence; I am obliged, therefore, to take upon me the disagreeable task of informing you, that only this alternative is offered to you: either to abjure these damnable errors, and submit yourself to the council, in which case these reverend fathers will deal as gently with you as possible, or to abide the fever and con¬sequence of an obdurate adherence to them."

To this Hus answered, "that he had nothing to say, but what he had often said before; that he came there not to defend any opinion obstinately; but with an earnest desire to see his errors and to amend them; that many opinions had been laid to his charge, some of which he had never maintained, and others, which he had maintained, were not yet confuted; that as in the first case, he thought it absurd to abjure opinions which were never his; so in the second, he was determined to subscribe nothing against his conscience."

The emperor told him, he saw no difficulty in this rescuing errors which he had never held. "For myself," he said, "I am, at this moment, ready to renounce every heresy that hath ever existed in the Christian church; does it therefore follow that I have been a heretic?"

Hus respectfully made a distinction between abjuring errors in general, and abjuring errors which had been falsely imputed; and prayed the council to hear him upon those points which to them appeared erroneous; were it only to convince them that he had something to say for the opinions he maintained. To this request, however, the council paid no attention.

Here Paletz and de Caffis took an opportunity to exculpate themselves of any appearance of malice in this disagreeable profession. They both entered upon the task with great unwillingness, and had done nothing but what their duty required. To this the cardinal of Cambray added, that he could sufficiently exculpate them on that head. They had behaved, he said, with great humanity; and to his knowledge might have acted a much feater part.

The emperor observing, that every thing, which the cause would bear, had now been offered, arose from his seat, and thus addressed himself to the council:

"You have now heard, reverend fathers, an ample detail of heresies, not only proved, but confuted; each of which unquestionably, in my judgment, deserves death. If, therefore, the heretic continue obstinate in the maintenance of his opinions, he must certainly die. And if he should even abjure them, I should by no means think it proper to send him again into Bohemia; where new opportunities would give him new spirits, and raise a second commotion worse than the first. As to the fate, however, of this unhappy man, be that as it may hereafter be determined; at present, let me only add, that an authentic copy of the condemned articles should be sent into Bohemia, as a ground-work for the clergy there to proceed on; that hereby may at length be rooted up, and peace restored to that distracted country."

The emperor having finished his speech, it was agreed in the council to allow Hus a month longer to give in his final answer. With the utmost difficulty he had supported himself through this severe trial. Besides the malice of his enemies, he had upon him the paroxysm of a very violent disorder. On this last day he was so fearfully able to walk, when he was led from the council. His consolation in these circumstances was a cold and hungry dungeon, into which he was inhumanly thrust.

His friend, the baron, attended him even hither, and with every instance of endearing tenderness, endeavoured to support him. The suffering martyr wrung his hand; and looking round the horrid scene, earnestly cried out, "Good God! this is friendship indeed!" His keepers soon after put him in irons; and none but such as were licenced by the council were allowed to see him.

The generous nature of Sigismund, though he was not unversed in the artifice of the cabinet, abhorred a practised fraud. The affair of Hus, amid all the cajufcdy of the counsellors, gave him keen distress; and he wished for nothing more ardently than to rid his hands of that honour. On the other side, his vanity and his interest engaged him to appear the defender of the Catholic cause in Germany. If he suffered Hus to be put to death one part of the world would question his honour; if he interfered with a high hand in preferring him, the other part would question his religion. The perplexity was great; from which he thought nothing could relieve him but the recantation of Hus.

To obtain this he tried every means in his power. He had already endeavoured to intimidate him with high language which he had used, both in the council and in other places. But this was ineffectual. He had now recourse to soothing arts. The form of a recantation was offered; in which Hus was required only to renounce those heresies which had been fairly proved. But he continued still inflexible. Several deputations were afterwards sent to him in prison; and bishops, cardinals, and princes in vain tried their eloquence to persuade him.

Sigismund, seeing the conclusion to which this fatal affair was approaching, might probably have interceded himself thus far, as thinking he had been too condescending to the council. The flame also, which he saw kindling in Bohemia, where he had high expectations, and was willing to preserve an interest, might alarm him greatly. He had gone too far, however, to recede, and knew not how to take Hus out of the hands of the council, into which he had given him with so much zeal and devotion.

In the mean time Hus remained master of his fate, and shewed a constancy which scarce any age hath excelled. He ammied himself, while it was permitted, with writing letters to his friends, which were privately conveyed by the Bohemian lords who visited him in prison. Many of these letters are still extant. The following, which is the substance of one of them, may be a tref of that composed piety and rational frame of mind which supported him in all his sufferings.

"My dear friends, let me take this last opportunity of exhorting you to truit in nothing here, but to give yourselves up entirely to the service of God. Well am I authorized to warn you not to truit in princes, nor in any child of man, for there is no help in them. God only remaineth steadfast. What he promiseth, he will undoubtedly perform. For myself, on his gracious promise I reit. Having endeavoured to be his faithful servant, I fear not being deferrated by him. Where I am, says the gracious Promiseth, there shall my servant be. May the God of heaven preserve you!—This is probably
Hussites.

probably the last letter I shall be enabled to write. I have reason to believe I shall be called upon to-morrow to answer with my life. Sigismund hath in all things acted deceitfully. I pray God for him! Have I ever heard in what severe language he hath spoken of me?"

The month, which had been allowed by the council, being now expired, a deputation of four bishops came to receive his last answer, which was given in the same language as before.

The sixth of July was appointed for his condemnation, the scene of which was opened with extraordinary pomp. In the morning of that day, the bishops and temporal lords of the council, each in his robes, assembled in the great church at Constance. The emperor prorided in a chair of state. When all were seated, Hus was brought in by a guard. In the middle of the church a scaffold had been erected; near which a table was placed, covered with the vestments of a Romish priest.

After a sermon, in which the preacher earnestly exhorted his hearers to cut off the man of sin, the proceedings began.

The articles alleged against him were read aloud; as well to the people, which he had, as to the people which he had not allowed. This treatment Hus opposed greatly; and would gladly, for his character's sake, have made a distinction; but finding all endeavours of this kind ineffectual, and being indeed plainly told by the cardinal of Cambrai, that no farther opportunity of answering for himself should be allowed, he declined; and falling on his knees, in a pathetic ejaculation, committed his cause to Christ.

The articles against him, as form required, having been recited, the sentence of his condemnation was read. The instrument is tedious; in substance it runs, "That John Hus, being a disciple of Wickliff, of damnable memory, whose life he had defended, and whose doctrines he had maintained, is adjudged by the council of Constance (his tenets having been fir'd condemned) to be an obfolute heretic; and as such, to be degraded from the office of a priest; and cut off from the holy church."

His sentence having being thus pronounced, he was ordered to put on the priest's vestments, and ascend the scaffold, according to form, where he might speak to the people; and, it was hoped, might fill the grace to retract his errors. But Hus contented himself with saying once more, that he knew of no errors which he had to retract; that none had been proved upon him; and that he would not injure the doctrine he had taught, nor the confessions of those who had heard him, by ascribing to himself errors, of which he had never been convinced.

When he came down from the scaffold, he was received by seven bishops, who were commissioned to degrade him. The ceremonies of this business exhibited a very uncivilian scene. The bishops, forming a circle round him, each adding a curse took of a part of his attire. When they had thus stripped him of his facerdotal vestments, they proceeded to erate his tonsure, which they did by clipping it into the form of a croq. Some writers say, that in doing this, they even tore and mangled his head, but such stories are unquestionably the exaggeration of Protestant zeal. Their last act was to adorn him with a large paper cap; on which various and horrid forms of devils were painted. This cap one of the bishops put upon his head, with this uncivilian speech, "Hereby we commit thy soul to the devil." Hus smiling, obeyed, "It was less painful than a crown of thorns."

The ceremony of his degradation being thus over, the bishops presented him to the emperor. They had now done, they told him, all the church allowed. What remained was of civil authority. Sigismund ordered the duke of Bavaria to receive him, who immediately gave him into the hands of an officer. This person had orders to see him burned, with every thing he had about him.

At the gate of the church a guard of 800 men waited to conduct him to the place of execution. He was carried first to the gate of the episcopal palace, where a pile of wood being kindled, his books were burned before his face. Hus smiled at the indignity.

When he came to the stake, he was allowed some time for devotion; which he performed in so animated a manner, that many of the spectators, who came there sufficiently prejudiced against him, cried out, "What this man hath said within doors we know not, but surely he prayeth like a Christian."

As he was preparing for the stake, he was asked whether he chose a confessor? He answered in the affirmative; and a priest was called. The design was to draw from him a retracement, without which, the priest said, he durst not confound him. "If that be your resolution, said Hus, I must die without confession: I trust in God, I have no mortal sin to answer for."

He was then tied to the stake with wet cords, and fastened by a chain round his body. As the executioners were beginning to pile the faggots around him, a voice from the crowd was heard, "Turn him from the east; turn him from the east." It seemed like a voice from heaven. They who conducted the execution, struck at once with the impropriety, or rather profaneness of what they had done, gave immediate orders to have him turned due west.

Before six was brought, the duke of Bavaria rode up, and exhorted him once more to retract his errors. But he still continued firm, "I have no errors," said he, "to retract; I endeavoured to preach Christ with apostolic plainness; and I am now prepared to feel my doctrine with my blood."

The faggots being lighted, he recommended himself into the hands of God, and began a hymn, which he continued singing, till the wind drove the flame and smoke into his face. For some time he was invisible. When the rage of the fire abated, his body, half consumed, appeared hanging over the chain; which, together with the soil, were thrown down, and a new pile heaped over them. The malice of his enemies purified his very remains. His ashes were gathered up and scattered in the Rhine, that the very earth might not feel the load of such enormous guilt.

From this view of the life and sufferings of Hus, it is hard to say what were the real grounds of the animosity he had raised. His creed unquestionably was far from being exactly orthodox; yet it is plain how very ill able his adversaries were to gather from it offensive matter enough for an accusation. He believed transubstantiation; he allowed the adoration of saints; he professed confession; he spoke contemptuously of tradition, and reveredly of the seven sacraments; and whatever latitude he might give himself on any of these articles, it was not more than had been often taken, inoffensively taken, by Gerbon, Zabarella, and other spirited divines of the Romish church.

Besides, the great pains the council took to avoid a public question, and the great confidence with which Hus desired one, are presumptions very strong in his favour.

It is the opinion of Lenfant, that the great cause of his condemnation was his introducing Wickliff's doctrine into Bohemia; and chiefly perhaps that offensive part of it which struck at the temporalities of the clergy. And, indeed, this is extremely probable from the whole conduct of the council; for though it is apparent, that he never adopted the entire system of that reformer; yet his principles, if certain, would have led him much farther than they had hitherto
done; and the fathers of the council being aware of this, seem to have determined, though at the expense of justice, to crush an evil in its origin, which appeared teeming with so much mischief.

Besides this, there seems to have been another cause for that unabated prejudice which ran so high against him. The warmth with which he treated the corruptions of the clergy, and the refractions of the church of Rome, is a crime never to be forgiven by the ecclesiastics of these times; and added the keenest edge to their resentment. But as this was an unpopular cause to appear in, it is plain they wanted to have it believed their judgment stride upon another account. This seems to have been the foundation of a speech, attributed by Villaros to cardinal Perron; "My learned friends," (he would say) "you cannot employ your time worse than in giving the world any account of the affairs of Hus."

His life, however, was the severest satire upon the clergy. It was a mirror which reflected their distorted features. In him they saw the true ecclesiastic and the real Christian, characters so different from their own. Gentle and condescending to the opinions of others, this amiable pattern of virtue was strict only in his own principles. The opinions indeed of men were left his concern than their practice. His great cause was with vice; and he treated the mischiefs of religion with freedom, only as he thought their example encouraged, rather than checked, that licence which prevailed. The great lines in his character were piety and fortitude. He was calm, rational, and manly; his piety nothing human could daunt. The former was free from enthusiasm; the latter from weakness. He was in every respect an apolitical man. "From his infancy," (says the university of Prague in a voluntary testimonial,) he was of such excellent morals, that during his stay here, we may venture to challenge any one to produce a single fault against him.

As to his parts and acquisitions, he seems to have been above mediocrity; and yet not in the highest form in respect of either. A vein of good sense runs through all his writings, but their distinguishing characteristics are simplicity and piety.

To prefer the memory of this excellent man, the sixth of July was, for many years, held sacred among the Bohemians. A service, adapted to the day, was appointed to be read in all churches; and instead of a sermon, an oration was spoken in commemoration of their martyr, in which the noble strain he made against ecclesiastical tyranny was commemorated, and his example propounded as a pattern to all Christians.

In some places large fires were lighted in the evening upon the mountains, to preserve the memory of his sufferings; round which the country-people would assemble, and sing hymns in his praise.

A very remarkable medal was struck in honour of him, on which was represented his effigies, with this inscription, CENTUM REVOLUTIS ANNIS DEO RESPONDIDERIT ET MIHI. These words are said to have been spoken by him to his adversaries a little before his execution; and were afterwards applied by the zealous of his sect as prophecies of Luther, who lived about a hundred years after him. The flory carries with it an air of irrational zeal, and seems calculated only for the erudite.

The same unhappy fate was borne by Jerome of Prague, his intimate companion, who attended the council, in order to support his perfecuted friend. Jerome, indeed, was terrified into temporary submission; but he afterwards refused his recantation, and maintained the opinions, which he had for a while deserted through fear, in the 1537, in which he expired the 30th of May, 1416. See Jerome.

The disciples of Hus adhered to their master's doctrine after his death with a zeal which broke out into an open war, that was carried on with the most savage and unparalleled barbarity. John Ziska, a Bohemian knight, in 1420, put himself at the head of the Hussites, who were now become a very considerable party, and threw off the despotick yoke of Sigismund, who had treated their brethren in the most barbarous manner. Ziska was succeeded by Prokopius, in the year 1424. The acts of barbarity that were committed on both sides were shocking and horrible, beyond expression; for notwithstanding the irreconcilable opposition between the religious sentiments of the contending parties, they both agreed in this one horrible principle, that it was innocent and lawful to persecute and extirpate with fire and sword the enemies of the true religion; and such they reciprocally applied to each other. These comotions in a great measure subsided by the interference of the council of Basil, in the year 1433.

The Hussites, who were divided into two parties, viz. the Calixtines and Taborites, spread over all Bohemia and Hungary, and even Silesia and Poland; and there are some remains of them still subsisting in all those parts. More's's Eccl. Hist. vol. iii. p. 447-448, &c. Eng. ed. 8vo. 1795. Cipriani, Lives of John Hus.

HUSUNABAD, in Geography, a town of Bengal; 15 miles W. of Dacca.

HUSUN-ABDAL, a town of Hindostan, in Lahore, 130 miles N. W. of Lahore. N. lat. 33°. E. long. 71°. 45'.

HUSTINGS. See Court of Husting.

HUSUM, in Geography, a sea-port town of Denmark, on the W. coast of the duchy of Sleswick, constituted a city in the year 1608, formerly famous for exporting great quantities of malt. It was also famous for the oyster trade. The chief commerce at present consists in beer, cattle, and horses; 18 miles W. of Sleswick. N. lat. 54° 32'. E. long. 9° 6'.

HUSWA, a town of Hindostan; 20 miles N. W. of Allâhâbad.

HUT, or HUTT, from the Saxon buta, a small cottage or hovel. The word is also used for the soldiers' lodges in the field; otherwise called barracks or cafem.

HUT, in Rural Economy, the common name of a low fort of building of the cottage kind generally constructed of an earthen fort of material, such as strong loamy clay, &c. A number of huts of this description have within these few years been built on the borders of the South Esk river in Scotland, which have a very neat and rural appearance, affording the idea, at a distance, of their being formed of a kind of brown brick-work.

In this case the composition of the materials which are employed is a fort of muddy clay blended with the roots of plants of the aquatic kind, which are dug out of the flood mark of the river, in such sizes and shapes as may be suitable for the purpose that is intended. The pieces or peats, as they are there called, are generally cut out in the form of bricks, but somewhat larger, being prepared in every respect in the manner of peat-fuel. It is usual, in some cases, to build these huts with lime-mortar, but more commonly with clay only.

These huts are usually preferred by the cottagers to those which are built of stone, being warmer, and not much less durable.

It seems not improbable but that a similar fort of material for building this fort of cottages may be met with in many situations.
situations where it has not yet been discovered, and be made use of in this way as well as for fences of the wall kind. See cottage.

HUTA, a town of Lithuania, in the patliniate of Novogrodek; 40 miles E. N. E. of Novogrodek.

HUTCH, among farmers, denotes a vessel or particular place in which to lay corn; also, a kind of hollow trap for the taking of weasels or other vermin alive; and it also signifies a sort of cage, formed of boards and slips of wood, opening in front, and divided within for keeping and breeding rabbits.

HUTCHISON, Francis, in Biography, an elegant writer and ingenious philosopher, born of a diverting miner in the north of Ireland, was born on the eighth of August, 1694. After receiving a proper education at a grammar school, he was sent to an academy to begin his philosophical course. In 1710 he was entered a student at the university of Glasgow, in Scotland, where he renewed his application to the study of the languages, but chiefly devoted himself to the divinity course. After spending six years in the university of Glasgow, he returned to his native country, and undertook the care of an academy at Dublin. Scarcely had he fixed himself in that city, when his accomplishments and talents attracted the general notice of persons of all ranks who had any taste for literature. Lord Viscount Moleworth took much delight in his conversation, and is said to have allowed him with his criticisms and observations upon his "Enquiry into the Ideas of Beauty and Virtue," before it was committed to the press. He received a similar favour from Dr. Synge, lord bishop of Elphin, with whom he lived in habits of great friendship. The first edition of this work made its appearance anonymously, but its great merit did not suffer the author to remain long concealed. Lord Granville, the lord lieutenant, sent his secretary to inquire at the booksellers for the author, and when he could not learn his name, he left a letter to be conveyed to him, in consequence of which he soon became acquainted with his excellency, and was ever after treated by him with distinguished marks of familiarity and esteem. From this time his acquaintance began to be still more courted by men of distinction, either for action or literature; among these was the celebrated archbishop King, who screened him from two attempts made to prosecute him, for venturing to take upon himself the education of youth without having first subscribed the ecclesiastical canons. In the year 1728, Mr. Hutchison published "A Treatise on the Palms." Having conducted his private academy in Dublin for several years with reputation and success, he was invited into Scotland in 1729, to fill the chair of professor of philosophy in the university of Glasgow. Here he spent the remainder of his life, in a manner highly honourable to himself and useful to the university of which he was a member. About this time the degree of doctor of laws was conferred upon him. At Glasgow his time was divided between his studies and the duties of his office. He was in every respect a valuable member of the university, his abilities qualifying him, and his zeal in promoting him, on all occasions, to promote its civil and literary interests. His constitution seemed to promise his friends a long enjoyment of his valuable life, but a sudden attack terminated it in 1747, in the 53d year of his age. His son, published, from the original MSS. of his father, a "Syllem of Moral Philosophy," in 2 vol. 4to. In this work the author endeavours to unfold the principles of the human mind, as united in a moral constitution, and from thence to point out the origin of our ideas of moral good and evil, and of our sense of duty, or moral obligation; he next enquires what must be the supreme happiness of a species constituted as mankind are, after which he deduces the particular laws of nature, or rules necessary to be observed for promoting the general good in our common intercourse with one another as members of society. Dr. Hutchison was of that class of philosophers, who deduce all moral ideas from what they call a moral sense, implanted in our natures, or an inherent sense of right and wrong, which, independently of all arguments taken from the reasonableness and advantages of any action, leads us to perform it ourselves, or to approve it when performed by others. This moral sense they maintain to be the very foundation of virtue. Dr. Hutchison was a man of considerable learning. He was not only acquainted with those subjects most intimately acquainted with his profession, but was a good mathematician and natural philosopher; and was desirous of applying all his knowledge to the grand purpose of establishing the truths of the existence, the perfections and government of God.

HUTCHINS, John, was born in 1698, at Bradford-Peverell, in Dorsetshire, and educated at Bath-college, Oxford, for the church. He took orders, and was presented successively to different livings, the last of which was the rectory of the church of the Holy Trinity, at Wareham. He died in June 1773. He was author of the History and Antiquities of the County of Dorset, which he nearly forty years in compiling, and which, though he lived to see it put to press, was not published till 1774, when it was given to the world for the benefit of his widow and children. It was comprised in two volumesfolio, and is adorned with many plates contributed by the patrons of the work.

HUTCHINSONIANS in Eclectic History, a kind of cabalistic sect, that sprung up in this country towards the beginning of the last century, and that derived its name from John Hutchinson, who was born in Yorkshire, A. D. 1674. Having been educated in his father's house, with a view to the office of steward to some gentleman or nobleman, he was advanced at an early period of life to this station in the service of the duke of Somerset; and his business calling him to London about the year 1700, he became acquainted with Dr. Woodward, who employed him in making that large and noble collection of books, &c. which the doctor bequeathed to the university of Cambridge. Mr. Hutchinson, being desirous of prosecuting his literary studies, begged leave to quit the service of the duke, who appointed him his riding-purveyor, with a fixed salary of 200l. per annum; and this place he enjoyed till his death in 1737. In 1724 he published the first part of his Motes's Pracis, in which he ridiculed Dr. Woodward's Natural History of the Earth, and his account of the settlement of the several strata, shells, and nodules, by the law of gravity; attempting also, with no small degree of prelumption, to refute and explode Newton's theory of gravitation; and from this time to his death he continued publishing a volume every year, or every other year; which, with the manuscripts left behind, were published in 1748, in twelve volumes octavo, by the Rev. Julius Tate, a famous advocate for his doctrine: an abridgment of his works was also published in 1752. In 1712, Mr. Hutchinson completed a machine of the watch kind for the discovery of the longitude at sea, which is said to have been so contrived, that the firing, wheels, and pivots, &c. were not in any considerable degree influenced by heat, cold, moisture, and draughts, and to be capable of that degree of exactness which is requisite for the purpose. Having obtained the testimonials of Newton, and some others to whom it was referred for examination, expressing their opinion of its excellence and utility, application was made for a parliamentary reward, but the author, exasperated at his disappointment,
relinquished his pursuits of this kind, and destroyed all his papers. In 1727, he published the second part of Mofes's Principles, containing the principles, as he apprehends, of the scripture philosophy, which are, a planar, and the air. The same he proposes to exhibit in three conditions, viz. fire, light, and spirit; the two latter are the finer and grofer parts of the air in motion; from the earth to the sun, or from the sun to the earth; there is finer and finer, till it becomes pure light near the confines of the sun, and fire in the orb of the sun, or focal focus. From the earth, towards the circumference of this system, in which he includes the fixed stars, the air becomes grofer and grofer, till it becomes turgid and flagrant, in which condition it is at the utmost verge of this system; from whence, he says, the expression of "outer darknes, and blackness of darknes," used in the New Testament, seems to be taken. The sun, which he places in the centre, is the active vivifying agent, which, by melting the spirit or grofer parts of the air into atoms or finer parts, or other, sets the machine forward and keeps it going; for the light is precluded by the influx of spirit, and the spirit is precluded by the influx of light; and thus the whole matter of the heavens or air is perpetually changing conditions and circulating. In the introduction to this work, Mr. Hutchin- fon intimated, that the idea of the Trinity was to be taken from the three grand agents in the system of nature, fire, light, and spirit; which are three conditions of one and the same substance, and wonderfully answer in a typical or symbolic manner to the three persons of one and the same essence. He also discovers the doctrine in the term cherubim, which is derived from ג"כ, fat, denoting fatness or resemblance, and א"פר, plural of א"פר, a great or mighty one; and to the cherubim, כ"ק. The finitude of the great ones, were represented by a bull: the chief of the same animals, the lion: the chief of the wild, and the eagle of the winged; and these were again the figures of the celestial cherubim, or fire, light, and spirit. The bodies of these three animals were all joined in one, in order to signify the unity of the essence, and the distinction of the persons, and man taken into the essence by his personal union with the second person, whose constant emblem was the lion; and Mr. Hutchinson contends, that the very name of the figure was an hiero-plotical representation of the Trinity. The same doctrine is also taught by the word א"ל, translated heavens; but which the Hutchinsonians suppose to signify names, being, as they say, the plural of א"ל, a name; and the heavens, according to them, are called names; because the material heaven, having in its one substance three conditions of fire, light, and spirit, is the proper name or representation of the Deity in its unity of essence, and trinity of persons; or of the א"ל א"ל, Elohim, or Aîm, which they derive from א"ל, a name, or conditional imprecation, and therefore, must signify persons that have bound themselves by an indispensable obligation; hereby intimating that the three persons of the Godhead have absolutely covenanted together to redeem man. On this account the angelic Jehovah, א"ל, the essence-exist, is so commonly found in conjunction with the plural Aîm, כ"ק, the confederates or associates. They derive א"ל, Eloah, also from the same root, and translate it the accursed one, referring to Christ, who was really made a curse for us. The word א"ל, which we translate covenant, they derive from א"ל, to purify, and render purifier; and thus א"ל א"ל, which is commonly rendered to make a covenant, they translate to cut off the purifier. In this way Mr. Hutchinson and his followers have founded their whole system of theology and philosophy on a forced and fanciful etymology of Hebrew words; indulging their minds in all the wildfashions of imagination and unbounded whim, making words signify what they please, turning the plainest history into sublime prophecy, and contraining sentences to be circular in various ways, and meanings which they were never designed to bear, and which they are incapable of bearing. The scriptures, according to this author, written in Hebrew without points, which is the language framed in Paradize, and in each root of which represents some obvious idea of action or condition, raised by the finitude object which it expresses, and farther designed to signify spiritual or mental things: the Hebrew scriptures, he says, rightly translated and understood, comprise a perfect system of natural philosophy, theology, and religion. Mr. Hutchinson expressly says, that as God was primarily represented by the heavens, to emblems or draughts of these, or descriptions in Hebrew words, were no more than copies of the archetype; and thus the knowledge of the Aîm is derived from the light of nature, not as that phrase is vulgarly understood, by any innate or inbred power in man, but by the immediate influence of the Moi High, the a benefactors and all the Lord of nature. The Greek, he says, that language of erring heathens, because of necessary and to the apostles, to spread the history of facts, which it behoved all men to be apprized of; but Christ and his disciples knew too well its imperfection and finitude to give juli ideas of the divine economy to make use of it for that purpose. The original scriptures in Hebrew were distinct permanent evidence; to these references are always made, and there complete satisfaction is to be found. He also observes, that as the material machine is primarily fitted to the service of the body, so its secondary, but most important use, is to transfix up ideas for the immortal soul, by ascribing and evidences of the otherwise unutterable attributes of the Deity. Hence it must follow, that the language of scripture, which is admirably adapted to convey true and literal descriptions, will also in many places require an emblematical or spiritual interpretation, corresponding to the circumstances of that creature who has a suf of eyes to provide for. The Hutchinsonians not only erect their fanciful system of theological and philosophical opinions on the contrivance of roots and symbols, to the ruin of natural religion and morality, but they loudly declaim against human learning and reason; and they expressly call abstrac reasoning the very province of the devil.

The reader may find a distinct and comprehensive account of the Hutchinsonian system in a book, entitled "Thoughts concerning Religion, &c." printed at Edinburgh, 1743; and in a Letter to a Bishop, annexed to it, first printed in 1732.

It is not improbable that Mr. Hutchinson's death was hastened by too intense an application to his studies; for neglecting his usual summer excursion in 1737, in order to complete a work which he was preparing for the press, he became unable to resist the attack of a bilious fever, to which he fell a sacrifice, notwithstanding the advice of Sir Edward Wilmot and Dr. Mead, in the 63rd year of his age. His judgment seems to have been much inferior to his learning, and his temper appears from the tenor of some of his publications to have been irritable and dogmatical.

HUT, in Geography, a town of Hungary; 12 miles S.S.E. of Czakau.

HUTOW, a town of Lithuania, in the palatinate of Brzez; 28 miles W.S.W. of Pnisk.

HUTTEN, Ulric de, in Biography, one of the early reformers, was the son of a Francian gentleman, and was born.
HUX

born in 1488. He studied at the university of Frankfort on the Oder, where he took the degree of M. A. Being a delinquent of patrimony, he entered into the army of the emperor in Italy, and was at the siege of Parma. He afterwards maintained himself by teaching at Ratisbon, and made himself known by some publications. At the command of his father he attempted to study the law, but finding the profession ill accord with his temper, he enlisted in the army again and served in Italy. He was a man of great courage, and in 1515, learning that his cousin John Hutten, marshal to the court of the duke of Wirtemberg, had been killed by that prince, he drew his pen in his kinsman's cause, and published some very severe harangues against the duke, which have been compared for eloquence and bitterness to Cicero's Cautilianian orations. After attacking the duke with his pen, he employed his arms against him in a war which drove him from his dominions. Having become a professed to the opinions of Luther, he published the bull of pope Leo X. against that re-former, with marginal remarks, in which he treated the holy pontiff with so little respect, that orders were transmitted from Rome to the elector of Mentz to send Hutten thither in fetters. He was on this occasion obliged to quit Mentz, but such was the vigour of his spirit, that he wrote a letter to the elector in which was the following passage: "If you burn my books, I will burn your towns." He afterwards wandered from place to place, and was at Basf in 1523, where the senate made him a considerable present. He received, however, the mortification of having his visit refused by Erasmus, then residing in that city. Hutten was indignant at this treatment, and wrote a book against Erasmus, which that learned man answered. Some farther quarrels drove him from Basf, and he took refuge in the isle of Uffano, in the lake of Zurich, where he died in 1525, in the 56th year of his age. He was considered as a man of learning, and published various Latin works in prose and verse. He edited two new books of Livy, and discovered some MSS. of Pliny, Quintilian, and Marcellinus. Morei.

HUTTER, Elias, was born at Ulm in 1553, and died at Nuremberg about the year 1609. He published an edition of the Hebrew Bible, entitled "Via Sanæa, sive Bibliæ Sacrae Hebrewae Veteris Testamenti." At the end is given the 116th Psalm in thirty different languages. He also published two polyglots of the Bible; one at Hamburg in 1596, in Hebrew, Greek, Latin, and German; and the other at Nuremberg in 1599; and in the following year he published a polyglot of the New Testament in twelve languages. Bayle.

HUTTING OF GRAIN, the name of a practice employed in some places in the northern part of the kingdom, for preserving the corn in wet bad harvest-conditions. See HARVESTING.

HUTTWEIL, in Geography, a town of Switzerland, in the canton of Berne, on the frontiers of Lucerne; 22 miles N.W. of Lucerne.

HUTTYBARRY, a town of Bengal; 45 miles S.E. of Nattore.

HUXHAM, John, in Biography, a physician of considerable reputation, who practised his profession at Plymouth, where he died in the year 1763. It is remarkable, that no biographical memoirs of this able and learned practitioner are extant. His writings display a most intimate acquaintance with the writings of the ancients, and a great veneration for those of Hippocrates in particular; and he quotes the ancient languages, and writes the Latin with great fluency and familiarity. He appears to have spent his life at Plymouth in the active exercise of his profession; for he kept a register of the state of health and reigning diseases at that place, together with an account of the variety of the fevers, for nearly 30 years (namely, from the year 1724 to 1752 inclusive); which were published in Latin, under the title of "Observationes de Aere Morbis Epidemicis, &c." in 3 vols. 8vo. The first of these volumes commences with an account of the year 1728; but in the dedication to Sir Hans Sloane, he refers to an account of the constitution and diseases of the fevers, from 1724 to 1727 already published. The third volume was edited in 1770, after the death of the author, by his son, J. Cor. Huxham, A. M. F. R. S. who, it is to be regretted, did not inherit any memoirs of his father's life.

Dr. Huxham was, at an early period, elected a member of the Royal Society, and communicated several papers on the subjects of pathology and morbid anatomy, which were published in the Philosophical Transactions. But the work upon which his reputation principally rests, is his "Essay on Fevers," published about the year 1759, of which a fifth edition appeared the year before his death, containing also "A Dissertation on the Malignant, Uterous Sore Throat." His accuracy and acuteness, as an observer of the phenomena of disease, were particularly exemplified in his discriminative history of the "Slow Nervous Fever," to which his name is often annexed, when this fever is mentioned by succeeding authors. His theory was the ancient humoral pathology, which much influenced his practice; but that was the general fault of the age. He was the author of some "Observations on Antimony," 4to. 1756; and was elected a fellow of the Royal College of Physicians at Edinburgh. He has given few preface-to his works; for he oberves, with Hippocrates, that the physician, who knows a disease, cannot be at a loss in respect to the form of his remedy; but, having mentioned a favourite formula for the preparation of a tincture of the Peruvian bark, in his Essay on Fevers, in which the bitter is corrected by aromatics, his name has become attached to the tincture of bark, which is commonly prepared in the shops according to his prescription, which is also adopted in the Pharmacopoeia of the College of Physicians. See the works of Huxham.

HUXING of PINK, among Fishermen, a particular method of catching that fish.

For this purpose, they take thirty or forty, as large bladders as they can get; blow them up, and tie them close and strong, and at the mouth of each tie a line, longer or shorter, according to the depth of the water. At the end of the line is fastened an armed hook, artfully baited; and thus they are put into water with the advantage of the wind, that they may gently move up and down the pond. When a muller pike has struck himself, it affords great entertainment to see him bounce about in the water with a bladder fastened to him; at last, when they perceive him almost spent, they take him up.

HUY, in Geography, a town of France, and principal place of a district in the department of the Ourc, situated on the Meuse, which divides it into two parts; 12 miles S.S.W. of Liege. N. lat. 50 ° 31'; E. long. 5° 15'. The place contains, 4871, and the canton, 10,674 inhabitants, on a territory of 116 square kilometres, in 12 communes.

HUYGENS, CHRISTIAN, in Biography, was born at the Hague in the year 1629. He was educated chiefly under his father, and exhibited very rare talents at an early age. At thirteen years of age he was a good mathematician, and began to study mechanics, having discovered a marked genius for that branch of learning, and was encouraged by his great curiosity in examining different kinds of machines and pieces of mechanism. In the year 1645 he was sent to the university of Leyden to study
HUYGENS

fully law; but this pursuit did not prevent him from going on with his mathematical pursuits. At the end of one year he removed from Leyden to Breda, where an university had been recently founded, the direction of which was given to his father. In 1651 he published the first fruits of his studies, in a treatise entitled "Theoremata de Quadratura Hyperboles, Elohias, et Circuli, ex dato Portionum Gravitas Centror, &c," and in 1654 he gave the world another work, "De circuli magnitudine inventa: accedunt Problematum quadrangulorum illiusdem Contractiones." In the following year he was admitted to the degree of doctor of laws at Angers. In 1657, Dr. Huygens published a short piece, entitled "De Rationibus in Lando Alta," annexed to a mathematical work of professor Schooten's, in order to shew the usefulness of algebra. In the same year he printed his "Brevis Institutione de Ufii Horologiorn ad innvenientias Longitudinis." An attempt was made to deprive him of the honour of the discovery, which obliged him to publish another piece to shew that his pendulum was very different from that invented by Galileo. This philosopher, in the course of his observations on the planet Saturn, had discovered what he imagined to be two satellites, almost in contact with his body, which some time after disappeared. Huygens, being desirous to account for these appearances and changes, applied himself to the improvement of the telescope, and he contrived one possessing a higher power than any which had been before invented. With this he discovered the ring, and he ascertained that the appearances which Galileo had taken for satellites were only Anie, or the external parts of the ring. He also discovered a satellite belonging to that planet which had never been seen before. These discoveries he communicated to the world in a work entitled "Sylvaeani Saturnian i.e de Cavitatis mirandorum Saturni Phænomenon, et Comite ejus Planetæ novo." In the year 1660 he came to England, where he communicated his art of polishing glasses for telescopes, and was admitted a member of the Royal Society. Here he made considerable improvements in the air-pump, and discovered the laws of the collision of elastic bodies. In 1663 he was invited by the minister Colbert to settle at Paris; the offer of a handsome pension in the king's name induced him to accede to the minister's proposal, and he resided at Paris from 1665 to 1681, where he was admitted a member of the Academy of Sciences. In 1673 he published "Horologium Oscillatorium; i.e de motu Pendulorum ad horologia apptato, Demonstrationes Geometrica:" discovering a method of rendering clocks exact, by applying the pendulum, and of rendering all its vibrations equal by the cycloid. In consequence of the revolution of the edict of Nantes he determined to leave France, though every effort was made to prevail upon him to remain there. Nothing he said should induce him to live in a country where his religion was proscribed, and its professors harassed by the most cruel persecutions. He accordingly quitted Paris, and returned to Holland, where he spent the remainder of his life in scientific pursuits and employments. His last work, and which he did not live to see through the press, was a treatise on the plurality of worlds, and the probability that the planets are inhabited. Huygens died in 1695, when he was in the 67th year of his age. He was, unquestionably, one of the ablest mathematicians of the age. His temper was cheerful, his manners amiable, and he was in all respects a good man. Many of his works were published after his death. Moretti.

This great mathematician seems to have been as well acquainted with practical music, as the philosophy of sound. Dr. Smith, in his Harmonics, quotes his authority for an observation which could only be made by a very nice and practised ear.

M. Huygens observed long ago, "that no single voice, or perfect instrument, can always proceed by perfect intervals, without erring from the pitch at first assumed; as in singing: the founds in the base C, D, E, G, C, the voice would sink infinitely so much, that the last C would be considerably lower than the first."

Because of those perfect intervals, which are as 4 to 3, 5 to 6, 4 to 5, 2 to 3, an account is made, in such a proportion, as 165 to 163, that is, as 80 to 81, which is what calculators call a comma. Corroborato, lib. i. p. 77.

This, says Dr. Smith, is also confirmed by what we are told of a monk, who found by subtracting all the affections of the voice in a certain chant from all its descents, that the latter exceeded the former by two commas; so that if the ascents and descents were constantly made by perfect intervals, and the chant were repeated but four or five times, the final found, which in that chant should be the same as the initial, would fall about a whole tone below it.

We have always found ourselves, that voices, singing without an organ or instrumental accompaniment, gradually sink to a lower pitch than that in which they began. And in singing a ballad with many different slants to the same air, the depression is proportionally considerable. But Huygens has assigned a scientific reason for the defect. Dr. Smith frequently refers in his Harmonics to the Cycloides Harmonicae of Huygens at the end of his works, or in PHilosophie des Ouvrages des Scavans, October, 1691.

HUYGENS, GOMARUS, was born at Liére, in the territory of Antwerp, in the year 1631. He was educated at the university of Louvain, where he was so much distinguished among his contemporaries, that he was appointed professor of philosophy when he was only twenty-one years of age. In 1668 he began to confine his studies solely to divinity, and in the same year was admitted doctor, and deputed to proceed to Rome, to defend the privileges of the university of Louvain before pope Clement X. Having succeeded in his object he returned to Louvain, where he was incessantly employed in his studies till the year 1677, when he was appointed president of the college by pope Adrian VI. In the year 1682, his Catholic majesty, without solicitation, belloved on him the canonry of St. Peter, at Louvain. Soon after this he was involved in disputes with the Jesuits, and his enemies procured an interdict against him, by which he was prohibited the exercise of his functions as president, preacher, and confessor. Both parties appealed to the pope, who decided in favour of Huygens. A temporary peace was produced among the several combatants, during which Mr. H. died in 1702, at the age of 71. He was author of many theological works, among which are his "Breves Observationes," which, notwithstanding the title, are extended to fifteen volumes, 12mo. Moretti.

HUYGENS'S TEMPERAMENT OF THE MUSICAL SCALE. In his Cycloides Harmonicae, at the end of his works, and in Hist. des Ouvrages des Scavans, 1691, p. 78. M. Huygens adopts a syllable of temperament of the musical scale, in which the octave is divided into 73 equal parts, whereas the mean tone is 5, and the major limina 3. Dr. Robert Smith, in his Harmonics, 2d edit. p. 158, calculates the temperaments of the Vth, IIId, and VIIth in this syllable, and Mr. Fary has done the fame in speculum 12 to his Theorems, Phil. Mag. vol. xxxvi p. 52. where it appears, that the fifths in this syllable are each flattened 2.4543 Σ, each major third is sharpened 1.4065 Σ, and each major sixth is also sharpened 3.0524 Σ. At page 224. Dr. Smith gives the lengths of a monochord string for each of the 21 notes of this scale, for instruments with
with notes sufficient, and which will equally serve for tuning the common doutrine instruments, by taking the seven natural notes C, D, E, &c. and C, E, &c. from the short keys of the instrument. And at page 207 he shews, that by help of the first table of beats in plate 20, answering to the pitch 262, (that being nearly 3d of a mean tone, or 4,71542) lower than our present Composer pitch, see that article; this system may be tuned, on common, or on more perfect instruments. In 1725 Ambrose Warren published a thin quarto, under the title of the "Tempometer," wherein he pretends to the discovery of this system of 51 intervals in the octave, but which he more probably took from our author, as Mr. Farey has remarked in the page of the Phil. Mag. above referred to.

HUYSSAN, or HOUSEMAN, CORNELIUS, in Biography, a painter, born at Antwerp in 1628. He studied the art under Gaspar de Wit, but seeing some of the works of Artois, he was so struck with them that he went to Brussels to place himself under him.

In some time he copied his manner, but afterwards adopted one of his own, yet retained somewhat of Artois, with a mixture of the taste of the Italian schools, and he is considered as one of the best landscape painters of the Flemish school. He died in 1727, aged 70.

HUYSSUM, JOHN VAN. This illustrious painter hath surpassed all who have ever painted in that style; and his works excite as much surprise by their finish so as to excite admiration by their truth.

He was born at Amsterdam in 1652, and was a disciple of Julius Van Huyfum, his father. He set out in his profession with a most commendable principle, not so much to paint for the acquisition of money, as of fame; and therefore he did not aim at reputation and at delicacy, and if possible, to arrive at perfection in his art. Having attentively studied the pictures of Mignon, and all other artists of distinction who had painted in his own style, he tried, in every manner that would form him to imitate the lightness and singular beauty of each flower, fruit, or plant; and then fixed on a manner peculiar to himself, which seems almost inimitable. He soon received the most deferred applause from the ablest judges of painting; even those who furnished him with the loveliest flowers, confessing that there was something in his colouring and pencilling that rendered every object more beautiful, if possible, than even nature itself. His pictures are finished with incomparable truth; for he painted every thing after nature, and was so regularly exact, as to watch even the honey of the bee in its season of apple blossom; no persons who possessed such a knowledge of nature could pretend to become purchasers. Six of his paintings were sold, at a public sale in Holland, for prices that were almost incredible. One of them, a flower-piece, saw for fourteen hundred and fifty guilders; a fruit-piece, for a thousand and five guilders; and the smaller pictures for nine hundred.

The vass farms which Van Huyfum received for his works, caused him to make his advantages to exceed; no person was admitted into his room while he was painting, not even his brothers; and the method of mixing the tints, and preserving the lujure of his colours, was an impenetrable secret which he never would disclose. Yet his conduct is certainly not to his honour; but rather an argument of a low mind, fearful of being equalled or surpassed. From the same principle he never took any disciples, except one lady, named Haverman, and he grew envious and jealous even of her merit.

By several domestic disciples his temper became changed; he grew morose,自此, and apt to withdraw himself from society. He had many envious of his fame, which had ever been the fevere lot of the most deserving in all professions; but he continued to work, and his reputation never diminished. It is universally agreed, that he has excelled all who have painted fruit and flowers before him, by the confessed superiority of his touch, by the delicacy of his pencil, and by an amazing manner of finishing; nor does it appear probable that any future artist will ever become his competitor. The care which he took to purify his oils, and prepare his colours, and the various experiments he made to discover the most lustrous and durable, is another instance of his extraordinary care and capacity.

From having observed some of his works that were perfectly finished, some only half finished, and others only begun, the principles by which he conducted himself may perhaps be discoverable. His cloths were prepared with the greatest care, and pruned with white, with a perfect purity, to prevent his colours from being obscured, as he laid them on very lightly. He glazed all other colours, except the clear and transparent, not omitting even the white ones, till he found the exact tone of the colour; and after he had finished the forms, the lights, the shadows, and the reflections; which are all executed with precision and warmth, without dryness or negligence. The greatest truth, united with the greatest brilliancy, and a velvet lustre on the surface of his objects, are visible in every part of his compositions; and as to his touch, it looks like the pencil of nature.

Whenever he represented flowers placed in vases, he always painted those vases after some elegant model, and the base-work is as exquisitely finished as any of the other parts. Through the whole he flowed a delicate composition, a fine harmony, and a soft happy effect of light and shadow. Those pictures which he painted on a clear ground, are preferred to others of his hands, as having greater lustre; and as they demanded more care and exactness in the finishing; yet there are none on a darkish ground, in which appears rather more force and harmony.

It is observed of him, that in the grouping of his flowers, he generally designed those which were brightest in the centre, and gradually decreased the force of his colour from the centre to the extremities. The birds’ nests and their eggs, the feathers, insects, and drops of dew, are expressed with the utmost truth, so as even to deceive the spectator. And yet, after all this merited and just praise, it cannot but be confessed, that sometimes his flowers appear like wax or ivory, without that peculiar luster and warmth which is constantly observable in nature.

Befide his merit as a flower-painter, he also painted landscapes with great applause. They are well composed; and although he had never seen Rome, he adorned his scenes with the noble remains of ancient magnificence which are in that city. His pictures in that style are well coloured, and every tree is distinguished by a touch that is proper for the leafing. The grounds are well broken, and disposed with taste and judgment; the figures are delineated in the manner of Laforge, highly finished, and touched with a great deal of spirit; and through the whole composition, the scene represents Italy, in the trees, the clouds, and the skies. He died in 1749, aged 67. Fulkington’s Dict.

HUZANKA,
HYA

HUZANKA, in Geography, a town of Lithuania, in the
pratinate of Novogrodek; 36 miles S.E. of Novogrodek.

HUZZARD, in Mining, signifies ochry, foul, or bad;
as hazzard lindesone in Derbyshire, is the ochry and cherty
mixtures of stone found in the rocks where they skirt the
veins, and in the Inny lenticular masses, found in the veins
called Riders, which see. Sometimes this kind of stone, unfit
for lime-burning, is called ballad-lindesome.

HWARE, in Geography, a town of Sweden, in West
Gotland; 63 miles E. of Uddevalla.

HWEN, a town of Sweden, in the fertile island of Sweden, to
which country it was granted by the treaty of Roschild, in
1658; situated in the Sound, about 8160 paces in circuit,
and having at a distance the appearance of a high mountain.
This island was granted by Frederick II. king of Denmark,
to Tycho Brahe (see Brahe). The whole island contains
but one parish, or village, with about 50 houses; 15 miles
N. of Copenhagen. N. lat. 55° 54'. E. long. 12° 42'.

HWITITTIS, a town of Sweden, in the government of
Abo; 15 miles N. of Birnome.

HYACINTH, in Botany. See Hyacinthus.

HYACINTHUS. See Crinum.

HYACINTHUS, Grape. See Hyacinthus.

HYACINTHUS, Lily and Saffron. See Scilla.

HYACINTHUS, Tuberose. See Polyanthus.

HYACINTHUS, in Natural History. See Gems and Zircon.

HYACINTHIA, in Antiquity, feasts held at Sparta in
honour of Apollo, and in commemoration of his favourite
Hyacinth.

This Hyacinth was the son of Amyclas, king of Sparta,
and was beloved both by Apollo and Zephyrus. The youth
showing most inclination to the former, his rival grew jealous;
and to be revenged, one day, as Apollo was playing at the
discus, &c. quoits, with Hyacinth, Zephyrus turned
the direction of a quoit which Apollo had pitched, full upon
the head of the unhappy Hyacinth, who fell down dead.
Apollo then transformed him into a flower of the same
name; and, as a further token of respect, they say, com-
manded this seal. The Hyacinthia lasted three days; the
first and third whereof were employed in bewailing the death
of Hyacinth, and the second in feasting and rejoicing.

The persons who afflicted the ceremony were crowned
with ivy: because, says Vossius, De Idolol. lib. ii. cap. 14.
Bacchus and Apollo were the same person.

HYACINTHUS, in Botany, Ιδαν. 250.; a name adopted
from the ancient Greeks, who applied it to the flower
hoped to have sprung from the blood of Hyacinthus, the
favourite of Apollo, when accidentally slain. Great
differences have arisen amongst commentators concerning
the plant of the ancients, which we cannot induce to
effect, but there seems no paramount authority for the pre-
fence application of the name in question.—Linn. Gen. 170.
mark. Ill. t. 238. Class and order, Hexandria Monog.

Gen. Ch. Cal. none. Cor. of one petal, bell-shaped;
its limb in five reflexed segments. Nectary three pores near
the summit of the germen. Stam. Filaments five, awl-shaped,
uniform, shorter than the corolla, inserted into the tube;
anthers approaching each other. Pijl. German superior,
roundish, with three angles and three furrows; style filiform,
shorter than the corolla; stigma obtuse. Peric. Capsule
roundish with three angles, of three cells and three valves.
Seeds mostly two in each cell, roundish.

Eff. Ch. Corolla inferior, of one petal; tube swelling;

VOL. XVIII.

HYA

limb regular, in five segments. Germin with three honey-

Hearth.

Obi. The tube of the corolla, and even its limb, varies
so much in shape, that Tournefort, and recently Mr. Ker,
in Curtis's Botanical Magazine, have divided this genus;
their Muscaris, separated from it, having a globular tube.
In some species, as H. romanus, the limb is more deeply
divided; but in H. no fretus of Linnaeus the corolla is
actually of fix petals, and we therefore preface this species
properly removed, in the Fl. Brit. and English Botany,
t. 377, to Scilla. Considerable doubts have, moreover,
 arisen respecting the melliferous pores described by Linnaeus
upon the germen, which are certainly not discernible in every
one of the species, but indeed they are to be seen at a part-
icular period only in any.

Wilkdenow has thirteen species, of which H. non fretus
is a Scilla, as we have said, and cernus also; but the last of
these may be supplied by two of the Muscaris tribe from
Desfontaines, maritimus and parviflorus.

Fair examples of the genus are the common garden Hya-
cinth, H. orientalis, which numerous and gorgeous varieties
are the delight of florists; see Curt. Mag. t. 937; and
H. amethystinus, prettily figured in Redoutés Liliacees.

H. Muscaris, figured in Curt. Mag. t. 734, and Redouté
Lil. t. 152, a native of the Levant, is hardy in our gar-
dens, and valuable for its delicious musky scent, though
not conspicuous for beauty, its flowers being of a dusky
green.

the Starch Hyacinth, so called from the peculiar smell of
its dark blue flowers, is wild or naturalized on walls or in
sandy fields in England, flowering in May.

H. corymbosus, Linn. Mant. 223, is made a Majonvia
by Mr. Ker, in Curt. Mag. t. 991, but we are at a loss
to understand the reason of this measure, against which
the habit strongly revolt.

HYACINTHUS, in Gardening, comprehends plants of
the bulbous-rooted, flowering, perennial kind; of which the
species principally cultivated are the eastern, or garden-hy-
cinth (H. orientalis); the common hyacinth or harebells
(H. non-scriptus); the bending hyacinth (H. cernus);
the late-flowering hyacinth (H. scorbus); the anthem-
ised hyacinth (H. amethystinus); the musk hyacinth
(H. muscari); the feathered hyacinth (H. monfragus);
the purple grape hyacinth (H. comosus); the blue grape
hyacinth (H. botryoides); and the clustered grape hyacinth
(H. racemosus).

The first species and varieties are the sorts that are the
most usually raised, and esteemed by those engaged in the
culture of flowers.

The varieties of this species are numerous; as those with
fingle white flowers; with double white flowers; with red
fingle and double flowers; with flesh-coloured fingle and
double flowers; with blue fingle and double flowers; with
purple blue-coloured fingle and double flowers; with yellow
flowers; with double white flowers with red eyes or mid-
dles; with double white with purple eyes; with double
white with flesh-coloured eyes; with double white with
yellow eyes; with double agate blue; with double and fingle
porcelain-blue; and with double and fingle violet-coloured
flowers.

And besides, there are 160 a number of intermediate va-
riedes which have been obtained from feed, and by which
many new ones of the chief sorts just noticed are yearly
produced; each being distinguished either by the name of
the place where it was first raised, the person who raised it,
HYACINTHUS.

...that of illustrious personages, such as great kings, generals, poets and historians, as well as gods and goddesses, &c.

The principal circumstances by which the properties of a good double hyacinth are known, are that the stem or stalk be tall, strong, and upright; the flowers or bells sufficiently numerous, each being suspended by a short, strong peduncle, having a horizontal position; the whole presenting a compact pyramidal form, with the crown or uppermost flower perfectly erect: the flowers should be large and well filled with broad, bold petals, appearing to the eye rather convex than flat or hollow; they should extend to about the middle of the scape or stalk. The plain colours should be clear and bright, strong ones being generally preferred to such as are pale, and those which are mixed should blend together in an elegant manner.

In the fifth fort most of the flowers have white stripes and edges; occasionally varying to pure white, and a fine pale red colour, with deeper, coloured veins running along the three outer segments. It was formerly known to gardeners under the title of Coventry blue hyacinth.

The sixth species also affords varieties that have ash-coloured purple flowers on the lower part of the spike, but which are larger and have more of the purple call than in that fort; and those on the upper yellow with a very grateful odour, and with very large yellow flowers.

The eighth fort, which is termed the two-coloured or tassel hyacinth by Mr. Curtis, has varieties with white and blue flowers.

This is esteemed more for its singularity than any beauty it displays.

The ninth species has likewise varieties with blue, with white, and with ash-coloured flowers.

Method of Culture.—The first of these forts and varieties, are all increased by planting the off-frets from the roots, in the manner of other bulbous-rooted perennial plants; and by fowing the seed to produce new varieties of the flowers.

And they succeed best in light, soil, but will prosper in any common earth, particularly in moderate sandy ground, in a dry, open, sunny situation. These bulbs, if planted in strong or very moist land, are apt to rot in winter, or become diseased. Where, therefore, the soil of the flower-borders or beds is of a strong, heavy quality, the part designed for hyacinths should have light materials incorporated with it, such as any light sandy earth, from the surface of some common or other place; drift sea-fand, or any upper sandy soil, or light earthy compot; and where the soil of the borders, &c., is of a very light, sharp, sandy nature, a portion of light, mellow, loamy earth and neat's dung, or well rotted dung of old hot-woods, should be mixed with it, which make a fine compot surface mould for the hyacinth, when blended and laid on long enough before for the dung to be converted into mouldy earth.

The ground should be well worked over as a preparation for the plants, one spade deep at least, raking the bed or border a little above the general level to avoid moisture; and raking the surface as smooth and even as possible.

The florists usually prepare a compot for their rare kinds of hyacinths, with light sandy loam, or any sandy earth from a palture field, taking only the top spit, ten or twelve inches deep, adding about one-third, from the surface, to one of drift or sea-fand, and the same quantity of rotten neat's dung; mixing the whole in a heap ridge-ways, in some dry sunny exposure, to lie several months, or if a year or more the better it will be.

To the above materials some also add a quantity of rotten leaves of trees, thoroughly decayed tanner's bark, or any perfectly rotten earthy wood, or rotten saw-dust; all of which together greatly improve the composition; but as these are not always readily obtained, the other compot is frequently used with success. With these compotts a bed is prepared in the beginning of the spring, four feet wide and two deep, a cavity being dug out that width and depth, and filled up entirely with the composition, six inches above the common level, to allow for settling, leaving it a fortnight or a month to settle; when it is ready for the reception of the bulbs of the plants.

The custom with the curious in these plants, is never to plant the fine forts two years together in the same bed or earth, without some previous renewal, as by planting them every year in a fresh bed, or fresh prepared compot, it greatly improves the size and beauty of the flowers.

The most proper season for planting them is either in October or the beginning of November; as those then planted shoot early in spring, and flower strong at their usual season; but those planted later in autum, or continued out of the ground till January and February, for a late bloom, flower weaker and with inferior beauty; the principal part should always be planted in the autumnal season.

Where any of the common kinds are intended to be planted to adorn the open borders contiguous to the principal walks, or lawns near the habitation, to increase the variety in assemblage with other bulbous-rooted spring flowers, as early tulips, narcissi, or anemones, ranunculuses, &c., they should be disposed towards the front, more or less in a varied order, in patches of three roots in each, three or four inches deep; and the patches may be from about one yard to three or four distance, letting them stand to take their chance, without any further care in their culture.

And in planting the fine double forts, four or five rows may be planted on each bed lengthways, about nine inches distant in each row, and about four inches deep, either in drills the above depth, by dibble, or by bedding them in; and as soon as they are planted in either method, the surface of the bed should be raked smooth and even on the upper side.

The bulbs being thus planted, the chosen forts should be protected in the beds occasionally, during winter, from severe frost. They may be readily protected by a covering of straw, or any kind of dry, strawy litter, three or four inches thick; or by arching the beds with hoops or rods, or with moveable arrows of open-work, covered with mats, the coverings being immediately removed when not wanted. The same caution should be continued in the spring.

When the flower-implies are advanced nearly to their full height, it is proper to support them, by placing a small stick, fifteen or eighteen inches long, close to each plant, being careful not to thrust it into the bulb, and to tie the stems neatly to each stick, by which the spikes of flowers will be preserved in an upright position.

When in bloom, the curious forts may be preferred much longer in beauty, by being screened occasionally from the sun and rain, by an awning or umbrella of mats or canvas; they should, however, be shaded only from the midday sun, from about ten to three or four o'clock, and only from excessive rains and boisterous winds.

But when the flowers begin to fade, all coverings should be entirely removed, that the bulbs and increasing off-frets may derive all possible benefit from the free air, dews, &c. When the season for flowering is over, the bulbs should be taken up, which, in the florist's language, is called lifting the roots. The fine forts should be taken up at this period to separate the off-frets for increase, as well as to benefit
HYACINThus.

benefit the main bulbs, which will always flower stronger than such as are suffered to remain two or more years unremoved.

The proper time for this work is in summer, soon after they have done flowering, when their leaves begin to turn yellow, as then the bulbs have had their full growth for that season, and should by no means remain longer in the ground, as they will rot.

Dry weather should be chosen, and a trowel or small spade is proper for lifting them, taking them up one by one, and breaking off the stem within an inch or two of its origin; then laying them in an airy room, out of the midday sun, to dry off the grafts loosely very gradually, and to ripen the bulbs to a due hardness, when they appear of a purplish tinge, otherwise they are apt to rot and be destroyed.

When the bulbs are properly hardened and ripened, they should be taken up and separated from any off-sorts, well cleared from earth, loose skins, and fibres at bottom; then, after exposing them a few hours to the sun, put in boxes singly or upon dry shelves out of the sun, to remain till the season for planting them again arrives.

All the off-sorts appearing about the main bulbs at the lifting season, are to be carefully separated from them, either as soon as they are taken up, or after the bulbs have lain ripened, being kept separate, and planted in the early autumn, in beds by themselves, in rows six inches asunder, and two or three deep, where they should remain a year or two; then be taken up at the proper lifting season in summer, and managed as the large flowering bulbs.

In raising these bulbs from seed, which is practiced by the curious, to obtain new varieties, to increase their stock; from the time of sowing, it will be for four or five years before the bulbs produce flowers: the seed ripens in the summer, which may easily be faved, by suffering some of the finest single and half doubles to stand and ripen it in perfection. The proper season of fowing it is about the beginning of autumn, in which case the plants will appear in the following spring. It grows perfectly well in a bed or border of light earth in the open ground; but where only a small quantity is to be grown, it may be done in pots or boxes, and be thereby much more convenient to remove into different situations at different seasons, as there may be occasion. Whenever mode is adopted, light rich mould should constantly be chosen for the purpose, the surface being rendered perfectly even and smooth, and the seeds fown with regularity over it, and covered in to the depth of from an inch to an inch and a half. Where fown in pots or boxes, they should be plunged up to their brims in the mould, in some dry situation, and as the winter begins to set in, be removed either under the occasional protection of a hot-bed frame, or be covered with some light dry litter in frothy weather, but letting them be fully exposed whenever it is mild.

As soon as they first appear in the spring, with very small leaves, they should be kept perfectly free from weeds, and have a little fine mould fowed over them in the autumn in the beds, being protected in the winter season as before directed. When their leaves begin to decay in the second summer, the young bulbs should be taken up, and replanted in nursery beds, about the end of July or beginning of the following month, in small drills, two inches in depth, letting them be three or four inches apart. They may remain in this situation two years, only lifting over the surfaces of the beds about half an inch thick for fine mould in the autumn, and giving them occasional protection by coverings or other means, during the winters. After this they are to be managed in the usual manner, being taken up at the general lifting season, and planted out where they are to flower in the autumnal months.

All the other species are capable of being readily increased by planting out the off-sorts in the method that has been already directed, as they each of them afford them in great plenty. They may be taken up every second or third year, at the time the leaves decay, and the off-sorts be separated and managed in the same mode as has been directed for those of the first species.

Method of Blowing the Bulbs in Water-Glaffes, &c. — Bulbs of this sort may be brought to flower in the winter and early spring, by having them put in root-glaffes filled with water, or in pots, or small light boxes filled with sand, or light dry sandy mould, in the beginning of the autumn, and depositing them in a warm room, green or hot-houfe. In all these situations they blow in a highly agreeable manner, and earlier or later in these different seasons, according to the periods at which the bulbs have been introduced and planted.

The sorts of bulbs commonly employed for glaffes and pots, &c. are principally the varieties of the oriental kind, especially where they are to be blown in water. In providing these, care should be taken to select such bulbs as are perfectly sound and firm, having the root part at the bottom full, plump, and solid.

The glaffes for this purpose are of the bottle kind, having straight upright bodies gradually narrowing towards the tops, where they terminate in wide concave mouths, capable of containing one root or bulb in each. They are usually fold at the glaffs-hops, feed-hops, and nurseries, at from about five to nine shillings the dozen. In using them they should be filled with soft clear water up to the necks, and a little way into the cavity of the mouths, one bulb being then placed in each glaff, with the bottom or root part a little in the water, and the top upright, setting them in the window of a room which faces the sun, or upon a chimney-piece, or the shelves of a light room where there is a fire, as the growth of the bulbs is thus greatly promoted. And they soon put forth strong root-fibres into the water, and at the same time push out leaves and flower-buds at the tops, which advance in a regular manner to flowering, in their peculiar habits. It is necessary to renew the water occasionally, as it becomes foul, or affords a factitious smell, by discharging the old, and immediately filling up the glaffes with fresh as is fresh, which is the whole of the trouble that is requisite to their management. As soon as the flalks and flower-spike are advanced to a tolerable height, a neat small flack should be placed to each, as a support to keep it in an upright direction.

But in order to have the bulbs in blow at the most early season, the glaffes that contain them should be placed in a hot-houfe, or other forcing-houfe.

And by planting some bulbs in pots or neat boxes of light sandy earth, or pure sand, in the autumn, and putting them in a warm sitting room, green-houfe, &c. they will flower at an early period.

The bulbs in the glaffes usually flower in about six, eight, or ten weeks, according to the warmth of the situation in which they are placed. And they generally continue in blow for three or four weeks.

Where bulbs of this sort are to be forced by fire or barking heat, some middling small pots should be provided, or small, neat, oblong boxes, six inches in depth, filling them half way, or a little more, with light dry earth, or that of a sandy nature, or with sand, planting one, two, three, or more bulbs in each pot or box, according to the size of them, pressing the bottoms gently into the earth, and filling up with more earth or sand over the crown of the bulbs. After they have been thus planted, the pots or boxes should.
HYÆ

should be placed in the houses, &c. watering the bulbs moderately with soft water, when the earth appears dry. They flower best, when this is repeated, when the flowering is over, and the leaves and leaves are decayed, the old bulbs should be taken up, cleaned and dried; being afterwards planted out in the open ground to recover strength, and produce good effects in the future year.

These are all highly beautiful plants, that afford much ornament and variety in gardens and pleasure-grounds. The more hardly common sorts are proper in the borders, clumps, and other parts towards the fronts; and those of the double and finer kinds, in beds, pots, glasses and boxes, to be set out for variety.

HYADES, "τάξις," from τὰ, to rain, in Astronomy, are seven stars on the bull's head, famous among the poets for the bringing of rain.

The principal of them is in the bull's left eye, by the Arabs called Aldebaran. See Taskis.

The poets feign them to have been the daughters of Atlas and Pleione; and we have the names of six of them, viz. Eudora, Ambrofa, Prodice, Coronis, Philito, and Polifo, others add a seventh, viz. Thione. Their brother Hyas being torn in pieces by a lion, they wept his death with such vehemence, that the gods, in compassion to them, translated them into heaven, and placed them in the Bull's forehead; where, as they say, they continue to weep: this constellation being supposed to prefigure rain.

Others represent the Hyades as Bacchus's nurses, and the fame with the Dodonides, who fearing the reftment of Juno, and flying from the cruelty of king Lycyurgus, were translated by Jupiter into heaven.

It is probable that thefe pretended Hyades, a Greek term signifying rainy, were merely poetical personages, whose names were given to certain stars discovered by Atlas.

HYÆNA, or Hiena, in Natural History, a species of the canis, with a straight annulated tail, and the hairs of the neck long and erect; naked ears, and four toes on each foot. It has fix cutting teeth, and two canine in each jaw; and between the tail, which is short, and the anus, a tranverse orifice. The animal which is known to us by this name is a quadruped almost as large as a wolf, excepting that its legs are not fo long; the hair of it is rough, and its skin spotted with divers colours. Hyænas were formerly produced at Rome in the public games, and they have been repreffed on some medals on account of their rarity. Spanheim, who had copies of it engraved from medals, describes it with the head of a mastiff, with short triangular ears, a lion's tail and feet, and hair spotted all over like a tyger's. It inhabits Asia, Turkey, Syria, Peria, and Barbary.

Pliny's account of this animal is very fabulous. He says, that it changes its sex every year; and that from its eyes are taken precious stones, called hyaenas. Arritotle and Ælian say, that it makes dogs dumb with its shadow; and that it imitates the speech of mankind in order to deceive them, and thus draw them out of their houses and devour them.

The superstitious Arabs carefully bury the head when they kill a hyæna, lest it should be applied to magical purposes, as the neck was old, by the Thessalian forrefters. Lucan. lib. vi. 672.

Buefqueis, in his travels to Amafia, relates several particulars of this animal. He says, it is almoft the shape of a wolf, but not fo tall; that its hair is like that of a wolf, except its being more brilily, and marked at certain places with great black spots; it has no neck, but its head is fastened to the verdabra of the back, fo that it is forced to turn itself quite round, whenever it would look behind. It is very cruel and voracious; it drags dead bodies out of graves, and carries them to its den. It also preys on the hordes and flocks. It is faid to imitate the voice of a man, and that by this means it often deceives travellers. It is a solitary unfociable animal, and inhabits the cafsins of rocks. These animals have a moft malevolent affeét; and they are in their nature cruel, fierce, and untameable.

HYENA, fossul remains of. M. Cuvier, in his Report to the National Institute of France, of the Tranceations of the Physiological and Mathematical Clafs in 1806, mentions, that the bones of hyænas have been found in a great number of caverns in the mountains of Hungary and Germany, in company with the skeletons of tigers, bears, and other animals of unknown species: they are also found in loose recent alluvial sands, in some valleys, he says, in the Report for 1805. Phil. Mag. vol. 35. p. 388.

HYÆNUS LAPIS, the name of a flone faid to be found in the eyes of the hyæna. Pliny tells us, that these creatures were anciently hunted and destroyed for the fake of these flones, and that it was supposed they communicated the gift of prophecy, on being put under the tongue.

HYAGNI, in Greek Mythology, the Oxford marbles tell us, was of Celené, and according to Alexander, cited by Plutarch in his Dialogues, he was the moft ancient perfon on the flute in Greece.

He was contemporary with Eriphon, 1506 years B.C., who instituted the Panathenean games at Athens. He was faid to be the author of the names confecrated to Cybele, to Bacculus, to Pan, and to many other divinities.

He added a fixth ftring to the lyre of Mercury. Some make him the inventor of the Phrygian mode, and double flute. He was the father of Marps, according to Plutarch and Nonnus. Apuleius fays, that he brought the flute to its higheft perfection.

HYALE, in Mythology, one of the nymphs of Diana.

HYALINÆ, in Natural History, derived from τάξις, glaft, the name of a genus of fossils, of the class of the talces, the characters of which are, that they are composed of separate plates, of confiderable thicknefs, and thofe not fufible into any thinner.

There is but one fpecies known of this genus, which is found lodged in the clay, in the fleep banks of the river Aube in Champagne, near the town of Bar, and in fome other places along that river; but fo far as is yet known, in no other part of the world.

HYALINGE, in Geography, a town in Sweden, in the province of Blekingen; 20 miles S. S. E. of Konnbeck.

HYALITE, in Mineralogy, occurs in wacke, in rawiform flaves, and is chiefly found at Frankfurt on the Main. It has a confiderable resemblance to gum, and is nearly allied to opal. The flaves are usually much cracked. Its colour is yellowish and greyifh-white, and it occurs in thin cruits on other minerals. Externally and internally it is finifhing, and its lufure is vitreous. The fracture is small and flat conchoideal. The fragments are indeterminately angular, and sharp edged. It is tranfluent, paffing to semi-transparent. It is intermediate between the hard and femi-hard: it is brittle and frangible. The specific gravity is 2.11. It is infufible at 150° of Wedgwood, but yields to foda. Jameson's Min. Thomson's Chemistry.

HYALOIDES, in the Natural History of the Ancients, the name of a transparent flone fit to engrave leaves on, which were painted on the wine, and most bright and ready reflecting the images of things. We have this flone to this day in many parts of America, particularly about the river of the Amazonas, from whence many fine flones of it have at times been brought, and have been by
HYDAGE. See HIRAGA.

HYBACUS, a term used by the old medicinal writers to signify a quaffy, attended with a dwelling on each side of the throat.

HYARON, in Geography, a small island in the Grecian Archipelago, near the coast of the Morea, between the gulf of Napoli and the gulf of Engia.

HYAT, a town of Hindoostan, in the circuit of Sollapour; 12 miles E. N. E. of Sollapour.

HYATNAGUR, a town of Hindoostan, in Bengal; 18 miles N. W. of Mauldah.

HYBERNICUS LAPIS. See IRISH SLATE.

HYBIA, in Ancient Geography, a town of Sicily; of which Stephanus gives an account, distinguishing three places of this name under the appellations of major, minor, and parasce. The first, or Hybia major, was situated near and south of mount Etna. Panhiamus, in his "Elias," l. i. 15, says that it was situated in the territory of Catania, and entirely depopulated. Avola, 16 miles from Syracuse, which formerly stood on a hill, boats of having been the Hybia major, so celebrated for its honey; but to this title so many places lay claim, that it is not easy to decide on the subject. See AVOLA, MELILLI, and PATERNO. Hybia minor, or minima, called also Heraca, was situated in the southern part of Sicily; and is placed in the Itinerary of Antonine on the route from Agrigentum to Syracuse. This is now "Calata-Girone." Hybia parva was a maritime town of Sicily, on the eastern coast. It was also denominated Gallitris, and more frequently Megara, from which the gulf, to the south of which it was situated, was called "Megaritins sinus."

HYBIE, Mount. See MELILLI.

HYBOMA. A word used by the old surgical writers for a gibbosity of the spine.

HYBRISTICA, of ἕστι, injury, in Antiquity, a foemen feall held among the Greeks, with sacrifices, and other ceremonies; at which the men attended in the apparel of women, and the women in that of men, to do honour to Venus in quality either of a god, or a goddess, or both. Or, according to the account given by others, the hybribtica was a feast celebrated at Argos, wherein the women, being drest like men, insulted their husbands, and treated them with all marks of superiority, in memory of the Argian dames having anciently defended their country with singular courage against Cleomenes and Demaratus.

Plutarch speaks of this feast in his treatise of the great actions of women. The name, he observes, signifies injury; which is well accommodated to the occasion, wherein the women flattered about in men's clothes, while the men were obliged to dangle in petticoats.

HYDAGE. See HIRAGA.

HYDARTHUS, in Surgery, signifies the disease of the joints, better known by the name of white-swelling. The term is derived from ὑδας, water, and ψαρω, a joint.

HYDASPES. See BEHU.

HYDATID, ὑδατις, in Medicine, from ὑδας, water, in the genitive case, ὑδοτις, literally a vessel containing a watery or transparent fluid, denotes certain spherical bodies, which are found occasionally in man, as well as in other animals, lodged in, or adhering to, the different viscera.

The term hydatid has been applied to two species of vesi-
cular bodies, which appear to differ very materially in their nature; one of these, which, in the human subject, is commonly found adhering to the liver, spleen, or mesentery, and appears to have no farther connexion with the body, than as it furnishes a nidus, is commonly supposed to be of an animal nature, and to posses an independent vitality: the other species, which is found attached to the kidneys, uterus, and other placenta, is considered as dependent on a mere morbid alteration of the structure of these parts. The first of these may be called the true, the second the spurious hydatid, for the sake of distinction; although at present we cannot consider the nature of either variety as satisfactorily ascertained, or the appellations as strictly correct.

1. Of the true Hydatid. The first authors, who described the hydatids accurately, and observed that they possessed the power of motion, were Phil. Jac. Hartmannus, who published his discovery in the year 1685 (see Miscell. Natur. Curios. Dec. 2. Ann. d.); and Dr. Tyfon, whose account was printed in the Philosophical Transactions for the year 1692, and who appears to have been unacquainted with Hartmann's observations. Tyfon, who described and figured the hydatid, as found in sheep, observed the neck and mouth of the animal, and saw that the mass was in motion; Hartmann further saw the whole body in motion, by putting them into warm water. Professor Pallas afterwards examined them very minutely, and finding their heads of the same structure as that of the tenias, or tape-worm, he gave them the name of tenia hydatigena. (See his Miscellanea Zoologica.) The abbé Fontaine also observed them in sheep, saw the young animals adhering to the sides of the parent bag, and also with a microscope examined the heads of them, and found them resembling those of tenias. (Opusc. Scoleri, tom. 6.) Dr. Baillie says, "there is no doubt at all, that the hydatids in the livers of sheep are animals: they have been seen to move when taken out of the liver, and put into warm water; and they retain this power of motion for a good many hours after a sheep has been killed." (Morbid Anatomy, p. 224. ed. 2d.) The late Dr. John Hunter gave the following account of some hydatids, that were found in the abdomen of a sheep, adhering to the fat about the kidneys, and to the liver, in considerable number.

"The hydatids in the sheep were exactly the same with those described by Tyfon. They consist of a mouth, neck, and oblong spherical body. The mouth had nothing of the cruciform appearance, if I may be allowed the expression, that late writers have made the characteristic mark of tenias, and which they say is to be found in all hydatids. The mouth, examined with some care with the microscope, appeared to be a simple longitudinal aperture. The neck was composed of rings, and there appeared very fine circles surrounding the body. They varied in size, from that of a cheeta to the dimensions of a turkey's egg. When put in warm water, though it must have been twelve or fourteen hours after the sheep had been killed, they moved briskly, with a kind of peristaltic motion all over the body. Each hydatid was lodged in a separate sac, which was little more than sufficient to hold it, for the neck was reflected upon the body. The sides of the sac were lubricated with a mucous fluid." See Transact. of a Society for the Improvement of Med. and Chirurg. Knowledge, vol. i. p. 50.

Hydatids are also found in the brain of sheep, in which case they produce the disease, called, in some parts of the country "the flaggers." The hydatid is lodged in the substance of the brain, in one sheep there were two hydatids, one in each hemisphere of the brain; they were of an irregular oval shape, they had no mouth; their coats had the same appearance as in the hydatids found in the abdomen; and,
and, when put in warm water, they had a strong peristaltic motion. In some there were clusters of young ones adhering to their inner coats. These were somewhat oval in their shape, and adhered by one end; but on detaching them carefully, and examining them with good magnifiers, I could never find the cruciform mouth described by some writers.

Dr. Hunter, loc. cit.

The hydatids, found in, or attached to, the liver, in the human subject, bear a strong analogy to those of sheep above described; whence it is concluded, that they are most probably also animalculae. They have never been seen to move, indeed, when taken out of the body, and put into warm water; a circumstance which may be explained by the length of time which elapses after death, before the human body is examined; during which the hydatids must have lost their living principle. There is undoubtedly some difference between the hydatids in the liver of sheep, and in that of the human subject; in simplicity of organization, the hydatid in the human liver being a simple uniform bag, and the hydatid in that of the sheep having a neck and mouth appended to the bag. But this difference, Dr. Baillie remarks, need be no considerable objection to the opinion above stated: life may be conceived to be attached to the most simple form of organization. In proof of this, hydatids have been found in the brains of sheep, resembling almost exactly those in the human liver, and which have been seen to move, and therefore are certainly known to be animalculae. (Morbid Anat. p. 255.)

In other respects, too, they bear a considerable analogy to each other.

The hydatids of the liver in man are commonly found included in a cyst, which is frequently of considerable size, and is formed of very firm materials, so as to give to the touch almost the feeling of cartilage: it is endowed with a strong contractile power, so as forcibly to protrude its contents, through any opening made into it. It consists of two coats, the outer one of which is thick and laminated, the inner a soft and pulpy lining, like coagulable lymph. A cyst may contain one hydatid, or a greater number of them; they lie loose in the cavity, swimming in a fluid; or some of them are attached to the side of the cyst.

As to the structure of the hydatid itself, they consist of a transparent, or semi-transparent bag, uniformly round and smooth, and contain a clear fluid capable of coagulation. The common colour of them is white, but they are occasionally seen of a light amber colour. The bag of the hydatid consists of two laminae, and possesses a good deal of contractile power. They are commonly unconnected with each other, or with the cyst which contains them; but sometimes they have been found to include each other in a series, like pill-boxes. On the inside of an hydatid smaller ones are sometimes found, which are commonly not larger than the heads of pins, but sometimes they are even larger in their size than a gooseberry. These are attached to the larger hydatid, either at scattered irregular distances, or so as to form small clusters; and they are also found floating loose in the liquor of the larger hydatids. Dr. Hunter observes, that when the young ones, growing in the coats of the larger ones, were examined with the microscope, they were found not to be fit in the coats like pearls, but to be covered by a thin transparent membrane, so as to lie between two layers. The most common situation of hydatids of the liver is in its substance, and included in a cyst; but they are occasionally attached to the outer surface of the liver, hanging from it, and occupying more or less of the general cavity of the abdomen.

There are many instances of hydatids, occurring in the situation last mentioned, and terminating life, in consequence of the derangement produced by the prodigious preasure on the viscera, which they occasioned. In these cases, a large swelling of the abdomen takes place, yielding a distinct sensation of fluctuation, as in acites, or abdominal dropsy, attended with emaciation of the limbs, difficulty of breathing, edema of the legs, and other symptoms of impeded functions. In one case, related by Dr. Simmons, a cyst was found after death, of immense size, filled with hydatids of various sizes, and attached to the liver, omentum, mesentery, and peritoneum. It also penetrated the diaphragm, and then, expanding again, filled almost the whole of the left cavity of the thorax, adhering to the pleura and mediastinum. The upper part of this mass communicated in several places with the lungs, which were ulcerated; so that if the patient had lived long enough, she would probably have coughed up hydatids, as one of the openings from the cyst into the lungs was large enough to admit a goose-quill. In the substance of the liver, which weighed sixteen pounds and a half, another large cyst was found. This contained ten pints of hydatids, and sixteen pints had been taken out of the abdominal cyst before the part in the thorax was examined. (See Medical Communications, vol. 1. art. 5.) A similar case is related in the Edinburgh Medical and Surgical Journal, vol. 2. p. 170, in which "an immense cyst, occupying the whole cavity of the abdomen," was found after death, containing many hydatids, many of them exceeding the largest oranges in size. In both these cases, the diffuse was supposed to be common lesions during life; and in both a fruitless attempt was made to draw off the fluid by tapping.

In the first of these instances, we have seen that a small communication actually existed between the face of the hydatid, and the cells of the lungs, although none of the hydatids had passed that way. But there are instances on record, in which the true hydatids were coughed up from the lungs. A lady of Lancaster, during an illness which continued more or less for three years, coughed up several hundreds of hydatids, most of which were burst, and of these many must have been as large as a putty's egg: thence which was not burst were only about the size of a nutmeg." (Lond. Med. Journal, vol. 6. p. 2934 for the year 1785.) This lady recovered her health; she had been considered as drophical, and having disease in the liver. Another lady, who had a tumour in the right hypochondrium, in which fluctuation was distinctly perceived, expectorated 155 hydatids in the course of four months, after which she began to amend. Med. Transact. of the Coll. of Physicians, vol. 2. art. 22.

In some cases these abdominal cysts form adhesions to, and communicate with, the alimentary canal, through which the hydatids are discharged. A lady at Windsor was treated with mercurials, under the supposition that hepatitis, and consequent suppuration in the liver, had taken place. "In about ten days the mercury began to affect her mouth, and at the same time she voided an incredible quantity of the "teneo hydatigena," or hydatides, by flux and by vomiting. Her attendants reckoned the pellet to the number of a thousand; there being as many as filled two large chamber-pots. They were from the size of a small pea, to an inch and a half in diameter, &c. An hepatic abscess afterwards opened externally, a gall-stone was discharged from it, and she ultimately recovered. (Lond. Med. Journal, vol. 10. for 1789, p. 76.) An example of fatality occasioned by a face of hydatids, situated in the porta of the liver, which, by its pressure on the veins, produced complete obstruction and jaundice,

In a few instances, small hydatids, formed in the kidneys, have been discharged by urine; as in a case related by Dr. Baillie, who observes, that "sometimes the true hydatid is formed in the kidneys, having exactly the same nature with that which grows in the liver." (Morbid Anat. p. 279.)

The hydatid, in this instance, differed much in size, from that of a small orange, to that of a pin's head: the smaller ones only were of course passed with the urine; but in consequence of the increased exertion, necessary to drive them through the urethra, the bladder had acquired a considerable thickness in its mucular coat, as in other cases of obstruction to the free passage of the urine. In a case related by Dr. John Hunter, death was occasioned by a collection of these hydatids, lodged between the bladder and rectum, filling the pelvis, and producing a fatal suppuration of urine.

Dr. Hunter puts the following query respecting the manner in which the hydatids came to be lodged in that situation.

"It has been observed," he says, "that they are most commonly found in the liver and spleen, and in the prezenz the organs in which that part of their substance is furnished with the urine; but in consequence of the contents would be spread all over the abdomen, and from their own gravity would naturally fall into the pelvis; and may they not have adhered to the neighbouring parts, and so multiplied there?"

Lastly, these hydatids are said to have been discharged from tumours in different parts of the body. See Philof. Trans. vol. 25.

Such are the situations in which the true hydatids have been observed to occur, and the modes in which they have eventually been discharged or have destroyed the patient.

Dr. Hunter remarks, that of the various cases related by writers scarcely any proved fatal, when the hydatids found an outlet. But, however defensible it might, therefore, he to procure such an outlet, where the presence of hydatids is suspected, it is obvious that, as they are generally seated in the abdomen, art can seldom if ever intercede, and the pusbeads must be left entirely to nature.

2. The porous hydatids, if that term be allowable, which are found connected with the kidneys, the placenta, the ovaries, and uterus, appear to differ greatly in their nature from the hydatids above described. They are not inclosed in firm cysts, nor exult without any attachment to each other, or the surrounding parts, nor do the latter ones contain others attached to their internal coats, or swimming in the fluid, as in the true hydatid. Their coats are also thinner, and less pulpy, and not uncommonly they are alkali as this as any membrane of the body. It is, therefore, probable that they depend on a diseased alteration of the parts in which they are seated, and are not distinct organized simple animals. (Baillie Morb. Anat. p. 278.)

The hydatid structure of the placenta is a disease not very uncommon, and usually occurs in miscarriage; for when it takes place, Mr. Home has remarked, "the natural healthy actions for the support of the feto are so much impeded, that its growth is arrested. This evidently happened in a case published, with an engraving of the placenta and fetus, by Dr. Denman: and when the patient does not early miscarry, the fetus disappears; and in all the instances where miscarriage has taken place in a more advanced stage of the disease, I believe no fetus has been found." (Mr. Home, in Trans. of a Soc. for the Improvement of Med. and Chir. Knowledge, vol. 2. p. 300.)

The hydatid, in these cases, are commonly small, from the size of a pin's head, to that of a large pea or common grape, are clustered together, and individually connected with the placenta, or with each other, by a narrow stalk or pedicle. Lieutaud has mentioned the circumstance of large masses of hydatids being found in the uterus. (Hill. Anat. Med. tom. 1. p. 335.) But it is probable, as Dr. Baillie suggests, that these were only hydatids of the placenta which had been retained there. (Loc. cit. p. 279.)

Hydatides, Ψαρρατιδες, for ψαρρα, water, in Natural History, a name given by some writers to a species of aulotis, the lineations of which resemble waves. It is by others used as a name of the enhydros.

Hydatides, in Medicine. See Hydatides.

Hydatides, in Zoology. See Tænia.

Hydatism, in Surgery, a word used by some writers to express the noise or sound made by the fluctuating humours contained in abscesses.

Hydatocholos, of ψαρρα, water, and κόλλως, col., an epithet used by the old writers on medicine for fluids more than ordinarily liquid or bilious.

Hydatoides, ψαρρακοίδες, formed of ψαρρας, ψαρρας, water, and οίδες, form, resemblance, a name some authors give to the aqueous humour of the eye, included between the cornea and uvea.

Hydatoscopa, compounded of ψαρρας, the generative of ψαρρας, water, and σκοπεω, I view, I consider, called also hydroscopy, a kind of divination, or method of foretelling future events, by means of water.

There is a natural or allowable kind of hydatoscopia: it consists in foretelling forms, tempests, hurricanes, &c. from natural signs or indications in the sea, air, clouds, &c.

Hyde, Edward, Earl of Clarendon, in Biography, was born at Dinton, in Wilshire, in February 160. He was educated in the elements of learning, under his father's roof, by the vicar of the parish, and his progress was so great that he was deemed fit for the university at the age of thirteen. He was intended for the profession of the law, and was entered very early of the Middle Temple. Here he was under the protection of his uncle, Nicholas Hyde, afterwards chief justice of the King's-bench. He had the happiness of being introduced early to a very respectable set of acquaintance, among whom were perfons of the first rank for talents and learning in the kingdom, such as lord Falkland, Selden, Kenelm Digby, Carew, Waller, Sheldon, Hales of Eton, Chillingworth, &c. of whom he has, in his memoirs, given very characteristic and entertaining sketches. To their conversation and example he has ascribed much of his own greatness, and he has strongly expressed his sense of the benefit of such society, by saying that "he never was so proud, or thought himself so good a man, as when he was the word man in company." He engaged, in a scale on the
the part of the merchants of London, which was the means of introducing him to the notice of archbishop Laud, then a commissioneer of the treasury, who became very servicable to him in his future professional advancement. His connections were the means of throwing a deal of business into his hands as a barrister, but he did not so immerse himself in legal pursuits as wholly to neglect polite literature, and by his manner of living, and the company which he kept, he seemed to affect the gentleman rather than the man of business. In the year 1640, on occasion of the Scotch rebellion, he was chosen burgess, and sat in parliament for Wootton-Basset. Almost as soon as he had taken his place in the house of commons, he brought forward a complaint of the illegal practices and oppressions of the earl marshal's court, but the speedy dissolution of the parliament prevented any proceedings upon it at that time. In the new house he sat for the borough of Saltash, and renewed, with so much effect, his attack upon the marshall's court, that he procured its suppression. He now laid aside his business at bar, and gave himself up entirely to the public concerns of the country, and being an independent gentleman, enlisted under the banners of no party, he was frequently appointed chairman of committees in matters of great importance. One of these, was that which drew up the charges against the judges for their decision in the case of ship-money. In this case he opposed the court, but at the same time shewed such an attachment to regal government, and to the established church, that he was regarded with suspicion by the heads of that party. The King was sensible of the obligations he was under to him, and took an opportunity of expressing his sense of gratitude for the services towards himself, and his regard for the national religion. Flattered, perhaps, by his sovereign's compliance, he was from this time looked upon as one of the royal party; he avows that "he had a very particular passion and devotion for the person of the king; and a most zealous esteem and reverence for the constitution of government, which he believed so equally poised, that if the least branch of the prerogative were torn off, the subject suffered by it, and he was as much troubled when the crown exceeded its just limits." When the commons' remonstrance on the state of the nation came out, Mr. Hyde, as he says, only to give vent to his own indignation, and without the least purpose of communicating it, drew up a reply, which, however, he declined to lord Digby, and at length suffered it to appear as the king's answer with the advice of his council. Soon after this he was offered the place of solicitor-general, which he declined, but agreed to be one of a private consultation on the king's affairs and their management in parliament, with lord Falkland, and sir John Colepepper. In this office he stood apart from the others, by opposing the king's attaint to the bill for depriving the bishops of their seat in the house of lords, which, however, his majesty was prevailed on to give. In April 1642, Mr. Hyde was sent for by the king to York; and repairing thither he affidted in drawing up many papers in the royal cause, and in private consultations. The parliament recalled him, but refusing to comply with their order he was exempted from pardon by a special vote. After the commencement of the civil war, Hyde was nominated to the chancellorship of the exchequer, sworn of the privy-council, and knighted. He remained with his majesty till March 1644, when he accompanied prince Charles into the West, and afterwards attended him to the island of Jersey. After the prince left the kingdom, sir Edward Hyde remained in the island two years longer, pursuing his studies in great tranquillity, and attending to the composition of a history of the transactions in which he had borne a conspicuous part. In 1648 he was ordered to attend the prince at Paris. Upon his arrival he found great differences prevailing between the queen-mother, and the duke of York. The king's court at the Hague was not in a better state of union, and he found so little good to be done by a personal attendance, that he obtained leave to retire to Antwerp, where his wife and children were, with whom he lived in a luxurious and domestic retreat, and in a style suited to his reduced circumstances. After this he removed to Breda, at the desire of the princes of Orange, the late king's eldest daughter, who proposed to take his daughter as one of her maids of honour, to which, with much hesitation, he agreed. In 1657 he was appointed to the post of lord chancellor of England, which he very unwillingly accepted, properly judging that it was ridiculous, as the office proceeded from a king without a kingdom, but it appeared that Charles, not able of himself to reject the importunities of those who were continually applying to him for contingents, grants, and revenues, willed to throw the burden upon one who had firmness enough to refuse improper requests. At the Restoration, the chancellor might be considered as the king's first and most confidential minister; and it is agreed, that he displayed great wisdom and integrity in settling the many difficult affairs which this event brought for decision. He is particularly prized for rejecting the proposal of raising a great standing revenue, which would have made the king independent of future parliaments; and for the censures with which he proceeded to disfranchise the army. He also moderated the forward zeal of the royalists, and checked their appetite for revenge. His honours naturally rose with his power, and in 1660 he was created a peer, and elected chancellor of the university of Oxford, and in the following year he was advanced to the titles of viscount Cornbury and earl of Clarendon. He also received various grants from the crown, which rendered his estate adequate to his dignity. A short time after the king's return, it was discovered that his daughter, at the princes of Orange's court, had attracted the notice of the duke of York, who, failing of successe in an attempt to obtain her favours upon easy terms, had entered into a private contract of marriage with her. Lord Clarendon was excessively indignant at this transgression, and advised the king to fend his daughter to the Tower, and bring her to condign punishment. The king, however, felt left keenly on the subject, and behaved with great clemency and propriety in the business, though the duke basely denied his marriage, and even encouraged scandalous reports against his wife. The queen-mother also expressed the utmost rage at the connection, but he was nevertheless at length acknowledged as duchess of York, and eventually gave two queens to England. This marriage was made a flap for alienating the king from his chancellor, and in 1663 the earl of Bridget exhibited various charges against him in the house of lords, which he was unable to substantiate, and which terminated greatly to the honour of the chancellor. Many other charges were brought against him; his opposition to a bill for liberty of conscience, and many of his public measures rendered him very unpopular: his admonitions of a corrupt prince alienated from him his sovereign's affection, to that, notwithstanding all his faithful services to the crown, he was, without reluctance, given up as a sacrifice to the national odium. In August 1667, he was required to resign the great seal, and was at the same time removed from all offices of public trust. He was afterwards impeached of high treason by the house of commons, but the lords refused to commit him upon their charge, and during the debates upon this head he received the king's commands to withdraw from the kingdom. Before his departure he sent an apology to the
house of peers, which was voted to be a libel, and burnt by the hands of the common hangman. A bill was now passed against him as a fugitive from justice. He landed at Cabris, but received an order from the court of France to quit their territory instantly. A fit of illness rendered this impossible, and he finally obtained permission to reside in that country. He had nearly lost his life by an attack of some English feamen, with whom he was very unaccepted; after this he proceeded to Montpellier, where he employed himself in writing a vindication of his conduct. He died at Rouen, in the month of December 1674. His body was brought to England and interred in Westminster-abbey. He left several children, of whom his eldest son succeeded him. Lord Clarendon was author of "Contemplations and Reflections on the Book of Psalms;" "A Brief View of the Errors in Hobbes' Leviathan;" "The History of the Grand Rebellion," in three volumes folio, to which was added his life, and a continuation of his history published in 1759, by the university of Oxford. This, his great work, is regarded as a valuable source of information on the events of that unhappy period. According to Mr. Hume, it is, excepting Whitelock's memorial, the most candid account of those times composed by any contemporary author. Clarendon, says the same historian, was always a friend to the liberty and constitution of his country. It is said that when he first engaged in the study of the law, his father exhorted him with great earnestness to shun the practice, too common in that profession, of laying every point in favour of prerogative, and perverting himself to a science to the oppression of liberty, and in the midst of these rational and virtuous counsels, which he reiterated, he was suddenly seized with an apoplexy, and expired in a few hours in his son's presence. As an historian, Clarendon will ever be esteemed as an entertaining writer, even independently of our curiosity to know the facts which he relates. He is more partial in appearance than in reality. He is less partial in his relation of facts than in his account of characters: he was too honest a man to falsify the former; his affections were easily capable, unknown to himself, of disguising the latter. "An air of probity and goodness," says Hume, "runs through the whole work, as these qualities did in reality embellish the whole life of the author." See Hume's Hist. vol. vii. octavo. Biog. Brit.

HYDE.

HYDE, W., a profound Oriental scholar, who flourished in the seventeenth century, was born at Billingbear, near Bridgenorth, in Shropshire, in the year 1636. He received the elements of a learned education under his father's instructions, and at the age of sixteen he was entered of King's college, Cambridge. In the course of two years he was sent to London to the learned Walton, afterwards bishop of Chester, as a person very capable of affording him in preparing for publication the grand polyglot bible, on which he was then engaged. Mr. Hyde rendered this undertaking the most essential services: he transferred the Persian Pentateuch out of the Hebrew characters, in which it was first printed, at Constantinople, into the proper Persian characters. Of this Pentateuch, Mr. Hyde added a Latin translation; and he further added in correcting different parts of Walton's work, in the Arabic, Syriac, and Samaritan languages. In 1658 Mr. Hyde went to Oxford, and was admitted of the Queen's college, and soon afterwards appointed Hebrew reader in that society. Soon after the restoration of king Charles II. Mr. Hyde was made under-keeper of the Bodleian library, which furnished him with ample opportunities of prosecuting his favourite studies with singular advantage, and in 1665 he was elected to the office of head-keeper. In the same year he published "Versus Latinae Lingua Persica, et Commentaria in Observationes Ulug. Begi de Tabulis Longitudinis, et Latitudinis Stellarum fixarum." About the time when this work was first published, Mr. Hyde became acquainted with the great Mr. Bowles, to whom he communicated several remarkable passages relating to chemistry, physics, and natural history, which he had collected from Oriental writers. In 1666 he was promoted to a prebend in the cathedral church of Salisbury, and in the following year he published "Quatuor Evangelia, et Acta Apostolorum, Lingua Malalæ, Charactaribus Europæis," printed at the expense of Mr. Bowles. In 1674, he gave the world "Catalogus impressorum Librorum Bibliothecæ Bodleianæ in Academia Oxon;" and in 1678 he was made archdeacon of Gloucester. Two years after this he was admitted to the degree of doctor of divinity, and from this period he was frequently giving additional proofs of his unremitting study, and singular skill in all kinds of Oriental learning. An account of his several learned works will be found in the Biographia Britannica, and also in a more abbreviated form in the General Biography. In 1697, Dr. Hyde was appointed regius professor of Hebrew, and canon of Christ-church. Shortly after this he published "the Religion of the ancient Persians." Dr. Hyde's profound skill in Oriental literature, and desire to promote it, would have led him to publish many more learned works than he did, could he have obtained encouragement from the public. The want of this obliged him to decline running the risk of printing any thing more, and on a similar account the writings which he left behind him were suffered to be neglected, till it was too late to recover them, though the loss has ever since been regretted by the learned, and those who knew how to estimate their value. In 1701 Dr. Hyde resigned the office of head-keeper of the Bodleian library, on account of his great age and infirmities. During the reigns of Charles II., James II., and William III. he had occupied the post of interpreter and secretary in the Oriental languages; and in the course of his employment, had made himself most intimately acquainted with the policy, ceremonies, and customs of the Oriental nations. Dr. Hyde died in the year 1702, at his apartments in Christ-church, in the sixty-seventh year of his age. We shall transcribe the character of this great man as given by Granger: "Dr. Thomas Hyde," says he, "is a great character, but is much less known than he deserves to be, because the studies in which he was occupied are but little cultivated. Those that are acquainted with the Oriental languages, are astonished at the progress which was made in them by one man, though aided by the power of genius, supported and strengthened by incessant industry. There never was an Englishman, in his situation of life, who made so great a progress in the Chaldee, Bochart, Pococke, and Hyde, are allowed to be the greatest Orientalists that any age or nation have produced. I am informed that Dr. Hyde's mind had been so much engrossed by his beloved studies, that he was but ill qualified to appear to any advantage in common conversation." Dr. Gregory Sharp, master of the Temple, collected and republished some of his pieces which were formerly printed. These made their appearance in two volumes quarto, under the title of "Syntagma Dissertationum et Opuscula." Anthony Wood has preferred a catalogue of MSS. which Dr. Hyde had either completed, or in part prepared for the press. Biog. Brit.

HYDE, in Geography, a maritime county of America, in Newbern district, North Carolina, bounded E. by the ocean, W. by Beaufort county, N. by Tyrrell, and S. by Carteret, it contains 4783 inhabitants, of whom 1886 are blacks.

HYDE OF LAND. See Hyde.

HYDEGILL. See Hydegill.
HYDEPARK, in Geography, a township of America, in Orleans county, in Vermont; containing 110 inhabitants. HYDER ALLY, in Biography, was a soldier of fortune in the East, and the son of a person who served in quality of a “killer,” or governor of a small fortres, to one of the kings of Myfore. He is said to have acquired the rudiments of war in the French camps; and in the year 1755, distinguished himself as their aentst to the plains of Trichinopoly. About 10 years afterwards, being then at the head of the Myfore army, he destronhed his sovereign, and governed under the title of regent. Soon after, he extended his dominion on every side, the Carnatic excepted: the fine province of Bednore (or Biddanore) and the Patau nabobs of Cuddapah, Canou, &c. besides some Mahrauta provinces towards the river Kistnah, and the country of the Nairs, and other small states on the Malabar coast, were added to his original posessions; until at last he was at the head of a State, in extent equal to Great Britain, and producing a grofs revenue of four millions sterling. The civil broils and revolutions in the western Mahrauta part, particularly in latter times, allowed Hyder to aggrandize himself at his eonce, being not without receiving some fave checks from foreign powers. Before he had arrived at the height of his power, the war between him and the English broke out in 1767; yet, nevertheless, his power alarmed his neighbours, and a revolution was formed for attacking him. The Mahrautas under Maderow entered Hyder’s country on the side towards Vishapour; and the Nizam, joined by a detachment of British troops, moved from Hydrabad towards the frontier of Myfor, soon after. Hyder first contrived to buy off the Mahrautas with a large sum of money, and the restitution of some of the places which he had taken from them. He next negociated with the Nizam, and succeeded not only in detaching him from the English, but in drawing him over to his party: so that the English detachment was compelled by necessity to retire to the Carnatic; on the frontiers of which their great army was now assembing. The superiority of the Nizam in the Carnatic had been always nominal; however, Hyder who now meditated the conquest of it, was glad to obtain from the Nizam a grant, or “fumud,” for the nabobship of it; and from this time, at least, he considered Mahomed Ally as his rival. In the days of this late mention’d prince’s detreifs, when he poffessed only the small part of the Carnatic, he had engaged to cede the fortres of Trichinopoly, an important port in the southern division of it, to the king of Myfor, for the assistance then afforded him; but this engagement never being performed, Hyder adopted the claims and resentments of the princes of whom he had taken possession; and never lost sight of his title to Trichinopoly. In the war that immediately ensued, a strong detachment of the British army seized on Hyder’s province of Coimbattore, a fertile district on the south of Myfor, and commanding a ready path to Hyder’s capital, Seringapatam. During the years 1757, 1758, and part of 1759, the war was continued with various succes. (See HINDOSTAN.) In 1771, Hyder suffered a total defeat from the Mahrauta army within a few miles of his capital, into which he escaped with great difficulty, and after having sustained a great loss. Here, as his enemies had neither skill nor the ordinary requisites for a siege, he remained un-opposed, and patiently waiting the retreat of his enemies after they had defeated the country. Some subsequent years of peace were very much improved both his army and revenue; and the distractions that subsisted among the Mahrautas afforded him an opportunity of extending his territories at their expense. Hyder’s projects of ambition were counteracted by two unsuccessful campaigns, in which he combatted with the British troops under Sir Lyce Coote; so that

in October 1782, he was reduced to the necessity of earnestly wishing for peace. Soon after Hyder died, and was succeeded by his son Tipoo. (See HINDOSTAN.) Major Rennell, at the close of the short abstract which he has given in the introduction to his “Memoir” of the history of Hyder, subjoins the following outline of his character, which, as he conceives, has been little understood. His military fame, the improvement of discipline; attention to merit of every kind; conciliation of the different tribes that ferved under his banners; contempt of state and ceremony, except what naturally arose from the dignity of his character, and his consequent economy in personal expenses (the different habits of which form the chief distinction of what is called character among ordinary princes), together with his minute attention to matters of finance, and the regular payment of his army:—all these together raised Hyder as far above the princes of Hindostan, as the great qualities of the late Prussian monarch raised him above the generality of European princes; and hence I have ever considered Hyder as the FREDERIC of the East. Cruelty was the vice of Hyder; but we are to consider that Hyder’s ideas of mercy were regulated by an Asiatic standard; and it is not improbable that he might have erred his own character for moderation and clemency, as far above thole of Tamerlane, Nadir Shah, and Abdallah, as he rated his discipline above theirs. HYDERGUNGE, in Geography, a town of Hindostan, in Odce; 21 miles W.N.W. of Fyzabad. HYDERGUR, a town of Hindostan, in Bednere; nine miles S.W. of Bednore. HYDNPHELUM, or HYDNNPHYLLON, in Botany, a name given by the ancient Greeks to a plant which they tell us grew on those places where the tubera or truffles lay underneath. HYDNORA. See APHYTENIA. HYDNUM, an ancient name adopted by Linnaeus, but misapplied, as the Thes’s of Dioscorides, Thes’s of Theophrastus, so called from thse, to foul, is the Truffle or Tuber.—Perfoon Syn. Fung. 554. Linn. Gen. 568. Syl. Veg. ed. 14 978. Schreb. 269. Mart. Mill. Dict. v. 2. (Erinaceus; Dill. Gell. 188. Mich. t. 72.) Clas and order, Cryptogania Fungi. Nat. Ord. Fungi.

Eff. Ch. Cap turbinato; smooth above; echinat beneath with awl-shaped fibrres. Obf. Thse awl-shaped bodies which Linnaeus compares to the prickles of a hedge-hog, are soft, solid, conical, or cylindrical subistance, emitting feeds from every part of their surface. Bulliard. This is a very extensive genus of Fungi, Perfoon in his Synops having described 26 species, most of which have been figured either by Sowerby, Bulliard, Jaquin, or Schrad.—Linnaeus was acquainted with only 6 species of HYDNUM. These plants are chiefly found in mossy situations upon the decayed trunks of trees. It will be sufficient to enumerate a few of the most striking species. —H. imbri-atum, Sowerb. Fung. t. 73, was communicated from lord Ongley’s plantations in Bednere. Its colour is a duffy yellow, having a reddish brown border.—H. repandum, t. 175, is found plentifully in Peckham and Hornsey woods, during autumn. This is of a fine reddish buff colour, and very brittle in substance.—H. Davisi, t. 15, is a small yellow or brown fungus; when fresh of a pure white, more rare than beautiful, very similar in texture to Botulis verticic-ter, and was first discribed in Anglesea by the Rev. H. Davies.—H. sabulametum, t. 112, of a delicate white colour, was sent from Bedfordshire by the Rev. Dr. Ab-bot.—H. aurispafum, Barks최, coralloides, membranaceum, and ramifum, is conspicuous species are also figured by the same author. H. aurispalum, beautifully displayed in
in Curt. Lond. fac. 3. t. 68, is of a brownish colour and grows upon the cones of fir-trees. Curtis mentions it as an excellent example of this genus for the instruction of a young botanist.

Moll. Hydra are furnished with items, but not all. H. paratiticus is the only Linnæan species that is itemes.

HYDRA, in Afronm, a southern constellation, consisting of a number of stars, imagined to represent a water serpent. The stars in Hydra, in Ptolemy’s Catalogue, are twenty-seven; in Tycho’s, nineteen; in Hevelius’s, thirty-one; and in the British Catalogue, fifty. See Constellation.

Hydra, in Geography, a small island in the Grecian Archipelago, about 10 miles long, and two broad. N lat. 37° 20’. E long. 23° 30’.—Also, a town of Africa, in the kingdom of Tunsia, on the frontiers of Algiers, situated in a narrow valley, near a running stream and the site of extensive ruins; 90 miles E.S.E. of Conflantina.

Hydra of Lerna, in Mythology, a terrible monster, born of Typhon and Echidne, according to Hesiod; which was destroyed by Hercules. The poets represent it sometimes as a serpent, branched out into several other serpents, and sometimes with a human head, bearing serpents instead of hair; and they add, that when one of the serpents heads were cut off, a double head sprouted in its place.

This Hydra with many heads is said to have been only a multitude of serpents, which infested the marshes of Lerna, near Mycenae, and which seemed to multiply as they were destroyed. Hercules, with the aid of his companions, cleared the country of them, by burning the reeds in which they lodged. See Hercules.

Hydra, in Zoology, a generic name of the polyopes. See Polyope.

Hydra is also a synonymous name given by different authors to various animals, as, for instance, by Linnæus to Tana globula, by Bohadich to Holothuria tubulosa, and again by Linnæus with the specific term of glomerata to Corallina pellucilis.

HYDRABAD, or Bagnagar, in Geography, a city of Hindoostan, and capital of a province, to which it gives name, now called Gokonda. (which lee,) is the present capital of the Nizams of the Deccan; who, since the dismemberment of their empire, have left Aurungabad, the ancient capital; which is not only in a corner of their dominions, but in that corner which lies near their hereditary enemy, the Poonah Mahtrattas, and which is also the least defensible. Hydрабad was formerly only a palace of pleasure, and celebrated for the beauty of its gardens and delightful views of its situation; but in the 16th century, the king of that period was induced, by the persuasion of one of his wives, to build a city, after whom called it Bagnagar, or the gardens of Nargar. It is of large extent, surrounded with walls, and defended with towers; and is supposed to contain upwards of 100,000 inhabitants. The suburbs are extensive, and inhabited by merchants and tradesmen; 352 miles N.N.W. of Madras. N. lat. 17° 12’. E long. 78° 51’.

Hydрабad is also the name of a fortress of Hindoostan, situated on the Indus, not far above the head of the Delta, and in the vicinity of Nasafpor; the usual place of residence of the prince of Sindy.

HYDRACHNA, in Entomology, a genus of the apterous order, establishef by Muller, the character of which, as reduced by Gmelin to the arrangement of the "Syllerna Nature," confits in the head, thorax, and abdomen being united; the feelers jointed and two in number; the eyes either two, four, or six, and the legs eight.

Till within the space of the last few years, almost every author, not excepting Linnæus and Geoffroy, have confounded the hydrachna with the acarus tribe; while, from their similarity of aspect, the globular form of the body, and the length of their feet, these insects were considered by general observers as no other than a race of spiders, to which the significant appellation of aquatic was most commonly annexed, because they inhabit watery places, and thus appear from their habits, though not in form, to constitute a distinct family from the true or terrestrial spiders. Both Rösef and Deguer have entered with a peculiar share of minuteness into the history of these animals; and it is more than probable the observations of these naturalists might furnish many very useful suggestions to the ingenious Müller, whose monographia on this curious race appeared in 1781. This conjecture is doubtles correct, but nevertheless the tract, or rather history, published under the title last mentioned, contains a fund of new and valuable information; it elucidates in a very comprehensive manner their internal as well as external conformation, and besides, condenses into one point of view a series of no less than fifty distinct species, the far greater part of which was totally unknown to any of his predecessors. These species are divided into three families, according to the number of eyes in each, which are either two, four, or six; those of the first division have the body of the male terminated in a kind of tail or elongated process.

After the publication of this useful work the genus hydrachna, as proposed by the author with some slight amendments or deviations, was embraced by the generality of naturalists, and still continues to be approved by the best authorities. Fabricius is indeed an exception; that excellent entomologist perhaps, without mature consideration, and certainly without affording us any reasonable grounds for believing he was so well acquainted with this tribe of creatures as Müller, rejects the genus altogether, and refers the few species he describes, which really belong to that tribe, to his genus Trombidium. Gmelin, on the contrary, differs from Fabricius in this respect, and adopts the genus together with its numerous species as described by Müller. The most material, and in our opinion the most able deviation from Müller, hitherto proposed, is that submitted by Latreille; this very affidious and intelligent naturalist agrees with Müller in considering the hydrachna as a distinct natural family, but instead of allowing them to remain under the insect tribe in conformity with preceding writers, he referred them in the first instance to the crustaceans, and since that time to the Arachnidae, in which latter they constitute his family Hydrachnelae. The Hydrachnelae of this writer are divided into three different genera, Callias, hydrachna, and limnochore; the frill of which is furnished with mandibles, as we find exemplified in the Fabrician Trombidium extendens. That to which the name of hydrachna is retained has no mandibles, and is furnished with a projecting fipon in the form of a beak, the feelers are advanced, and have a moveable appendice, and the body is of a globular figure: Trombidium geographicum of Fabricius is an illusirative example of this genus. The limnochore genus has no mandible; a fipon not at all, or very little projecting; feelers curved, without appendgments, and the body deprent; the Linnæan Acarus aquaticus is of this genus.

The hydrachna, as we have before said, are vulgarly called water spiders; they are all of the aquatic kind, resting among plants that grow in the water, or in the banks of ditches, and other situations contiguous to their favourite element. When in the water they swim with great facility by means of their feet, which in most species, when attentively examined, appear ciliated, and admirably adapted for that purpose;
their skin is thick, and their body covered more or less with
down, hair, or spines. The females are larger than the
males, and often different in colour. In general their colours
are remarkably bright, and possess a peculiar degree of brilli-
ance when seen in the water; the prevailing hues red or green,
and silvery. They are excessively abundant in spring, and
some of the species are almost constantly seen at that
season of the year, on the surface of flagrant pools of
water; they couple in the midst of summer, and de-
posit their eggs in clusters, chiefly among the weeds; these
eggs are of a red colour, and at first spherical, but afterwards
change to a semilunar form; the larvae are furnished with six
feet, and have a proboسف of very singular structure. The
hydramine prey upon the larvae of the tipulæ and monoculli,
and the juices of decayed vegetables, and are themselves the
food of fishes, of many insects that reside in the water while
in the state of larva, of polypyes, and many of the larger kinds
of aquatic worms.

Species.

* Sestum. Eyes two; Body tailed.

Globator. Globular; eyes red. Müll.
Abundant in ditches, and other flagrant waters; the male
greenish spotted; female bluish, without spots, and twice
the size of the male.

Tabular. Globular, yellowish, with spotted disk; tail
cylindrical and equal. Müll.
Inhabits flagrant waters, and in some respects resembles
the former.

Buccinator. Obovate, red, behind black; tail cylin-
drical, yellow and narrow at the base. Müll. Fromellum
caudatum, Fabr. Acarus caudatus, Degger.
Lives in banks, the body beneath black; eyes reddish;
legs black.

Cuspidator. Brown, truncated before, and macronated
behind; tail depressed and bidentated. Müll.
Body depressed, and broader on the anterior part; behind
narrow, and armed with an erect triangular spine; eyes black;
legs pale. Lives in fish-ponds.

Pustulator. Gibbus, red; tail depressed, with obtuse,
angles. Müll.
Body smooth, and generally covered with animalculles of
the vorticella tribe. In gravelly streams.

Alator. Rounded, grey, with a white disk; tail de-
pressed, and armed with three teeth. Müll. Acarus globo-
Found in fish-ponds.

Maculator. Rounded, cincereus, spotted, and mac-
ronated behind; tail depressed, and armed with three teeth.
Müll.
In ditches; breast whitish; legs green.

Thriceuspidator. Red, with a triple gibbosity on the
back; tail depressed, and three-toothed. Müll.
The body is somewhat reticulated; breast blackish; feelers
and legs whitish. Found in pools.

Emarginator. Red, with the back gibbus; tail de-
pressed, and marginate. Müll.
Feelers and legs greenish. Occurs in boggy situations.

Sinitator. Grey; the back yellowish on the fore parts
and trisetulated behind; tail depressed and squatted. Müll.
Body reticulated; feelers and legs white. Found in flag-
nant waters.

Integrato. Green and without spots; tail depressed
and entire. Müll.
Found in ditches; the body roundish oval, depressed, and
contracted behind; breast yellowish; legs hyaline.

Papillator. Rounded, purple with an encrustation
each side the tail; legs black.
Inhabits wet meadows.

** Sestum. Eyes two; Body marked with a Fork.

Grossipes. Nearly square, white, with three spots and
a rufous fork; anterior legs thick.
Body pellucid and glabrous; legs twice as long as the
body. Inhabits ditches.

Crasipes. Obovate; black, the disk black with a red-
dish fork; tail papillous; anterior legs thick. Müll.
Found in fish ponds and dykes; legs three or four times
the length of the body; pellucid; breast whitish; eyes black.

Grossipes. Nearly square, white, with three spots and
a rufous fork; anterior legs thick. Müll. Geoffr.
Inhabits fish-ponds; body glabrous; legs twice the length
of the body.

Clavicornis. Obovate, rufous with a yellow fork;
feelers clefted; legs pale. Müll.
Found in ponds; the eyes black; legs and feelers white.

Spinipes. Oval, greenish yellow, with eight dots and a
rufous fork; legs spinous. Müll.
Inhabits pools. The body polished, with the eyes, breast,
and legs; spots on the back black.

Longicornis. Nearly square, white with five brown
spots and a rufous fork; feelers long. Müll.
Frequent rivulets; pellucid; eyes black; breast pale
yellow.

Vernalis. Oval, greenish with a deeper disk, and ru-
fous fork. Müll.
Inhabits overflowed meadows; and has the appearance of
a grey dot; the legs white.

Luxipes. Oval, white, spotted, with a clear white fork;
fourth joint of the posterior legs lunated. Müll.
Found in ditches, the body pellucid, with large eyes,
and the legs and feelers pale.

Trifurcalis. Oval, whitish, with a brown back and
triple silver fork. Müll.
Frequent wet meadows; the feelers ending in a claw,
and the legs pale greenish white; eyes black; abdomen
broad, sometimes brown with a white line.

Oribcularis. Depressed, orbicular, pale yellow with
black spots on the disk and a rufous fork. Müll.
Eyes black; legs white. This species occurs in rivers.

Stellaries. Globular, blue, with a cineraceous back and
fleaded fork. Müll. Subzer, &c.
In the banks of rivulets; the body of this kind is reticu-
lated; and the legs somewhat longer than the body.

Ovalis. Ovate, compressed, greenish and flattish above,
carinated and yellow brown beneath; feelers placed beneath.
Müll.
Found in overflowed meadows. Eyes and legs black.

Elliptica. Rounded, blue with fulvous spots and dots.
Müll. Acarus maculatus aquaticus, Degger.
A scarce species found in rivers; eyes black; legs white,
breast, tail, and posterior margin yellowish.

Oribulata. Depressed, orbicular, violet, with a white
spot and circle. Müll.

Breast fulvous with the tip green; feelers and thighs whit-
ish; eyes black. Inhabits muddy ditches.

Lugubris. Globular, brownish, with black flecks; legs
white. Müll.
In boggy places; eyes black; feelers green.

Truncatella. Grey, oblong, truncated behind, with
dusky dots and lines. Müll.
Inhabits marshes; eyes black, feelers white.
HYD

*** Section. Eyes two. Body glabrous.

DESPICENS. Rounded, red, with numerous spots; eyes placed beneath. Müll. Aranact aquatiae, Frisch.

Found in ditches; body slightly depressed, thick and wrinkled; eyes blackish; legs pale yellow.

The largest and most beautiful of its genus; eyes, feelers, and last joint of its legs red. Inhabits ditches.

Inhabits stagnant waters; lines on the body beneath, with the eyes and legs black.

Extends. Rounded, red; hind legs contracted. Müll.

In ditches; body convex, and shining.

Found in overflowed meadows; eyes red; feelers downy.

Found in marshes; a supposed variety has the feelers longer.

Ovata. Obvate, grey-brown, with a triangular fulvous spot; legs pale black. Müll.

Another analogous kind, an apparent variety of ovata, has the body marked with a fulvous cross, and the legs with the eyes and feelers black. Both are found in ditches.

Lunaris. Oval, rufous, with a black lunate spot on the back. Müll.

Inhabitants fish-ponds; the eyes are black, and the legs grey.

Liliacea. Obovate and whitish, the disk lily-white, with a black spot each side. Müll.

The feelers, legs, and breast are pale, the latter spotted with black. This kind inhabits fens.

Turris. Oval, yellowish, with lateral black spots, and red in the middle; hind flanks lamellated. Müll.

Found in ditches, the eyes black, and legs white.

Strigata. Oblong, yellowish-green, the fore part depressed, with two blackish streaks united behind. Müll.

Near the banks of rivers; the eyes are black; feelers and legs white.

Oseolata. Rounded, reddish-brown, with a double obdolute streak behind the eyes. Müll.

Frequents the waters of woody situation; the eyes are black; feelers pellucid; and the legs pale-brownish.

Noleta. Red, truncated before, and spotted each side; posterior legs knotty. Müll.

Occurs in ditches; the eyes are black; feelers annulared; legs yellowish and longer than the body.

Complanata. Green, depressed, and emarginate before, with a white band in the middle. Müll.

The body elliptic; eyes black; legs and feelers pellucid.

Musculus. Green, oval, compressed, grooved above, beneath carinated. Müll.

Varies in colour; the eyes are black, feelers white, and pellucid. Found in marshes.

Latipes. Oval, yellowish, and spotted each side; fourth joint of the posterior legs dilated. Müll.

In marshes; the legs pale-blueish, with the tip brown.

Vericolor. Nearly square, with whitish, blue, and brown spots. Müll.

Found in wet meadows; the body white, beneath brown, with a yellow margin; feelers and legs pellucid, white.

HYD

*** Section. Eyes four.

Calcarea. Rounded, brown, with a clear white disk. Inhabits marshy woods; the eyes are black; feelers pointed, and the legs pale and pellucid.

Fuscata. Ovate, reddish-brown, with a darker disk, and pale rufous fork. Müll.

The body is convex, and spotted on the back; eyes black; legs and feelers white and pellucid. Found in muddy ditches.

Undulata. Oval, pale-yellow, with flaccid black streaks. Müll.

In marshes. The body sub-globular, pellucid, with black eyes.

Maculata. Oval, red, with black spots on the back. Müll.

Eyes black; legs and feelers pale-yellow, and pellucid.

*** Section. Eyes fix.

Undata. Rounded, red, with numerous dark spots. Müll.

Inhabitants marshy woods; the body glabrous, sub-depressed with ten darker spots above, beneath blackish; eyes black; feelers yellowish at the tip; legs yellow.

Hydragogues, Hydrogogata, &c., &c., from Latin words, water, and στήγα, στήγα, in Medicina, as an appellation given to those purgatives which produce copious watery fluids.

The most acid and drastic purgative drugs are those to which the epithet of hydragogus is particularly applicable; not as the ancients conceived, because they have a particular attraction for the watery part of the circulating fluids; but because, by their powerfully stimulant operation on the mouths of the exhalent arteries, which open every where along the inner surface of the intestinal canal, they occasion those vessels to pour out their fluids in great abundance, and thus render the fluids thin and watery. Of the more active hydragogues in modern use are the elaterum, febrifuge, camomile, &c.; salicylic, colchicum, andsome other substances of a less acid quality, when administered in large doses, likewise excite a copious excretion of watery fluids from the intestines. Some caution is requisite in the administration of these active cathartics, especially in habits originally delicate or weakened by disease, or in those who are unusually irritable. Painings, convulsions, and even death have been the consequence of excessive purging; and these results appear to have been not very rare among the ancients, who were obliged to have recourse to such medicines as white hellebore, when a considerable catharsis was necessary. "Convulsio poth hemelorum lethali, " is an aphorism more than once expressed by Hippocrates. A hypercathartica, with bloody stools, is a more common consequence of hydragogue purging in modern times. See Hypercathartica.

Drastic hydragogues are seldom indicated, except in dropy especially of the belly, in which a copious watery discharge from the intestines occasionally effects a cure of the disease; or in cases of paralytic torpor extending to the bowels, in hemiplegia; or in the painter's cholera, after the spasm has been relaxed by opiates. In enteritis, or inflammation of the bowels, hydragogues should be cautiously used, notwithstanding the confirmed state of the canal; for since the condition arises from the inflammatory condition of the intestines, every acrid stimulant applied to them must inevitably augment, rather than alleviate the disease. See Cathartic.

Hydrangea, in Botany, from ᾳδραγος, water, and άγωγα, a vessel, so named by Gronovius, in allusion to the pitcher-like shape of the feed-vessel. Linn. Gen. 222. Schreb.
HYD

Gen. Ch. Cal. Perianth of one leaf, superior, five-toothed, permanent, fmal. Cor. Petals five, equal, roundish, larger than the calyx. Stam. Filaments 10, longer than the corolla, but sometimes alternately longer and shorter themselves; anthers roundish, twin. Pjft. German roundish, inferior; styles two, short, dilant; filgas obtuse, permanent, Peric. Capsule roundish, twin, the double style forming two beaks to it, angulated with many nerves, crowned by the calyx, two-celled by a transverse partition, opening by a hole between the horns. Seeds numerous, angulated, pointed, very smal.

Eff. Ch. Calyx superior, five-toothed. Corolla of five petals. Capule of two cells and two beaks, containing many seeds.

1. H. hortenfa. Chinese Guider-rofe. Willd. Sp. Pl. No. 2. Sm. t. 1. Pict. t. 12. "Leaves elliptical, serrated, very fmoother. Stamens all of an equal length."—This thorn is a native of the Eaft, and is usually cultivated in the gardens of China and Japan. From whence it was introduced into Kew gardens by Sir Joseph Banks in 1790.—Root fibrous, much branched, whitish. Stam. erect, shrubby, having a smooth brown bark. Branches opposite, leafy, green, speckled with dark purple spots, flowering at the top. Leaves opposite, spreading and curved backwards, bright green, veiny. Clifters of flowers terminal, of a beautiful rofe-colour, inordinate, green when young as well as in decay. Calyx only seen by us in a luxuriant state of deformity, very large, composed of four (rarely three or five) spreading unequal, obovate leaves, which are entire, smooth, rofe-coloured, slightly ribbed and permanent. Petals generally four, nearly equal, small, obovate, concave, of the colour of the calyx, fading. Filaments awl-shaped, red; anthers greyish, with yellow pollen. Styles purple.

This plant, which is nearly allied to Viburnum and Sambucus, is much esteemed for its very elegant flowers and easy culture. We have fected H. hortenfa for a specimen of the genus, as it is the most beautiful species, out of the four defcribed by Willdenow. The others, H. arborescens, radiata, and squerifolia, are of American origin, tolerably hardy in the gardens of Europe.

Hydrangea, in Gardening, comprehends plants of the shrubby and flowering perennial kinds; of which the species cultivated here are; the shrubby hydrangea (H. arborescens); and the garden hydrangea, or Chinese guider rofe (H. hortenfa.).

The latter of these farts is held in high effimation on account of the number of elegant flowers which it displays.

Method of Culture.—The firt of thefe plants is increased by fipping off or parting the roots in the early autumn, and planting them out where the plants are to grow. It succeeds beat on a moist soil, and requires no trouble but being kept free from weeds, by digging the ground about it in the winter. When the flims are defeured in fvere froths, new ones are put forth in the enfuing spring feafon.

And the second fort is easily increased by planting cuttings of the young fhoots, in pots of rich loamy earth in the spring, plunging them in a moderate hot-bed. When they have firken good root, they should be removed, with balls of earth about their roots, into separate pots, and be placed in the green-houfe or under other fimilar protection.

But though this plant is capable of flanding the open air in mild winters, in warm dry situations, it does not flower so well as in the green-houfe. Superfluous plants should therefore only be employed in this way as they may frequently be defroyed.

These are ornamental plants; the former in fronts of clumps and borders, and the latter among green-houfe collections and other potted plants, where it produces a fine appearance during the flowering feafon.

HYDRAOTES, in Ancient Geography. See Rauw.

HYDARGYROSIS, a term used by the chirurgical writers to express the anointing of the body with a mercurial unction, in order to the raising a falivation.

HYDARGYRUM, Υδραγύρος, a name given to mercury, or quickfiver.

The word is formed of ωδρα, aqwi, water, and τςργς, argęns, sum., fiver; q d water of fiver, on account of its resembling liquid or melted fiver. For an account of mercury and its different preparations, see Mercury.

HYDRASPIS, water fide, or water buckler, a machine of wood, invented by John Christopher Wagenfeil, a German, by the help of which a perfon may walk on the water, without fear of finking. It encompafles the break, ferving the office of the cheli in water-fowl, and is furnished with apertures for receiving a quantity of food, or for preferring money, writings, or other valuable things, in case of an inundation. The person who ufes it is provided with paddles for the feet, confisting of moveable flaps of very thick leather, which open and flut, and are falleden to a wooden sole, on which the foot reffes, by an iron pin fifting through their hinges. They are falleden to the feet by straps or thongs. The inventor of this machine made trial of it in a whirlpool of the Danube, where he moved about in the current without danger. He propofes, that this machine fould be ufed in a shipwreck, in efcapeing the danger of sudden inundation in paffing a river, for the fervice of war, and hunting and taking water-fowl, &c. Act. Erud. ann. 1691, p. 40.

1. H. canadenfa. Canadian Yellow-root. Linn. Sp. Pl. 784. (Warneria canadenfa; Mill. Dict. 190. t. 285. Hydrophyllum verum canadenum; Linn. Sp. Pl. ed. 1. 145.) This bog plant is a native of Canada, and flowers in May or June. It was firft cultivated by Mr. P. Miller in 1759.—Root of a deep yellow colour within, whence its English name, throwing out fibres in the spring. Stam. about nine inches high, at firft light green, but afterwards tinged with
HYDRAULICS, that part of statics which considers the motion of fluids, and particularly water; with the application of it in artificial water-works. Hydraulics, as distinguished from hydrodynamics, is that science which treats of certain machines or engines, in which fluids are principally concerned.

The word is derived from the Greek, ὥδρα, water; and αὐτής, of her own; and is allied to Podophyllum. It is remarked by Linnaeus, in his herbarium, that the flowers of this plant were unknown to his pupil Kalm. We are not aware that it has been figured by any author except Miller, as quoted above.

HYDRAULICS, that part of statics which considers the motion of fluids, and particularly water; with the application of it in artificial water-works. Hydraulics, as distinguished from hydrodynamics, is that science which treats of certain machines or engines, in which fluids are principally concerned.

The word is derived from the Greek, ὥδρα, water; and αὐτής, of her own; and is allied to Podophyllum. It is remarked by Linnaeus, in his herbarium, that the flowers of this plant were unknown to his pupil Kalm. We are not aware that it has been figured by any author except Miller, as quoted above.

HYDRAULICON, or, the Ancient Music, an organ blown by the fall of water. From the description of this instrument by Vitruvius, cap. xii. it seems as if the water which forced the air into the pipes was pumped by men. Indeed, it has been much disputed whether it was played with fingers, by means of levers or keys; and yet the description of it by Claudian seems such a one as would suit a modern organ, only blown by water instead of bellows.

"Vox magni levi detrudes murmura tecta
Innumeras voces fegetis moderator cæna
Interon errant digitus, penitusque trabali
Vece laborantes in carrina concitate undas."

In Athenæus, lib. iv. p. 174, there is a history and description of this instrument. He tells us that it was invented in the time of the second Ptolemy Euergetes, by Cleobius, a native of Alexandria, and by profession a barber; or rather, that it was improved by him, for Plato furnished the first idea of the hydraulic organ, by inventing a night-clock, which was a deepdyke, or water-clock, that played upon flutes the hours of the night at a time when they could not be seen on the index.

The anecdote in Athenæus concerning the mechanical amusements of the great ideal philosopher, is curious. What a coincidence in the divine Plato to stoop to the invention of any thing useful! This musical clock must have been wholly played by mechanism. But neither the description of the hydraulic organ in Vitruvius, nor the conjectures of his innumerable commentators, have put it in the power of the moderns either to imitate, or perfectly to conceive the manner of its construction; and it still remains a doubt whether it was ever worthy of the praise which poets have bestowed upon it, or superior to the wretched remains of the invention still to be seen in the gardens of the vineyards, near the city of Athens.

The pneumatic organ, or instrument blown by bellows, and furnished with keys, such as are in present use, though perhaps a descendant from the hydraulicon, will have a distinct article, where its invention will be described, and its improvements traced, among those of modern instruments.
HYDRAULO-PNEUMATICAL, a compound term, applied by some authors to such engines as raise water by means of the spring of the air. See Air, Water, and Engine.

Mr. Boyle mentions a very pretty fountain, which he calls hydraulico-pneumatic; made by the spring of the air pressing up water in a pipe upon the air's being exhausted out of a receiver, and thus the weight of the atmosphere taken off. See Fountain.

HYDREA, in Ancient Geography, an island of the Herminian gulf, situated S.E. of the Argolid peninsula. See Hermione.

HYDRELEON, ὑδρελεόν, compound of ὕδωρ, water, and οἶος, oil, in Pharmacy, a mixture of common oil and water.

The hydrea was taken internally to excite vomiting; externally it is anodyne, and promotes suppuration.

HYDRETEROCELE, a term in Surgery, denoting a hydronecrosis complicated with an intestinal hernia. Hydronterocele is composed of three Greek words, ὕδωρ, ὕδωρ, water, ὑδρετής, an intestine, and κελή, a tumour. See Hydrocele.

HYDRIA, in Ancient Geography, an island of the Adriatic sea, placed by P. Mela before the Electrides.

HYDRIA, or Idris, in Geography, a town of Germany, in the duchy of Carniola. N. lat. 46° 14'. E. long. 14°.

HYDRIA, in Mythology, the name given by the Egyptians to the god of the water, which they represented by a vase, perorated on all sides. According to Vitruvius (ib., v.) the priests upon certain days filled this vase with water, adorned it with great magnificence, and then placed it upon a kind of public theatre, where all prostrated themselves before the vase, with hands lifted up to heaven, and gave thanks to the gods for the benefits they received from this element. The intention of this ceremony was to teach the Egyptians that water was the principle of all things, and had communicated life and motion to every thing that breathes.

HYDRIAPHORES, compounded of ὕδωρ water, and ψιθ, I carry, among the Athenians, a designation given to wives of strangers residing in Athens.

They were thus called, as being obliged during the proceedings of the festiva Panathenaea, to carry vessels of water. Potter, tom. i. p. 56 and 401.

HYDRIAS, in Ancient Geography, a country of Asia Minor, in the vicinity of the river Marathus. Herodotus.

HYDRIUS, a name given by some authors to the epithelium, or serpentine-lone.

HYDROCANISTERUM, a fire-engine; or a machine which spouts water plentifully, and with force; need to be applied to the extinguishing of fires, and conflagrations of houses, &c. We have various contrivances to this effect: the first, and which is, as it were, the basis of all the rest, is a pump inclosed in a cistula, or wooden vessel filled with water, and mounted on wheels; the pump being wrought with long levers which come out of the cistula: and the water it raises directed to the place by means of a jointed tube.

The Dutch and others use a long flexible tube of leather, fall-cloth, or the like, which they carry or conduct in the hand from one room to another as occasion requires; so that the engine may be applied where the fire is only within doors, and does not burn out to expose it to the external action. To improve on this original fire-engine, they have since contrived to make it yield a continued stream; by substituting a forcing or preffing pump in lieu of the sucking pump. See Fire-Engine, and Forcing Pump.

HYDROCANTHARUS, in Entomology. See Dys- ticus Marginalis.

HYDROCARBONATE GAS, in Agriculture, an aerial fluid formed during the decomposition of water, which is said to be useful in promoting the progress of vegetation. It is supposed by the author of the work entitled "Phytologia," that during the process of putrefaction "carbon is not only converted into carbonate acid, but there appears to be a decomposition of water, as is known by the smell of hydrogen; and it is probable that this inflammable body may unite with carbon, as in hydrocarbonate gas, and thus render them both soluble in water, and alterable by the vesicles of vegetable roots, without their passing into an acid or gaseous form, and may contribute much to the nutriment of vegetables." This hint requires the further attention of the philosophical agriculturist.

HYDROCARDIA, a term invented by Hildanus to express a serous, faious, or puredulent tumour of the peri-cardium.

HYDROCELE signifies, in Surgery, any preternatural collection of water in the feromum. The term is derived from ὕδωρ, water, and κελή, a tumour. In this disease the fluid may occupy various parts of the feromum. In some cases it is situated in the cellular membrane, which affection receives the appellation of hydrocele seroticus. In most instances it is contained in the tunica vaginalis testis. In some examples it is lodged within the cistula of the spermatic cord; in others it is included in a preternatural cyst; occasionally the water is contained in a true hernial sac; therefore we have five different kinds of hydrocele distinguished by the particular situation of the fluid.

Hydrocele Seroticus—The first species, namely, the hydrops feroticus, is nothing more than an edematous swelling of the feromum. The water is diffused throughout all the cellular membrane of this part of the body, causing every where an equal dilatation, so that the raphe is not pushed out of the central situation which it naturally holds. The swelling has all the character of edema; the preffure of the end of the finger makes an impression upon it; the surface of the feromum is smooth and shining, without any velvett of the corruptions; the part retains its natural colour, is generally very soft, and has a cold feel. In most cases the prepuce is also affected with a similar form of swelling, so that the patient is actually troubled with a phymosis. In certain instances vehicles make their appearance on the interior parts of the penis. We may add, that the tumour is quite free from pain. In some cases one side of the feromum is more dilated than the other, and, consequently, the raphe is not situated in the middle. It is deferving of notice that women are sometimes affected with a similar swelling of the labia.

The hydrops feroticus is generally a symptom of another constitutional disease, especially of aleances and anaesthesia, in which event it is commonly attended with an edematous swelling of the feet. However, it is occasioned quite a local disease; and in this case it is usually a consequence of pressure upon the returning veffels, produced by a dilated thigh-bone, a badly made truss, an indurated omental hernia, &c. Sometimes the disease is noticed in new-born children, and it has been observed to follow contusions of the feromum, and exposure either of this part, or of the whole body, to certain degrees of cold.

An analogous disease may proceed from an extravasation of urine in the cellular membrane of the feromum. This particular case is sometimes the consequence of a retention of urine. When the left affliction has attained a high degree, gangrenous specks are apt to be formed on the pell-
HYDROCELE.

rior and inferior parts of the bladder, so as to let the urine escape into the cellular substance of the perineum and scrotum. In this instance the swelling of the latter part originates suddenly; and in proportion as it increases, all the symptoms of a preternatural dilation of the bladder undergo a diminution. The urine sometimes passes through an ulcerated aperture in the urethra into the cellular membrane of the scrotum. Hence fistula in perineum may be attended with this fort of extravasation. When, also, by external violence the tunica vaginalis has been buried, while distended with water, the fluid has been known to escape from the cavity of that membrane into the cellular substance of the scrotum, the cæfure changing at once from a common hydrocele into an hydrops scroti. Lastly, we have to remark, that a similar extravasation of fluid sometimes happens in the palliative operation for the ordinary hydrocele, when the puncture is executed with a lancet, and the opening in the skin happens to slip away from that in the tunica vaginalis, while the water is flowing out.

In the treatment of the hydrops scroti, it is always an indication to remove the causes of the disease, whether they are of a local or general nature. When a dropfy of the abdomen is fortunately cured by medical means, the hydrops scroti spontaneously disappears. The swelling of the scrotum, likewise, proceeding from the preffure of an ill made trufu, a dilated thigh-bone, &c. will subside as soon as such preffure is removed. But surgical writers appear to coincide in opinion, that caifes may prevent themfelves in practice where local treatment is indifferently proper. An infance of this kind may be where the general or local caufe does not admit of a removal in a complete or sufficiently speedy manner, and where the tumour of the scrotum is attended with ferior inconvenience, or any degree of danger. Thus, when urine is effufed into the scrotum an immediate operation is proper, in order to avert inflammation, suppuration, floughing, and fulture, effects which would otherwise quickly follow. In caifes of the common hydrocele of the tunica vaginalis, eryfipelatous inflammation, ulcerations, and gregarious complaints may occur when the swelling is exceedingly large. The prepafe is sometimes fo swollen that the urine cannot escape from the orifice of the urethra. Yielding as the integuments of the scrotum are, they may yet be burft by being exceffively dilated with fluid, as the obfervations of Mr. Warner confirm. Local means are alfo obviously requisite whenever the hydrops scroti arises from a local caufe.

The most common and effeffual means of relieving the hydrops scroti is letting the fluid out of the cellular membrane by suitable punctures. In a few caifes, indeed, a milder plan will answer the purpofe. The complaint in new-born infants may ufually be cured by bathing the scrotum with warm wine. The hydrops scroti, conquefent to a bruife, or exposure to cold, may in general be very soon difpafhered by the ufe of a alfufenfory bandage, and repeatedly washing the tumour with brandy, lime-water, wine, vinegar, or any decoction of astringent and aromatic herbs. The fame remedies will alfo be found to avail when the swelling remains after its caufe has been removed. When the tumour is exceedingly large, and the symptoms prefling, the furgeon is not to confume time in the trial of these applications, but immediately make the neccessary punctures. If urine should happen to be the fluid in the cellular membrane of the scrotum, proper incifions fhould be directly made for its escape, left inflammation, abcftces, and gregarious itchife infue.

The fluid of hydrops scroti may be difcharged either by an incifion or a puncture. Five or six superficial fcarifications with a lancet will in general be found to answer the purpofe. If such openings should be closed the day after making them, before all the fluid has been discharged, the practioner is called upon to ufe the lancet in the fame manner again. When incifions are preferred, it is customary to make one about an inch long on each fide of the raphe, and deep enough to extend through the skin into the cellular membrane. Scarifications are commonly deemed the moft ad-
HYDROCELE.

ture on the right side of the ferotum in performing the 
palliative operation, notwithstanding the collection of fluid 
may be situated in the cavity of the left tunica vaginalis, and 
vite versa. Probably this unusual shape of a hydrocele may 
be caused by tight breeches or the pressure of the fulguratory 
bandage. The larger the tumour is the rounder does its 
figure become; but in some cases the shape is very different 
from what it is in others. Hydroceles have been observed 
to have occasionally quite a cylindrical appearance. The 
tumour is occasionally divided by a sort of contraction. 
When a hydrocele is the consequence of inflammation, the 
tunica vaginalis is sometimes adherent in different places to 
the tunica albuginea, and of course the swelling has an ir-
regular knobby shape.

The tumour feels like a bladder distended with water-
In its commencement it is soft and yielding; but the tension 
and hardness increase in proportion to the quantity of fluid, 
and the quickness with which it has accumulated. It de-
serves attention, however, that there are some hydroceles of 
considerable magnitude, which are so remarkably soft that 
they may be made quite flat by pressure, and allow the testes 
to be plainly felt. The freer the swelling is from tension 
the more evident is the fluctuation; but even in cases which 
are excessively tense a certain degree of fluctuation can be 
distinguished on applying the palms of the hands on opposite 
ides of the tumour. Schmucker has seen hydroceles which 
felt as hard as a farceole, and Saviard mentions their being 
occaasionaly attended with the hardcns of horn. In such 
instances the tunica vaginalis is in general thickened and 
indurated in an extraordinary degree, and, in certain cases, 
that membrane, instead of containing merely an aqueous se-
cretion, has been found to include cysls or vesicles filled 
with a yellow fluid.

When either the patient himself or the surgeon handles 
the tumour, the fame kind of feefation is communicated to 
the fingers, whatever part of the swelling is touched. The 
surgeon perceives every where the fame kind of feel as he 
would be sensible of in handling an elastic distended bladder, 
and the patient suffers no pain from any manual examination 
of the disease. The whole circumference of the swelling is 
smooth and even, except just at one place, which is where 
the testis is situated, and is usually at the hinder and middle 
part, though not unfrequently at the upper portion of the 
tumour. In such situation the surgeon may feel an inequality 
and an indurated hardnes, and when the part is comprcssed the 
patient is afflicted with the peculiar pain which is always 
produced by squeezing the testis. This gland may almsot 
always be felt at the back part of the swelling, at various 
heights, according as the tunica vaginalis happens to have 
been dilated upwards or downwards by the increasing quan-
ty of the fluid. B. Bell twice saw the testis in front of the 
tumour. The same gland, though at the back part of the 
swelling, has been found adhering to the fore part of the 
tunica vagiis in, in consequence of inflammation, which was 
preceded to the hydrocele. Mr. Elfe had an opportunity of 
feeling a case, where the oval swelling of a hydrocele was 
in an horizontal position from before backwards, while the testis 
could be plainly felt at the bottom of the ferotum.

When the end of the finger is pressed upon the hydrocele 
of the tunica vaginalis, it does not leave after it any impres-
sion or dent. How large soever the swelling may be, the 
skin of the ferotum always retains some velvets of the cor-
rugations, or, at least, is never so smooth and shining as it 
is in the case of hydrops ferotis. Frequently, when the tumour 
has acquired a considerable size, the penis becomes retrac-
ted in such a manner, that the prepuce has somewhat the ap-
pearance of a navel at the upper and forpart of the ferotum. 
The diseale is entirely free from pain, except when it in-
creases very quickly, in which circumstance a degree of un-
comfort is experienced in the swelling, at the same time that 
painful sensations are felt in the loins, probably excited by 
the weight of the tumour, when the patient has been a long 
while in a fladling posture. We find, therefore, that such 
pain may be relieved by the patient's lying down. As this 
pecies of hydrocele commonly affects only one side, or 
finite, when in a few instances, it happens at the same time 
on both sides of the ferotum, it is not equally large on each 
side. The whole circumference of this swelling has been never 
exactly in the middle. The integuments of the ferotum have their natural colour. Most 
hydroceles of the tunica vaginalis are attended with a certain 
degree of transparency, and the knowledge of this circum-
stance is of infinite importance to the practitioner, since it 
will often enable him to form an accurate judgment respecting 
ambiguous cases. In order to learn whether the swelling is 
transparent, the chamber should be darkened, while a lighted 
taper is held just on one side of the ferotum, while the sur-
geon looks at the other, which ought to be in the shade. It 
is necessary, however, for every surgeon to be aware that 
transparency is by no means a confluent symptom of a hydro-
cele, and is never present, either when the tunica vaginalis 
is preternaturally thick and indurated, or when it is filled 
with a dark turbid fluid, or cysts refilling hydatids.

By paying attention to the foregoing symptoms, the sur-
geon will be able, in all ordinary cases, to discriminate the 
hydrocele of the tunica vaginalis from every other kind of 
tumour to which the ferotum is liable. But yet it must be 
allowed that there are cases where the diagnosis is attended 
with considerable difficulty, certain diseases having so much 
imititude to the hydrocele of the tunica vaginalis, that they 
may deceive the most attentive and experienced surgeon. 
One of such cases is the farceole, which has the same 
shape as the hydrocele, and, like it, is situated at the lower 
end of the peripatic cord. The chiefly difference, therefore, 
together with the two diphasea, seems to be, that the farceoles 
are hard, while the hydrocele has a soft, yielding, elastic feel, 
accompanied with a fluctuation. The farceole itself, how-
ever, is not always remarkably hard, and the hydrocele is 
now and then very indurated. The farceole, indeed, is not 
transparent; neither is the hydrocele in certain instances; 
and there are cases where a mistake may easily be made.

Still, with due attention, both diseases may be determined with 
tolerable precision. The farceole, when held in the 
surgeon's hand, seems heavier than the hydrocele. The 
testis is seldom equally indurated everywhere, and the far-
ccele is usually much fatter in some places than others. 
The hydrocele presents the same kind of feel at every point, 
except behind, where the testis is felt. When, in the case 
of hydrocele, preffure is made in this latter situation, the 
patient experiences a much more acute sensation than when 
the preffure is made upy on any other part of the tumour; 
but in the example of farceole, the patient commonly has the 
same kind of feel, let the preffure be applied to any part of 
the swelling whatsoever. The hydrocele may be compared 
with a bladder full of water, the surface of the tumour being 
everywhere smooth and even, except in the situation of the 
testis. This gland itself, when hardened, seldom undergoes 
a regular, uniform enlargement; but generally has a sur-
face more or less uneven. When the upper portion of the 
peripatic cord can be felt, and it seems quite hard and 
thickened, the surgeon has reason to suspect that the case is 
a farceole. Lastly, though a hydrocele, when gently 
handled, may seem to be considerably hard; yet, on being 
more strongly compressed, it will generally betray a soft 
elastic
HYDROCELE.

A hydrocele is sometimes conjoined with a fishy enlargement of the testis, which case is well known among surgeons under the appellation of hydro foarcocele. As the diseased testis is here surrounded with water, it cannot be felt nor examined by the fingers. But the quantity discharged by the vesiculae seminales is far too small to account for the aqueous fluid. The liquid is generally a faint yellow, free from excreta, and of a less density than that from the vesiculae seminales. This, however, is prone to be misinterpreted, for in a dilated cavity, said to be hydrocele, the testis is often found to be meagre in quantity. These observations are especially applicable to the case of the vesiculae seminales. The former condition, when compared with a dilated vesicula spermatica, is a remarkable difference. The operation of aspiration of water from a dilated vesicula spermatica is attended with the most disadvantageous consequences, and is fraught with the greatest danger. The operation of aspiration of the fluid from a dilated vesicula spermatica, is attended with the most disadvantageous consequences, and is fraught with the greatest danger.

It is a disease from which no time of life is exempt; not only adults are subject to it, but young children are frequently afflicted with it, and infants sometimes born with it. The great Mr. Pott professed himself incapable of determining the immediately producing cause. Ruyfch thought that the complaint might proceed from a varicocele of the spermatic cord. What real foundation there may be for such conjecture, Pott could not say, and, at the same time that he acknowledges the frequently varicocele affection of the spermatic vessels in cases of hydrocele, he seems to consider it as unproved whether such state be a cause or an effect of the disease. It is also remarked by Mr. Ramden, that though we often find the hydrocele prevalent with the varicocele, we much more frequently meet with this last disease, even in its most advanced state, unaccompanied by any accumulation of fluid within the sacculus. (Practical Observations on the Scrotocele, &c. p. 19.) The hydrocele of the tunica vaginalis may frequently, perhaps commonly, be regarded as a disease altogether local, and dependent upon local causes. According to surgical writers, contusions of the scrotum often give rise to the complaint, and hence it is said to occur with particular frequency in persons who are in the habit of riding a great deal on horseback. In such cases the fluid is sometimes formed by the breaking of vesicles. Of the fluid, it has been observed that the part of the spermatic cord by an ill constructed truss, or by an indurated dorsal hernia, may also be a cause of an hydrocele. Sometimes the latter malady is joined with a farcocele, when it may be considered only as an effect of the disease of the testis. A hydrocele may likewise originate from an inflammation of the testis gland. In some instances the disease appears to depend upon general and less manifest causes. We are informed of its having arisen in the space of four days, after exposure to cold. (See Richter's Anfangsgründe der Wundartzneykunst, Band 6. p. 67.) Warner and other authors have taken particular notice how prevalent the disease is in warm climates, and they make mention of patients who got well on removing from a hot into a cold country, but suffered relapses on their return into a warm part of the world. We deem the opinion, that hydroceles are never connected with a vesical cauze, entirely destitute of foundation.

Mr. Ramden has recently advanced a new doctrine respecting the cause of hydroceles. This experienced surgeon has established three forms of the disease, as occurring within the tunica vaginalis; namely, the acute, the spurious, (hydro-farcocele), and the true, or chronic hydrocele. He endeavours to prove that all these cases may be dependent upon excitement within the urethra. He remarks, that the testicle will become hardened and enlarged, and that the sacculus of the tunica vaginalis will be distended with watery fluid, in consequence of various degrees of excitement within the urethra, from the irritable and acutely painful irritate, down to that cedated, faded, and local derangement of the membrane, which is totally free from pain, until it is pressed upon by the bungie, and which may exist for years without the patient being conscious of its presence.

"It cannot therefore be unreasonable to suppose that an habitual susceptibility of the whole membrane of the urethra may, in some instances, be induced by general or local causes, and although it create no conscious sensation to the patient, may have the power of gently provoking the excitation which necessarily follows any such diseased state of these parts as prevents the due secretion of it. On the contrary, if the quantity deposited be too large, or if the regular absorption of it be by any means prevented, it will be gradually accumulated, and, by distending the containing bag, will form the disease in question."

elusive feel, which is never the case with an indurated farcocele.

A hydrocele is sometimes conjoined with a fishy enlargement of the testis, which case is well known among surgeons under the appellation of hydro foarcocele. As the diseased testis is here surrounded with water, it cannot be felt nor examined by the fingers. However, when an unusual degree of hardness is perceptible at the back part of the tumour, where the testis is situated, or when the upper portion of the spermatic cord is found to be quite indurated, the surgeon has reason to suppose that the testis is affected with farcocele. The latter is commonly the original and principal disease, the hydrocele first coming on subsequent to the enlargement of the testis. To the experienced practitioner, this circumstance often affords useful light. We learn from the observations of that very excellent surgeon, Mr. Warner, that omental hernia in young children are sometimes so transparent, that they may be mistaken for hydroceles. But all the other ordinary characters of these fluid swellings are absent. A cystocele, or hernia of the urinary bladder, has some resemblance to a hydrocele, though the two affections may easily be distinguished from one another by paying attention to the particular symptoms of each, as described in a foregoing part of this work, (see Hernia), and in the present article.

The diagnosis is always apt to be attended with a degree of obscurity, when the hydrocele is complicated with other diseases of the scrotum. Sometimes it is conjoined with a hernia. On other occasions, the hydrocele of the tunica vaginalis exists in conjunction with one of the spermatic cords. The surgeon can only acquire a perfect knowledge of such cases by paying close attention to the peculiar symptoms of each of the diseases. When the requisite information cannot be thus obtained, it may often be procured by advertins to circumstances which prevented themselves in an early stage of the case; for frequently the hydrocele is at first simple, and does not become complicated till an advanced period. The nature of the case is often elucidated on the palliative operation for the hydrocele being performed, as the other disease of the scrotum becomes quite obvious immediately the fluid is discharged from the tunica vaginalis.

The species of hydrocele, now engaging our attention, continues for a long while unattended with any severe inconvenience, or peculiar symptoms: it only annoys the patient by its size and weight. When it is exceedingly large, the penis is drawn completely back, so that the urine dribles over the forepart of the scrotum, and, unless particular care be taken to maintain cleanliness, is liable to excite inflammation and painful excoriations. When a hydrocele is the consequence of an inflammation of the testis, the fluid generally accumulates with great quickness. But the progress of the disease is occasionally so slow, that the palliative operation has not been required till twenty years after the commencement of the disorder. In general, the water only collects in one tunica vaginalis; sometimes in both. In the latter kind of case, a preternatural communication has been noticed between the opposite sides of the scrotum, though we believe such a circumstance is very uncommon. See Richter's Anfangsgründe der Wundartzneykunst, Band 6. Kapitel 5.

The hydrocele appears to be one of those diseases, the causes of which are far from being well understood. In a natural, healthy state, the cavity of the tunica vaginalis always contains a small quantity of a fine fluid, exhaled from capillary arteries, and constantly absorbed by vessels for that purpose. This fluid, in the natural small quantity, serves to keep the tunica abuminosa moist, and to prevent a coagulation between it and the vaginalis; a consequence which almost
HYDROCELE.

The prevalence of hydrocele in the East and West Indies, instead of being attributable to the relaxation of the climate, may more reasonably be referred to the constant excitement to which the urethra is exposed from the habits of the table; since it is well known that, in those hot countries, every individual indulges in high-feasted dishes, and in the most stimulating description of diet.

The frequency of the hydrocele being present with the varicocele may also be satisfactorily explained, by referring to that state of continual excitement, which is kept up by the dilatation and weight of the loaded vessels. In the more advanced states of varicocele, nothing is more common than an habitual gleet or weeping from the urethra, which is occasioned by the dragging of the varicocele vessels; and it certainly appears not difficult to suppose, that such excitement in the urethra, when once established, may in its turn re-act upon the testicle, and produce a case of hydro-varicocele." (P. 193—201.)

For the cure of the hydrocele of the tunica vaginalis, a surgical operation is generally necessary, as it is only in a few instances that the complaint yields to internal or external remedies. The observations of writers prove, however, that in young children the disease may sometimes be dispersed by emetics. A boy, twelve years old, was cured of a hydrocele by means of the decoction of vinegar, the fawntnion lotion, and repeated purgative doses. (See Richter's Chr. Bibliothek, 5. b. p. 125, 9. b. p. 593.) Morand succeeded in curing several hydroceles by making an issue on the testicle; and Douglas found similar success from placing an issue near the groin. Schenckler dispersed a hydrocele by fumigating the scrotum with vinegar every morning and evening, and in the intervening time compresses wet with the same fluid. In the course of a few days the tumour subsided, the hydrocele emitting a large quantity of perspiration. Warner frequently cured hydroceles in young subjects by means of purgatives, and diluting and purging applications. Mohrenheim succeeded in dispersing a hydrocele, which arose from exposure to cold. (Richter's Anfangschr. &c. Band 6. p. 68.) Mr. Keate has recommended the following lotion, as an efficacious remedy: a Sal. Ammon. Pulver. f. Acet. Spir. Vin. R. et al tit. iv. Misce. Compresses, wet with this mixture, are to be laid upon the testicle, and kept there with a bag-trous. They should be dipped in the liquid three times a day. Mr. Keate affirms us, that when this plan is properly followed up, the water of the hydrocele not only gradually disappears, but that it does not accumulate again, and the cure is radical and permanent, if the application be continued about a month. This method may be tried, either while the tumour is filled with water, or after the fluid has been let out. In the first instance it excites the absorption of the water; in the second it produces a new collection. When the application happens to make the integuments red or painful, it must be left off a few days.

The observations of Sir James Earle, however, tend to evince, that the preceding practice does not always answer, and is not to be depended upon. From the account which Mr. Ramden has lately published, of the hydrocele being connected with a morbid state of the urethra, one might suppose that the disease would yield to the proper treatment of this last canal. This gentleman remarks, however, that in cases of chronic hydrocele, the use of the bougie is not attended with the same degree of success as in the examples of the acute and purulent forms of the complaint. We may again state, that by a purulent hydrocele is meant a collection of fluid in the tunica vaginis, accompanied by an enlargement of the testicle. The simple indurated or tumefied part of this gland, unattended with any subversion of its organization, we conceive to be the case, which Mr. Ramden has lately dignified by the appellation of sclerocèle, and which, being sometimes joined with an accumulation of fluid in the tunica vaginalis, conveys an image of purulent hydrocele, or what this eminent surgeon has named hydro-sclerocèle, in order to distinguish the disease from the hydro-scarce where the organization of the testicle is actually more or less subverted. Now Mr. Ramden has endeavoured to prove, that the acute hydrocele, as well as the hydro-sclerocèle, may be cured by treating the urethra with bougies, so as to destroy the morbid irritation in that canal. The sclerocèle of the testicle, whether with or without fluid in its faciculus, yields most readily to the use of the bougie, when the progress of induration in the gland has been most rapid, and the point of irritation within the urethra, on which it depends, is most accessible; but the chronic hydrocele being slow in its progress, and dependant on a much more modified state of derangement in the urethra, is, on such account, very little under the influence of the treatment of that membrane, and must be referred to some other operation for its permanent cure." (P. 202—203.) From a note, it appears to be Mr. Ramden's opinion, that when a tumour of the scrotum presents itself under the external appearances of true chronic hydrocele, and is co-existent with an acutely deranged urethra, and especially if the patient has any dislike to the hydrocele being tapped, the treatment of the urethra by the bougie will always be a fair experiment previous to the letting out of the water. Mr. Ramden can affirm, from his own experience, that it will, in some few instances, prove successful in curing the hydrocele. He thinks it probable, that in the cases in which this treatment succeeded, there might be concealed sclerocèle; but he considers that such a fact would not lessen the propriety of the experiment. When the true hydrocele is not attached with an urethra so obviously deranged, Mr. Ramden believes, that an attempt to cure the complaint by the use of the bougie will only be a waste of time. See Practical Observations on the Sclerocèle, &c. by T. Ramden, surgeon to Chirld's Hospital, &c. &c.

For relieving the present disease, two operations are practised; one called palliative, the other radical. In the first, the design of the surgeon is merely to discharge the water, which usually accumulates again, and the malady returns. By the second he permanently frees the patient from the complaint, and hinders any relapse, this object being accomplished by excising an inflammation of the whole surface of the tunica vaginalis, and a consequent universal adhesion of this membrane to the testicle. In short, the cavity of the tunica vaginalis, which is the seat of the disease, is thus oblitered. This is the commonly received opinion; but at the same time we are not unaware of a different sentiment upon this same point having been lately advanced by Mr. Ramden, who has added cases in which, from the transparency manifested in the scrotum, a considerable time after the radical operation

had...
HYDROCELE.

had been performed, the doctrine of the disease being always cured, by the obliteration of the cavity of the tunica vaginalis, is called in question. The surgeon cannot invariably and indiscriminately undertake either of the preceding operations, at his own pleasure, with equal prudence and propriety. The palliative operation is entirely exempt from danger, and when a sufficient quantity of fluid is collected in the tunica vaginalis may be safely undertaken, even though the testis may not be altogether undisposed, nor the patient in good health. On the other hand, the radical operation, executed in any way whatsoever, demands more caution, and if done in improper cases, may be followed by dangerous and unpleasant consequences. In determining which method is to be adopted, the surgeon should attend to the following directions.

When the hydrocele is exceedingly large, it is not advisable to perform the radical operation, the great dissection which the parts have already suffered placing them in not the most advantageous state for bearing inflammation. It is much better, in a case of this sort, to be at first content with merely letting out the water, and to undertake the radical operation afterwards, when a moderate quantity of fluid has accumulated.

When any suspicions are entertained of the testicle being diseased, the surgeon must restrict himself to discharging the water, a plan which can always be securely undertaken, though the testicle may not be found, and has the advantage of enabling the practitioner to feel and examine distinctly this latter part.

Should any radical operation be done, unpreceded by tapping the tumour, and the testicle prove to be affected with farcocele, catarrh ought to be immediately performed, since the irritation would exist, and all probability, bring on a malignant change in the disease of the testicle. If an attempt at the radical cure should have been made, and the testicle be found thus diseased, yet, without the same admitting of the performance of catarrh, the patient is put into a very unpleasant and precarious condition.

When the patient's health is very bad, the radical operation ought not to be undertaken, for fear of inducing alarming symptoms. This observation, however, must not be extended to a class of subjects, those, though not in health, are neither affected with extreme weakness, nor any profuse indigitation. The palliative cure, being free from danger, may be undertaken in almost any cases and circumstances.

When the hydrocele is complicated with other diseases of the scrotum, it is a wise maxim to be satisfied in the first instance with simply discharging the fluid. The surgeon can then examine more accurately the nature of the other disorder, and, at a future period, attempt the radical cure of the hydrocele, if judged prudent, with greater facility.

The intention of this proceeding is to relieve the disease for the present, by discharging the accumulated fluid. The operation by which the water is let out is a very simple one. The only circumstances requiring our attention in it are, the instrument wherewith we would perform it, and the place or part of the tumour into which such instrument should be palled.

The two instruments in use are the common bleeding lancelet, and the trocar.

"The former having the finer point (says Mr. Pott), may possibly pass in rather the easier, though the difference is hardly perceptible, but is liable to inconveniences, to which the latter is not. The trocar, by means of its cannula, secures the exit of the whole fluid, without a possibility of prevention, the lancelet cannot. And, therefore, it frequently happens, when this instrument is used, either that some of the water is left behind; or that some degree of handling and squeezing is required for its expulsion; or that the introduction of a probe, or a director, or some such instrument, becomes necessary for the same purpose. The former of these may in some habit be productive of inflammation; the latter, belonging what with which the patient himself or a person, and multiplies the necessary instruments; which, in every operation in surgery, is wrong. To which it may be added, that if any of the fluid be left in the vaginal coat, or infiltrates itself into the cells of the scrotum, the patient will have reason to think the operation imperfect, and to fear that he shall not reap even the temporary advantage which he expected. The place where this puncture ought to be made is a circumstance of much more real consequence; the success of the attempt, the case, and even sometimes the safety of the patient, depending upon it.

"All the anterior and lateral parts of the vaginal coat are loose and detached from the albuginea; in its posterior and superior parts, these two tunics make one; consequently the testicle is, as it were, all to the posterior and superior part of the cavity of the scrotum, therefore, the water or fluid can never get quite round it. This being the state of the case, the operation ought always to be performed on that part of the tumour where the two coats are at the greatest distance from one another, and therefore, where the fluid must be accumulated in the largest quantity, and never on that part of it where the fluid cannot possibly be. The consequence of acting otherwise, must not only produce a disappointment, by not reaching the said fluid; but may prove, and has proved, highly, and even fatally malicious to the patient." (Pott on the Hydrocele.) In short, it must be plain to every person, who has any knowledge of the present disease, that in all common cases, the proper place for making the puncture is at the lower and fore-part of the scrotum. It ought, however, to be understood, that surgical writers make mention of examples, in which the hydrocele has an unusual shape, in consequence of the pressure of a bag-truss, &c. Inflammations have been observed, in which the hydrocele was of an horizontal oval form, with the testicle plainly perceptible underneath at the bottom of the scrotum. In all such cases, the surgeon should first examine the situation of the testicle, and choose a place for making the puncture, where there will be no risk of injuring the latter part. The oval face of an hydrocele of the left tunica vaginalis, has been known to have to oblique a position, that its bottom could be felt on the right side of the raphe at the inferior part of the scrotum, while its upper end lay on the left side of the scrotum, near the abdominal ring. This hydrocele of the left tunica vaginalis was tapped on the right side of the raphe at the bottom of the scrotum, and as soon as half the fluid had been discharged, the sac became situated quite on the left side of the raphe, the exit of the water ceased, and the cannula fell out. Even in cases where the swelling had the ordinary shape, the testicle has occasionally been seen at the fore-part of the tumour. Hence practitioners should remember, that making the puncture at the lower and anterior part of the hydrocele is not a matter of course; and that it is their duty, in every instance, to endeavour to ascertain the precise situation of the testicle, in order that it may be more certainly avoided. Richter's Anfangsgründe, &c. Band 6, p. 73.

After letting out the water of an hydrocele by the palliative operation, it is prudent to cover the puncture with a bit of lint and a plaster, to keep up the scrotum with a bag-truss, and direct the patient to keep himself quite still for the first twenty-four hours afterwards. The bag-truss gently
HYDROCELE.

gently supports the suddenly relaxed parts, and thus tends to prevent any painful swelling of the testicle, as well as hemorrhage in the tunica vaginalis, and too rapid an accumulation of the water again. Although no painful and inflammatory symptoms usually follow the operation, and the orifice heals in a few hours, like that made in bloodletting, and this notwithstanding the patient neither pays attention to regimen, nor abstains from his ordinary pursuits; yet the contrary sometimes happens. We learn, on the authority of Mr. Pott, that in some habits and circumstances, the puncture inflames and feller. Such setting in is generally superficial only, and is soon quieted by应用 dressing; but it is sometimes so confiderable, and extends so deeply as to affect the vaginal coat, and by accident produce a radical cure. Mr. Pott has likewise seen it prove more troublesome, and even fatal, when the circumstances of the patient, and the case have been particular. The accounts delivered to us by surgical authors confirm, that in persons of bad constitutions, pain, inflammation, and fever are apt to succeed, if the ferom be too much rubbed and agitated. A patient, immediately after the operation, went several miles, and brought on by this means so high a degree of inflammation, swelling, and fever, that the consequence was a radical cure of the hydrocele. (Default, Journal de Chirurgie, tom. I.) Theden has recorded a case where similar symptoms were produced, only in a more severe form. Upon the whole, however, the palliative operation is not very liable to any disagreeable consequences. If pain, inflammation, and fever occasionally arise, it almost always will be found, that the patient has been guilty of imprudent exertion, or that the habit is exceedingly bad. In some instances, these symptoms are to be ascribed to the circumstance of the end of the canul,a having been rubbed against the testicle during the escape of the fluid. An hematocele, which is occasionally produced after the operation, proceeds either from the great determination of blood to the relaxed parts, or from an actual injury of one of the blood-veils of the tunica vaginalis with the lancet or trocar. When, from the colour of the water, there is reason to apprehend that a vein has been wounded, the surgeon may often succeed in preventing any serious collection of blood, by taking care to cover the ferom with cold applications, and support it well with a hog-ťrail. Should he however be unable to hinder such collection from taking place, both the hematocele and hydrocele may be radically cured by laying open the cavity of the tunica vaginalis. See HEMATOCELE.

It is said, that when the tunica albuginea is unfortunately wounded with the point of the trocar, the subsidence of the testis is protruded through the puncture of that membrane, and forms a swelling which may create a necessity for castration. When the trocar happens to injure any varicose blood-veils of the integuments of the ferom, an extravasation of blood in the cellular substance may ensue, and end in ulceration, unless specifically diffiered. But while we are noticing these occasional evils, let us not forget to state, that the palliative operation sometimes proves beneficial beyond expectation, no water collecting again, and the patient remaining for ever afterwards free from the disease. Wifeman and others have advised deferring the puncture till a pint of fluid has collected. On the contrary, Mr. Pott expresses his decided opinion, that when the water is in sufficient quantity to keep the testicle from the influnt, there can be no reason for deferring the discharge; and he contends, that the single point on which this argument ought to rest is this: whether the aborber veins, by which the extravasation should be prevented, are more likely to re-affume their office, while the vaginal coat is thin, and has suffered but little violence from dilatation; or after it has been stretched and dilated to ten, or perhaps twenty times its natural capacity; and by such dilatation is, like all other membranes, become thick, hard, and tough? Mr. Pott believes the probability so much more on the side of the former, that he should never hesitate a moment about letting out the water, as soon as he found that the puncture could be made securely. And, from what has happened within the small circle of his own experience, he is inclined to think, that if it was performed more early than it generally is, it might sometimes prevent the return of the disease.

Although we have given a general preference to the trocar, as the best instrument for tapping hydroceles; we can conceive a few instances in which the employment of a lancet for the purpose might be attended with advantages. Supposing the surgeon to have operated upon a very small hydrocele, which contains only a little quantity of fluid, it is better to use the lancet. The trocar must always be introduced more deeply than the latter instrument, and is therefore more apt to injure the testicle. In such a case, also, there is no danger of the lancet occasioning an hematocele, since the veins of the tunica vaginalis have suffered no dilatation. On the same principle, the lancet ought to be preferred in all cases where the hydrocele is complicated with either a hernia, or an exceedingly large farcocele, and it is impossible to ascertain the exact position, size, and quantity of parts in the scrotum.

Sir James Earle thinks, that the palliative operation ought to be performed at least once on those who determine to submit to the radical method of cure, as it enables the surgeon to examine the state of the testicle, and affords an opportunity of operating in the other way afterwards, when the tunica vaginalis is not more diffiered than is proper. On the Hydrocele, p. 13, edit. 2.

We shall conclude the observations which we have to offer on the palliative operation, with noticing the circumstance of the fluid sometimes not flowing through the cannula of the trocar, or of escaping only just at first, and then stopping, notwithstanding the introduction of a probe. This occurrence may depend on various causes. The fluid in the tunica vaginalis is occasionally as thick and viscid as white of egg. (Warner.) Sometimes the cavity of the tunica vaginalis is divided by several partitions formed of a loose sort of cellular substance. In certain instances, the cavity has appeared to be filled with hydatids, or transparent cysts. Should the patient be in a fit state for the radical operation, it would undoubtedly be right, in a case of the foregoing description, to perform it at once. The plan by injection being here quite inapplicable, the surgeon should introduce a direct or through the cannula of the trocar, withdraw the tube, and, with the aid of the director and a curved bifhoy, lay open the cavity of the tunica vaginalis.

Of the Radical Method of Treatment.—The great object in the radical operation is to produce an entire obliteration of the cavity of the tunica vaginalis, which is the seat of the disease, and thus render a recurrence of the complaint impossible. This purpose has been fulfilled in two manners, viz., by cutting the whole of the tunica vaginalis away, or by exciting such an inflammation of this membrane as makes it universally adherent to the testicle. In the latter method, it is a principal indication to have an effectual, yet not too violent a degree of inflammation. When it is too foreign, or does not extend to the whole of the membrane, it is ineffectual. In the first of these circumstances no cohesion follows, and the operation completely fails; in the second, the tunica
HYDROCELE.

tunica vaginalis only becomes adherent to the testicle at those places where the inflammation exists, while elsewhere a cavity remains, in which the fluid re-accumulates. When there are several such parts, to which the inflammation does not extend, the hydrocele recurs in the form of several distinct swellings, and the water is contained in separate cysts. On the other hand, the inflammation is too violent, when it is such as brings on severe febrile symptoms, and affects the testicle even more than the vaginal coat. The means employed to relieve the necessary inflammation ought always to be calculated to affect the latter membrane chiefly, and the testicle as little as possible; a considerable inflammation of this gland not being essential to the radical cure of a hydrocele, and being invariably attended with more severe symptoms, than those which result from an inflammation of the vaginal coat. With the preceding intentions, various methods of operating have been practiced, the chief of which we shall now proceed to describe.

Incision.—In this plan, an incision of some length is made through the integuments of the scrotum and the tunica vaginalis, by which means, not only the fluid is discharged, but such inflammation excited as ends in a coagulation of the whole of the vaginal coat with the testicle, and, of course, the recurrence of the hydrocele is effectually prevented. This mode of effecting the radical cure of the hydrocele is the most ancient of all, having been described by Celsus.

The operation is performed as follows: the point of a straight bistoury is to be placed on the fore-part of the swelling, while the back of the instrument is to rest against the index-finger of the surgeon's left hand. The knife is to be pushed into the tumour, and an opening of such size immediately made as will let the operator introduce completely into the tunica vaginalis his finger, on which the further course of the bistoury is to be directed. Directly the first puncture is made, the fluid is apt to gush out all on a sudden, leaving the tumour collapsed, and the operator incapable of easily introducing the instrument, with which he purposes to enlarge the first wound. In order to prevent any inconvenience of this kind, surgical authors direct us to place the end of the left index finger close behind the point of the knife, and to take care to make it pass into the wound immediately behind the latter instrument. This being done, the surgeon, with the aid of his left thumb, can take hold of the investments of the hydrocele, and hinder a closure of the opening just made. A blunt-pointed crooked bistoury is then to be introduced, and, guided by the fore finger, will serve for enlarging the incision downwards and upwards, in such manner, that the wound may extend down the middle of the front of the tumour to its lower part. When the hydrocele is small, or complicated with a faradice, or hernia, or when any doubts exist concerning the real nature of the cyst, writers advise us to let the first incision only divide the integuments of the scrotum, and then to open the tunica vaginalis separately.

Should any modern practitioner choose to perform this operation, he would find it very advantageous to make the first opening into the hydrocele at the upper part of the swelling, as all the fluid would then not make a sudden escape, to as to occasion a collapse of the tumour, and difficulty in effecting the necessary dilatation of the wound.

The incision must be carried to the bottom of the tunica vaginalis, or else blood and matter will be very likely to lodge there, and create trouble.

The cavity of the hydrocele having been thus laid open, is to be dressed with soft pieces of lint; these are to be covered with a pledget; and a supplenyor, or T bandage. The dressings are to be changed at proper intervals, until the part is completely healed.

Much more might be said concerning this method of effecting the radical cure of the hydrocele; but we suppress many particulars, conceiving them to be superfluous in the present almost exploded state of the operation. Whoever will take the trouble to read the accounts of this plan, as delivered to us by surgical writers, will find that, according to Monro and Arrell, its consequences are sometimes dangerous, and even fatal, while, in other instances, the inflammation of the testicle has been so violent, as to end in suppuration. (See Richter's Anfangen, &c. Band 6, p. 92.) Hence it has been commonly found proper to employ a strict antiphlogistic treatment, which is acknowledged to have occasionally defeated the very object of the operation, by preventing the kind of inflammation necessary for the completion of the radical cure. Thus, fever as the method is, it is uncertain, and its failures are confirmed by the testimony of Bertrand, Sabatier, and Sir James Earle. We will not dwell upon the objections which might be urged against the practice, from the disagreeable and dangerous bleedings which sometimes follow the operation, or the painful excoriations which frequently arise. The method has no advantage over a milker operation, which we have to recommend, and it is altogether feverish, as well in its performance as in its consequences.

We should, however, have deemed it our duty to enter into a more particular detail of the reasons against the plan, had not the disparity into which it has now sunk rendered this task unnecessary.

Extirpation.—It sometimes happens, after performing the foregoing operation, that the tunica vaginalis is found in a thickened and indurated state. Certain writers and practitioners have fancied, that when this is the case, such an inflammation as is essential to the radical cure will not take place. Under this impression, they recommend scarifying the inner surface of the tunica vaginalis, or even cutting this membrane entirely away. Many eminent surgeons of past times have adopted the latter proceeding with success, as for instance, Douglas, Saviard, White, Gooch, and Louis. Indeed, it was remarked by Bertrand, that the symptoms are generally milder after the excision of the tunica vaginalis, than after a mere division of it. The method consists in defacing away portions of the membrane, after laying open its cavity; care being taken not to cut too closely to the testicle, for fear of exciting a violent degree of hernial hemorrhage.

Certainly we can conceive a case in which the tunica vaginalis may be so disfigured, as to justify the tedious and painful plan of removing a part of it by incision. But an incision of this kind must be very uncommon; and the observations of Sir James Earle confirm, that the radical cure, by means of an incision, can be accomplished without any excision, notwithstanding the tunica vaginalis is thickened. The method of extirpation, however, is not only objectionable, as being productive of avoidable pain; it is liable to bring on troublesome hemorrhages both during and after the operation, and to be followed by furs and fistulous abscesses, which are a very long time in healing.

Tent.—Experience having shown that, in many instances, moderately stimulating the tunica vaginalis will bring on a sufficient inflammation of this membrane to effect a radical cure; and likewise, that the common palliative operation, done with a trocar, is sometimes followed by the same beneficial consequence; attempts have been made to free the patient permanently from the disfave of milker methods than those which we have just now been describing. After the palliative operation with a trocar, Monro suggested using the
the cannula in the wound until the necessary inflammation had been excited, and he assures us, that in this manner he often accomplished a radical cure with the utmost success.

Warner used to puncture the swelling with a lancet, and, after letting out the fluid, introduce into the opening a tent, which was left there until an adequate degree of inflammation had come on.

The latter mode of operating has been the most extensively adopted. It is executed as follows: a puncture is made with an abract-lancet in the anterior and inferior part of the tumour, and the fluid discharged. A tent is then introduced into the aperture, so as to lie between the tunica vaginalis and the tefficle. The opening is next covered with a pledge. The wound in the integuments and vaginal coat ought to be about an inch and a half in length. We are also advised by some authors to introduce the tent while the water is making its escape; as, in consequence of the way in which the sac occasionally collapses, the operator may afterwards have trouble in getting the tent into the tunica vaginalis, and, perhaps, force it into the cellular fulness of the fertom, instead of the proper situation, in which circumstance the attempt at a radical cure would fail. The tent ought to be at least an inch long, have a ligature attached to it, and be made either of sponge, or a lint of lint. The latter can be bent introduced by means of a probe. A fresh tent should be put in every day; and the length and thickness of it may be gradually diminished. This mode is to be followed up, until an effectual inflammation is excited, which commonly happens on the second or third day, though sometimes later. The tent is afterwards to be discontinued, and an emollient poultice applied. In general, suppuration very soon commences. Occasionally abscesses form, and require to be opened. Frequently the symptoms are so mild that the patient scarcely finds it necessary to keep his bed; but sometimes they are so severe, that a rigorous employment of antiphlogistic treatment is indispensible.

France is said to have made the first mention of the cure by the tent. The method has been practised by a long list of eminent surgeons of later date; but it has now been abandoned by all practitioners in this country. Mr. Pott objected to the cannula, that it was very inconvenient, as, by reason of its fixity, it hurt the tefficle whenever the patient moved; consequently he preferred a tent or bougie; but, according to his account, the method is attended with a considerable degree of uncertainty.

Cauter.—The ancients employed cautery for the purpose of forming in the tunica vaginalis such an opening as would extend the whole length of this membrane. The common consequence of the method was a train of severe and violent symptoms, and, on this account, the practice was for a long while entirely given up. It was afterwards revived, by reason of the favourable reports made of it by Eöe, Acrell, &c.; but these later surgeons did not use the cautery exactly in the same way as the old surgeons, as their object was not to make an opening through the vaginal coat with it, but only to irritate the membrane, and make it inflame. Cautery has this effect, when employed according to the following directions.

The cautery must be applied to the inferior and anterior part of the fertom, and, in order that it may not act too extensively, the part should be covered with a piece of plaster, in which a hole has been cut. When the hole is about as large as a half guinea, the escar produced by the cautery will generally equal a guinea in size, which, according to Mr. Eöe, in all common inflations, will be quite large enough. Other writers have advised making a more extensive scotch, and to proportion its size, in some measure, to that of the swelling, and to the degree of hardnes and thickness with which there may be reason to suppose the tunica vaginalis affected. The cautery which has been most extensively used is the kali purum blended with quicklime, and made into a paste. Acrell made the fuggelion of mixing opium with the cautery, with a view of lessening the pain of the application.

In attempting the radical cure of the hydrocele by this method, it was the design of the surgeon to make the action of the cautery extend through the integuments and cellular substance, and affect the surface of the tunica vaginalis sufficiently to make this membrane inflame. The cautery-paste was generally left on about six or seven hours, and after its removal a pledge was applied, the patient enjoined to keep quiet, and an antiphlogistic regimen directed. The denuded tunica vaginalis did not often burst of itself, or at least not till a considerable time after the detachment of the flax; so that it was generally necessary to make a puncture with a lancet. It was accounted a matter of much importance that the fluid should not be discharged too soon after the application of the cautery, lest the very purpose of the operation should be defeated. About the eighth or tenth day was usually reckoned the best time for making the opening; but the criterion of the proper period was when the patient began to experience a sense of heaviness and heat about the fertom, and the swelling was everywhere painful and inflamed.

When the inflammatory symptoms prevailed, it was customary to apply emollient poultices. These complaints were often exceedingly severe, and attended with pain in the back and abdomen. Bleeding was sometimes required for their alleviation. Surgeons, indeed, found it prudent to prepare their patients for this mode of treatment by diet and medicines, and, after the cautery had been applied, a strict observance of an antiphlogistic plan was deemed generally advisable.

The method, however, was apt to fail when the cautery did not act deeply enough, and the requisite inflammation could not then be excited, without repeating the painful application again.

The treatment of the hydrocele with cautery has now quite fallen into disuse, as being attended with an avoidable destruction of parts, a degree of efficacy not equal to that of an injection, and often creating a painful and ill defined sore, besides being subject to other inconveniences obvious in the foregoing account.

The desire of Mr. Elfe to regulate the cautery with such precision as to burn down to the tunica vaginalis, or just through it, could not, in general, be realized; and the opening could only be completed by employing a lancet, or using the cautery again.

Sene.—The fen was preferred by the celebrated Mr. Pott, as the means of effecting the radical cure of the hydrocele, and, next to the injection, this, perhaps, is to be considered as the most eligible method. The swelling is to be first punctured with a trocar in the ordinary place; an eye probe is next to be introduced through the cannula into the cavity of the hydrocele, and its end pushed to the upper and anterior part of the tunica vaginalis. Just where this extremity of the probe is felt, the surgeon is to make an incision for the passage of the instrument, which will convey with it the fen through the cavity of the tunica vaginalis. But, as the probe is apt to slip away at the moment of cutting upon it, and the skin of silk is liable to rub against the tefficle, when drawn through the cavity of the dilate, the method
HYDROCELE.

The method adopted by Pott is undoubtedly that which deserves imitation. The instruments used by this consummate practitioner, consisted of a trocar, the cannula of which was about a quarter of an inch wide; a feton cannula, which was made of silver, was about five inches long, and was just small enough to pass through the cannula of the trocar; and lastly, a probe six inches and a half in length, furnished at one end with a fine filed trocar-point, and, at the other, with an eye which served to carry the feton. The feton was composed of as much white fewing thread as would fill the cannula, and yet pass through it with facility. The operation was performed in the following way. The tumour was punctured in the common manner with a trocar, and the fluid discharged. The end of the feton cannula was then introduced, through the cannula of the trocar, to the upper and fore-part of the cavity of the tunica vaginalis, and there pressed against the integuments, so as to be externally perceptible. The needle, provided with the feton, was next conveyed through the feton cannula, and pushed from within outwards through that part of the ferorum, with which the end of the tube was in contact. The skein of thread was thus drawn through the cavity of the hydroceles, and both the cannula, having fulfilled their office, were taken away.

The operation occupied but a short time, and was productive of no fever pain. The patient was generally put to bed immediately afterwards, and took about twenty, or five and twenty drops of the tinctura thebaica. On the third day the ferorum was usually affected with swelling and inflammation, symptoms which were soon appeased by means of a bag-traps, emollient poultices, clysters, and a low regimen. The inflammation commonly subsided about the tenth day. From this time, the feton was lefled every day by withdrawing some of the thread, and the discharge of matter from the openings was generally incon siderable. Pott believed, that, in this method, the tunica vaginalis did not suppurate, but was only made to inflame and become adherent to the tefifice. Other surgeons, however, have sometimes found the plan tedious, the feton not becoming loose for more than a fortnight, and large abscesses being occasionally produced, which fiood in need of being opened. Upon the whole, however, the feton may be considered as one of the mildest and fairest modes of cure, and, perhaps, ought to be preferred to all the other plans, excepting one, of which we shall now speak.

Injection.—The method of injecting into the cavity of the tunica vaginalis a stimulating fluid, for the purpose of bringing on an inflammation of this membrane, and thereby a radical cure of the hydroceles, is by no means one of modern invention. Of late years, however, it has been more particularly practised, and the manner in which it has been recommended, and perfected by Sir James Earle, together with its confirmed milinefs and successeis, has almost entirely fet aside all the other modes of cure. According to the statement of the preceding author, even the celebrated Mr. Pott lived to express his approbation of the method, notwithstanding the great partiality which he has evinced in his writings to the feton.

Many different kinds of injection have been employed for the radical cure of the hydroceles. The principal are wine mixed with water; a solution either of two grams of kali purum, or of two grains of cuprum vitriolatum, in an ounce of water; lime-water, either alone, or containing hydrargyrum muriatus; a strong solution of alum, or acetic of lead; brandy diluted with water; an infusion of red roses, or of oak-bark, &c. However, at present, the injection universally employed in this country is composed of port wine and water, in the proportion of two parts of the former to one of the latter ingredient. On the continent, it is not uncommon to use five parts of chart, or Burgundy wine, to one of water.

We learn from Sir James Earle's treatise, that he commonly uses about two-thirds of port wine to one of water. When the parts appear infusible, and no pain at all is produced on introducing the first quantity of the injection, he withdraws the syringe, and increases the proportion of wine. On the other hand, when the complaint is severe, and the parts irritable, he increases the proportion of water, the strength of the injection, in fact, being principally regulated by the degree of pain experienced by the patient. The syringe preferred for this operation is made of elastic gum. The pipe formerly employed by Sir James Earle was furnished with a flat-cock, in order to hinder the injection from making its escape, whenever it was necessary to remove the syringe. Of late years he has used a pipe, one end of which fits the cannula of the trocar, while the other is adapted to receive the neck of the elastic bottle; and instead of a flat-cock, which required a hand to turn it, and was therefore found inconvenient, the pipe is furnished with a valve, which allows the injection to pass into the tunica vaginalis, but not back again. The operation is generally performed as follows: the hydrocele is first tapped with a trocar at its anterior or inferior part, and after all the fluid has been discharged, the cavity of the tunica vaginalis is to be distended to its former dimensions with the visous injection, which, upon an average, is to be kept in the part about five minutes, after which it may be let out through the cannula. The patient commonly feels pain in the groin, and about the kidneys, on the injection being introduced; a circumstance which is rather desirable, as it shows that the stimulus of the fluid is likely to have the wished-for effect of exciting the necessary degree of inflammation.

When the hydrocele is exceedingly large, Sir James Earle recommends practitioners to be at first content with merely discharging the fluid, and to take a future opportunity, when the tumour is smaller, for putting into practice the attempt at a radical cure.

The experience of the same gentleman has proved, that the injection is adequate to the accomplishment of a permanent cure, even though the tunica vaginalis may be indurated and thickened.

The treatment of hydroceles with the visous injection is now generally acknowledged to be the mildest and most certain method, and hence it is universally practiced by all the most eminent surgeons of this country, in preference to the other plans. One great advantage attending it must be immediately obvious:—it does not commonly occasion any suppuration or fore; and it is so efficacious, that many very experienced surgeons have never known an instance of its failing.

It remains for us to give one caution: let every operator be sure that the end of the cannula is in the tunica vaginalis before he ventures to introduce the injection. It has sometimes happened that the cannula has slipped out of the puncture in that membrane, just after the fluid has been discharged, so that its extremity became situated in the cellular substance of the ferorum. Now when the surgeon injected the wine and water, this liquid, instead of passing into the cavity of the hydrocele, was forced into the cellular membrane. Mistakes of this kind have brought on violent attacks of inflammation, abscesses, and sloughing, without there being any chance of a radical cure of the hydrocele. Whenever such an accident happens, it is considered best...
to defer the operation till the fluid of the hydrocele is accumulated again in sufficient quantity.

No objection can be reasonably urged against the method, on account of the preceding accident, which is easily avoidable, and is always imputable either to awkwardness or negligence.

After the operation, the puncture is to be covered with a piece of lint and gauze-plaster, and the scrotum is to be supported in a bag-truss. As soon as the parts begin to inflame and become tense and painful, then an emollient poultice is to be applied to them, care being taken to employ the support, keep the patient on an antiphlogistic regimen, and quiet in bed. If the inflammation should appear to exceed the requisite degree, leeches may be put on the scrotum, the patient gently purged, and even bled in the arm.

Congenital Hydrocele of the Tunica Vaginalis.—The disease is so named when the tunica vaginalis, besides containing a preternatural quantity of fluid, is unloosed above, so as to have an open communication with the cavity of the abdomen. In most cases the fluid, in all probability, is secreted by the peritoneum, and then descends by its weight into the scrotum. This form of the hydrocele has escaped the notice of the generality of surgical writers. The French surgeon Defaut, however, has given a description of it, and we find that he was in the habit of effecting a radical cure by means of a venous injection. The nature of the disease cannot be difficult of discrimination, when the surgeon advertts to the transparency and fluctuation of the tumour, the absence of pain, and the disappearance of the swelling in the recumbent posture, or on prebile being made.

Defaut used to cure the complaint in the following manner. After letting out the fluid with a trocar, he took care to reduce any vesicle which happened to be protruded, and directed a confidential assistant to close the communication between the abdomen and tunica vaginalis by preffiti. The injection was then introduced through the canal into the cavity of the hydrocele. In this way, Defaut not only cured a boy of a hydrocele, but also of a hernia, with which he was afflicted. (Œuvres Chirurgicales de Defaut, par Bichat, tom. ii.)

Hydrocele of the Spermatic Cord.—In this case the fluid is contained in the cellular substance which surrounds the spermatic vessels, and forms what is sometimes named the common sheath of the cord. The water is not diffused in all the cellular membrane of the scrotum. Some writers think that the complaint might, with greater propriety, be called an oedema of the spermatic cord. However this may be, it is certain that this species of hydrocele is the least frequent. In external appearance it is subject to considerable variety, according to the stage in which the disease presents itself. In the early stage, the swelling merely surrounds the lower part of the spermatic cord, and has no connection with the abdominal ring; the upper portion of the cord remaining quite free. The shape of the tumour is generally pyramidal, having a kind of apex above, and a broad base below. The testicle can be quite plainly felt just below the swelling. The tumour is unattended with pain, has a doughy feel, and allows its shape to be altered by prebile. The scrotum retains its natural corrugated appearance, being only somewhat more full and distended on the affected side than the other. In a more advanced stage, the swelling undergoes two alterations; it ascends up to the abdominal ring, so that the upper portion of the cord can no longer be felt; and it descends so far down by the side of the testicle, that this gland is likewise completely concealed. In the extreme stage of the disease, not only the cellular substance which surrounds the spermatic cord in the scrotum is distended with water, but even that which forms the intumescence of the spermatic vessels in their course from the inner to the outer opening of the abdominal ring.

The first stage of the hydrocele of the spermatic cord may easily be distinguished from all other tumours of the scrotum, for there are none which bear so much resemblance to it as to be readily mistaken. But in the very advanced period of the disease, the swelling has much of the appearance of an omental hernia. It has the same soft flabby feel; it passes up into the abdominal ring; and the latter opening is wide and dilated. When the patient has been long in a standing posture, the water descends from the cellular substance which surrounds the spermatic vessels within the ring, and paffes into the cellular membrane, with which they are involved below this aperture; consequently, the external swelling undergoes an increase of size. On the other hand, when the patient lies down for a time, the tumour diminishes. It may also be relieved by external prebile, and even newly pushed within the ring. Likewise, when the patient coughs, or holds his breath, the tumour swells and becomes larger. Such symptoms correspond with those of an omental hernia. The two diseases, however, may, with a little attention, be easily discriminated from one another. By advertting to the early stage of the disease, and recollecting that the swelling first made its appearance at the lower part of the spermatic cord, had then no connection with the ring, and afterwards gradually ascended into this opening, the surgeon may know with certainty that the case cannot possibly be an omental rupture. A careful examination of the swelling will also discover the difference. An epispole communicates the feel of several lumps or masses, and is softer in some places than others. On the contrary, the hydrocele of the spermatic cord has every where a smooth uniform feel. Its shape also undergoes alterations according to posture. When the patient observes an horizontal position, and the scrotum does not hang down, the hydrocele becomes oblong, equally thick, and cylindrical. But when the patient continues in a standing posture, and the scrotum is unsupported, the swelling becomes pyramidal, that is to say, broad below and thin above. Its shape may be altered by making prebile on it for a little while. When the lower part is thus prebile it becomes thin, while the upper portion increases in thickness, and vice versa. Although an omental hernia alters in fize, it undergoes no change of shape, at least none that is so plain and durable. When the horizontal posture or external prebile is long continued, the hydrocele of the spermatic cord, like the epispole, becomes smaller, or even appears to pafs entirely within the abdominal ring. Like this hernia, also, it seems to descend again, when the patient continues erect, or the prebile is removed; but still a difference is observabie in the modes in which the two diseases return. For on applying two fingers to the abdominal ring, at the period when the hydrocele is ascending or descending, nothing can be felt to pafs up or down; but if the case be an epispole, the vifcera can be distinctly felt to pafs into, or out of, the abdominal ring. The descent and reduction of an omental rupture are moreover observed to happen more quickly than the afoent and falling down of the fluid of the hydrocele. When the latter tumour is large, the patient sufferers shooting pains in the loins, at the period of urging the fluid upwards by prebile.

If the disease has made considerable progress, a fluctuation may be distinguished in the swelling, upon laying one hand upon its upper part and the other below, and making prebile with the first downwards, and with the second upwards, in an alternate manner. The abdomen, in the vicinity
HYDROCELE.

Wality of the ring, is alleged to appear sometimes preternaturally prominent, on pressing the fluid upwards.

Lastly, it deserves attention, that, in the hydrocele of the cord, no complaints of the scrotum and ball prevail, as they usually do in cases of epispastocele.

The hydrocele of the spermatic cord is generally a local disease, which proceeds from causes altogether local. Sometimes it arises from wearing an ill made truss. Children are occasionally born with it. (Delatour Journal de Medecine, t. 32.) In certain instances it appears to originate from colliuvial. Frequently it is the consequence of a general dropical affection of the sytem.

Should the disease depend upon internal causes, it is the business of the surgeon to endeavour to remove them. When it arises from local causes, a surgical operation is commonly necessary for its cure, differenters very seldom being found effectual. It is to be observed, however, that when this kind of hydrocele is small, it is hardly an object of surgery; the pain or inconvenience which it produces being so little, that few people would choose to submit to an operation to get rid of it; and (as Pott says) it is very seldom radically curable without one. But when the hydrocele is large, or affects the membrane within the abdominal ring as well as without, it becomes an apparent deformity, is very inconvenient both from size and weight, and the only method of cure which it admits is far from being void of hazard.

Authors describe two operations for the relief of this disease, one is called palliative, and consists in making a few punctures with a lancet in the tumour; the other is named radical, and is executed by making an extensive incision into the swelling.

The great majority of patients are content with the relief derived from the employment of a suppository; and, except in bad cases, an operation seems scarcely advisable.

Encysted Hydrocele of the Spermatic Cord.—The fluid is sometimes observed to be contained in a preternatural cyst formed in the cellular membrane, and resembling such as commonly compose the investment of encysted tumours. This species of hydrocele is most met with in children and young subjects; and not often in adults and old persons.

The swelling is most frequently situated about the middle of the spermatic cord, and is more or less of an oval shape. In some cases it lies close to the cord; in others it is so distant from this part, that the finger may be put between them. Below the tumour is the inferior portion of the spermatic cord, together with the testicle; while above, the upper part of the cord can be plainly felt to be quite free, so that the swelling manifestly has no connection with the abdominal ring. But there are examples in which the disease acquires such magnitude, that it mounts upwards as far as the ring, and descends down to the bottom of the scrotum. In this circumstance the care may not fail but resemble the hydrocele of the tunica vaginalis. The testicle, however, can always be distinctly felt on the outside of the swelling, a fact which immediately makes an experienced surgeon acquainted with the nature of the disease. A mistake would not always be impossible, and, with no serious ill consequences, the treatment of both tumours being similar. It may be remarked, likewise, that the swelling is completely circumferent, has a very even surface, and is entirely free from pain. A distinct fluctuation cannot often be felt.

In young subjects, the tumour may frequently be diffused by external means; but in ordinary cases a surgical operation is indispensable for the cure of the disease, and is of two kinds: one palliative, the other radical. The first consists in merely discharging the fluid with a lancet or trochar. Care must be taken to avoid injuring the spermatic cord. Here a lancet is mostly preferred to a trocar. In children, tapping the tumour is often productive of a radical cure. The cyst is frequently found filled with a fluid of so viscid a quality, that it will not pass through the cannula of a trocar.

The radical operation, formerly practised, was to lay open the swelling its whole length, and cut away as much of the cyst as could be accomplished, without risk of wounding the spermatic vessels. The wound was afterwards dressed with digestive applications. Modern experience proves, however, that this case can be radically cured with the port wine injection, just like the hydrocele of the tunica vaginalis, if the method is free from all severity and danger, it certainly deserves to be recommended. Sir James Earle assures us, that he has successfully treated the disease in this way.

In certain cases, two or three separate cysts, filled with fluid, are met with in the cellular membrane of the spermatic cord or scrotum. While small, they can easily be distinguished from each other; but when they have acquired a considerable size they lie so close together, that they seem like one single uniform swelling. Turrows, however, may frequently be felt between them, and some information may be obtained from a recollection of the early stage of the disease. But in operating, the nature of the case cannot fail to shew itself, it being impossible to discharge all the fluid, unless an opening be made into each of the cysts. Every operator should use the utmost care not to injure the testicle and spermatic cord, as these parts have no fixed situation with respect to the tumours. The place of the testicle may, indeed, be often ascertained beforehand, by the peculiar pain which is occasioned by pressing it.

Encysted hydroceles have occasionally been remarked in women. They are mostly situated in the vicinity of the groin (Journal de Medicine, t. 82.) or else in the labia. Authors advise us to treat them just like other encysted hydroceles. We see no reason why they should not be extirpated in the manner of common encysted tumours.

Hydrocele of Hernial Sac.—Hernial sacs occasionally contain, besides the protruded viscera, a quantity of fluid, which is frequently so copious, that the bowels cannot be felt, the water alone being perceptible, and the case apt to be mistaken for a common hydrocele of the tunica vaginalis. But the diagnosis can be attended with no difficulty, when the visera admit of being reduced. However, in some cases, the protruded parts are adherent to the neck of the sac, and as the method is free from all degree capable of reduction, they prevent the fluid from passing up into the cavity of the abdomen. In this circumstance, the surgeon may easily fall into error, though a correct judgment can always be formed by paying a little attention. In the early state the disease has commonly been nothing more than an ordinary intestinal or omental hernia. The recollection of this fact throws much light on the nature of the case. The swelling at its commencement is always connected with the abdominal ring. The testicle can be felt at the under and lower part of the tumour. The patient is likewise afflicted with the usual symptoms of an enterocoe or epispastocele. Were any of the operations, employed for the cure of common hydroceles, erroneously practised in the preceding case, excepting that of merely letting out the fluid, the consequences would be highly perilous, and, in all probability, fatal.

When a hernia has been reduced, and the defect of the bowel again effectually hindered by the gradual closure of the neck of the sac, a collection of fluid sometimes takes place in the cavity of the latter part. We have already de-
scribed the congenital hydrocele, where water collects in the tunica vaginalis, and the sac has an open communication with the abdomen. We have further recorded the success with which Daffiel freed a lad not only of such a hydrocele, but also of a hernia, by the employment of an injection. Certainly, the hydrocele of a hernial sac, when the neck of the latter part is closed, may be safely treated just like an ordinary hydrocele. But should the sac communicate with the abdomen, or contain any protruded parts, such treatment would be rash and almost certainly fatal.

HYDROCELODES ISCHIAH, in Surgery, a retention of urine, produced by a rupture of the urethra. The term is derived from ischias, water, and $\tau\omicron\alpha\varsigma\alpha\omicron\nu$, attended with swelling.

HYDROCEPHALUS, in Medicine, from $\iota\omicron\nu\epsilon\omicron\rho\omicron\omicron$ and $\zeta\omicron\nu\delta\omicron\nu$; the head, signifies strictly dropsy, or water, in the head.

For the knowledge that we possess, relative to the nature and characteristic symptoms of effusion of water within the cranium, we are indebted almost entirely to modern observation. Hippocrates, Aëtius, Celsus, and some other ancient physicians, speak of the presence of water between the cranium and the surface of the brain, and of an external hydrocelephalus, or dropsy of the teguments of the head; but the writers of the 16th century first mention the occurrence of water in the ventricles of the brain itself. (See Mercurialis, Opuscula Aurea, lib. de Morb. puerorum.) After this occurrence had been observed by a number of writers, and had even been mentioned by the celebrated Boerhaave, the symptoms, by which it might be distinguished from other diseases of the brain, remained still unknown. The effusion was briefly and inaccurately described in the Memoirs of the Academy of Sciences at Paris, for the year 1718, by M. Petit; but it was not until the publication of a posthumous essay of Dr. Whytt, professor of medicine at Edinburgh, in 1768, that a well-connected history of the symptoms accompanying the effusion of water into the ventricles of the brain was clearly made out, or that hydrocelephalus was known as a distinct disease. Immediately after this publication, Dr. Fothergill, whose sagacity had already detected most of the peculiarities belonging to the disease, read a paper on the subject to a medical society in London, which was published in 1772 (see Med. Observ. and Inquiries, vol. iv. art. 3.), since which period the disease has been well known to medical practitioners.

Before the appearance of Dr. Whytt's Essay, the term hydrocelephalus had been almost entirely confined to a chronic affection, analogous in its causes and progres to other forms of dropsy in the human body. This disorder, commencing soon after birth, before the futures of the skull are united, proceeds very slowly, continuing even for years, until the head becomes enormously large, without producing any very extraordinary symptoms. After death, which is usually preceded by convulsions, the brain is found so exceedingly diffused by water within the ventricles, as to be rendered extremely thin; or, on the other hand, so much oppressed by the water, collected between it and the skull, as to assume rather the appearance of a small gland than that of a brain. This form of the disease, or the chronic hydrocelephalus, we have described under the article Dropsy in the Head. The variety of the disease, to which our attention is at present directed, differs altogether from the one just mentioned; and, being accompanied by febrile symptoms, and generally of short duration, has been distinguished by the appellation of acute hydrocelephalus, or

HYDROCEPHALUS ACUTUS. This name was first appropriated to the disease in question by Dr. Charles William Quin, of Dublin, in his inaugural dissertation, published at Edinburgh in the year 1779. He pointed out the febrile, or rather inflammatory nature of the affection of the brain, in the commencement of the complaint, of which the effusion of water appeared to be a consequence, and by which the disease was distinguished from the ordinary dropsical effusions. Dr. Cullen, being convinced of the accuracy of this statement when he republished his "Neuologia Methodica," in 1780, removed the acute hydrocelephalus, from the dropsies to the apoplexies, with the new appellation of apoplexia hydrocelephalus, and retained only the chronic form as one of the genera of dropsies, with the old name of hydrocelephalus. Dr. Raff, of Philadelphia, having taken the same view of the disease with Dr. Quin, and, deeming it inflammatory in the commencement, called it phrenicula, from its being a distinctive species or plate of phrenitis, or inflammation of the brain. See his Med. Inquiries and Observations, vol. ii. p. 215. Philad. 1793.

Physicians have acknowledged the extreme difficulty of detailing a distinct history of the symptoms of hydrocelephalus, which shall be exemplified in every case; and they have, especially, differed in describing the appearance which the disease assumes in its commencement, and the length of time which it usually occupies in its progress. The truth is, we believe, that each writer has been what he has described; for that the malady actually puts on a considerable variety of character, both in respect to its phenomena and duration. The latest writer on the subject, Dr. Heyes, now of Dublin, has described three different modes in which it has made its attack in different instances which have fallen under his observation (see his Essays on the Diseases of Children, Edinb. III. Edinburgh, 1805.) and a similar division of the varieties of the disease has also been made by the professor Kuhn of Leipzig. (See Edinburgh Med. and Surg. Journal, vol. iii. p. 13.) These are, 1st, when the symptoms come on slowly and gradually; 2d, when the attack is sudden and the progress more rapid; and 3d, when the disease ensues upon some previous indisposition. The first of these Dr. Kuhn terms the nervous, and the second, inflammatory hydrocelephalus; the third he mentions only as a sequela of scarlet fever. These varieties of the symptoms, however, only mark the attack of the disease; for in the latter stages there is little diversity in the appearances.

In the first, or gradual mode of attack, before any characteristic signs of the disease appear, the child for some days, or even weeks, has complained of pain in his head or belly, while at the former time he has been slightly feverish, dull, and irritable; he has been listless, without appetite, or perhaps with an increased appetite, and with some disorder in the functions of the abdominal viscera. These complaints rise gradually; but are seldom alarming; and the child's friends are not awakened to a sense of his danger, until, advancing a step further, the disorder begins to show itself more distinctly. The dulness is accompanied with pains in the head, which is also connected, upon getting up in the morning perhaps, or after he has begun to stir about, with vomiting. Yet even this symptom is often disregarded, until the second or third day of its recurrence, and the disease has made considerable progress, before the ill effects of the patient is suspected to arise from a disordered condition of the brain.

When the attention is more particularly excited by these symptoms, the head aches, which is chiefly in the forehead, or sometimes in the crown, will be found to return at shorter intervals. The child often afflictingly complains of his head. He sighs frequently, is dull, his head requires to be supported; he complains of weariness in his eyes; the pupils are sometimes unusually contracted, and he has an averse
to light; his tongue is white, and his belly generally colicive; the stools are first clayey; as the diæase advances they become of a gelatinous consistence, of a dark green colour, sometimes as dark as tar, and of a sickly smell. The pulse becomes quick; and at particular times of the day these symptoms are attended with febrile heat and irritability, and the child complains not only of head-ache, but of pains in different parts of the body, sometimes extremely acute. At one time he complains of pains in his limbs, at another of pains in his head, or in the nape of the neck, very often in his bowels; and before the anxiety of his friends can make any preparationsto relieve him, the pain is gone, or fled to some other part; at another time he lies on his mother's knee, re tires, and whining, as from dull rheumatic pain. These disorders necessarily impair the child's strength, and in the course of ten days or a fortnight his appearance is considerably altered; he is peevish and feeble.

In the second form of the attack, Dr. Cheyne observes, the diæase runs a more rapid course. After the child has been drooping for a short time, which, although it sometimes escapes observation, is generally recollected, there is a sudden change to a fever, attended even from the first with a great degree of heat and irritation, with frequent but short and irregular respi rations, and at first with a pulse of fecretion, tender ness all over the abdomen, and increased sensibility, with often innumerable passages, most of which are difficult immediately to distinguish hydrocephalus from fever, and this is the form of the complaint in which there is the greatest resemblance between the two diæases; but we are led to suspect some deeply seated evil, from the frantic ecstasies, and complaints of the head and belly, alternating with stupor, or rather sighs; and we are struck with the irritability of the stomach, in a degree beyond what we find in fevers of this country, retching and vomiting being often brought on by a change of posture, certainly by every attempt to sit up in bed, and with the disordered state of the bowels which attends this irritability of the stomach; and when at any time the child has a little refpite from the violence of these symptoms, we find our suspicions confirmed by his look; for, in this diæase, when the features do not express pain or terror, there is not un frequently an expression, which it has in common with some other diæases of the brain, of dejection, bordering upon infensibility, which is quite insupportable to those who are interested in the patient's recovery.

In the third mode of attack, when hydrocephalus arises after an imperfect state of health, as where there had been a febrile action which has abated, or where the child has had some epidemic diæase formerly (perhaps many months before), from which he has not perfectly recovered, or regained found health, the attack is sometimes made with all the violence distinguishing the second form just described. When again the attack comes on as the sequel of an acute diæase, as fever, hooping-cough, perhaps diphtheria, or during some actually existing febrile diæase, the child almost imperceptibly slips into hydrocephalus; there are fearfully any of the acute symptoms; and the palpitations or convulsions are the first indications of the new disorder.

In whatever mode the disorder commences, it is marked in what has been called, by Dr. Whytt, the first phase by a febrile condition, varying much in degree and regularity; the sleep becomes imperfect and apparently uneasy, the little patient often grinding his teeth, picking his nose, and staring with a scream, as if he were terrified. There is great fluctuation in the feverishness: at one time the pulse is quick and throbbing; the heat of the body is increased; the skin parched; there is a deep blush on the face, more especially on one cheek; and the breathing is rapid, laboured, and quick; at another time the blood circulates more equally; the skin is of a natural warmth, or moist with temporary perspiration; the countenance is pale; and the respiration is loft that it cannot be heard. There is also great fluctuation in the state of the other functions. Sometimes the state of the stomach appears to be nearly natural; at other times the heavy smelling breath, that has been suppos'd by Dr. Whytt to be peculiar to this diæase, the total absence of appetite, and constant vomiting, even for days, the stomach to be in the greatest disorder. The bowels are never regular; they are generally slow, requiring cathartic medicines, and now and then a constant and severe bilious purging attends the vomiting. The urine is sometimes withheld for 24 or 36 hours; occasionally a frequent desire to pass it has been observed. And not only are the vital and natural functions irregular; we find the same extremes in the animal functions; to this, indeed, the diæases of the brain owe much of their interesting character. The senses and judgment are often perfect and entire, sometimes morbidly acute; in general the retina is painfully sensible to light, and the child is sometimes unpleasantly affected by light sounds; on the contrary, sometimes, even in the early days of the diæase, the mind is subdued, and there is the greatest dulness of apprehension.

It generally happens, but by no means with the certainty which the description of Dr. Whytt would lead the student to expect, that after the first or sebile symptoms have continued an indefinite time, from a few days to a fortnight or more, a remarkable change takes place in the diæase, especially in the condition of the pulse, by which the commencement of the second phase, according to Dr. Whytt and others, is marked. The pulsations become slow, even slower than in health, and at the same time unequal and irregular, both as to strength and the intervals between the strokes; but, as Dr. Cheyne remarks, they are easily doubled by the heart exertion. With the flow of the pulse, a greater degree of dulness and torpor comes on; the pain of the head seems to abate, or at least the patient becomes apparently less sensible of it; and as this phase advances, he grows drowsy and lethargic, yet moves heavily, without being able to tell what distresses him; and often flirts and cries in a wild manner, as if from momentary attacks of acute pain. The pupils are observed to be dilated, and a want of sentience between the two eyes, attended with imperfect, and not unfrequently double vision, takes place. As the diæase proceeds, the frowning and dilatation of the pupil increase; the patient lies with one or both eyes half closed, which, when minutely examined, are often found to be completely insensible to light; and they now lose their vivacity in consequence of a filmy covering of the cornea. The fixkews ceases, and whatever food or medicine is offered, is usuallly swallowed with apparent voracity; the bowels generally remaining obliterately colicive.

These symptoms are soon succeeded by others, which mark the third phase, and announce the approach of death within five or six days, or sometimes within a much shorter period. The pulse now becomes equal and regular, and rises to a rapidity greater than ever; which continues to increase while life remains. There is no diæase, we believe, in which the pulsations become so frequent, and yet continue distinctly measurable, as in the closing scene of hydrocephalus. Dr. Whytt says, that no patient dies of this diæase, while his pulse remains under 150 beats in the minute; in one case it counted 210 in the minute on the day of death. We have distinctly enumerated 190 beats under the same circumstances.

A comatose.
HYDROCEPHALUS.

A comatose state now comes on. The patient lies with a frequent hectic flush on his cheek, alternating with a deadly paleness; drawing a long sigh at intervals; often grinding his teeth; incoherent, or in a state of complete insensibility; perhaps picking about or fawing the air with one hand, while the opposite side is pallid; with a burning fever on his skin, or sweat forced from every pore; and all these symptoms alternating with, and at last finished by, apoplectic breathing, and convulsions.

The whole course of the symptoms, as well as the changes in the state of the pulse, which occur in each of the three stages, constitutes a very remarkable peculiarity in this disease, and gives a character to each stage. The first has been called the stage of increased sensibility, or inflammatory irritation: the second, that of decreased sensibility, or torpor; and the third, the paralytic or convulsive stage. In the first, every stimulus produces an inordinate effect: there is great avarice to light and to sounds; watching, sickness, pain, and quickened pulse. In the second stage, the child is not easily roufed, his pupil is dilated, and does not contract on the approach of light, his pulse is slow, he is lethargic, with often an obstinately coitive belly. In the third stage, which may, perhaps, be considered as a continuation of the second, there is quixting, rolling of the head, delirium, fluoror, convulsions, with a rapid thready pulse.

Physicians have represented the duration of the disease differently: Dr. Whytt supposed it to extend to four, five, or six weeks, from the date of the first symptom; while Dr. Fothergill commonly found it to terminate in three weeks. On the whole, experience seems to have corroborated the observation of Dr. Fothergill. But, like every other disease, of the brain, hydrocephalus is uncertain in its duration, especially when the pulse has become slow, or the stage of torpor has arrived. Sometimes, in the course of two or three days from this change, the child shall be carried off; while, in other cases, even the last stage continues days after day, for upwards of a week, when, at every visit, the observer would conceive that the patient had only a few hours to live. In cases of the second, or acute mode of attack, and also in the third, the whole disease sometimes runs its course in a few days; while, in the first mode, from the great length of the first stage, it has been observed to last many weeks. Dr. Quin states, apparently on conjecture, that the disease may be expected to be more rapid in its course, in adult persons, than in young children. But our observation accords with that of Dr. Cheyne and others, in dilating the contrary. In a boy of twelve years old, we once saw the disease run on, in a very gradual course, to the length of eight weeks, and then terminate fatally.

Nor is there less variety in the symptoms and progress of the disease, than in its duration; infomuch that Dr. Quin has called it a "truly Protean disease," and Dr. Rush accords in the judiciousness of the appellation. Cases have terminated fatally, in which some one or more of the characteristic symptoms have not appeared, and sometimes when "no one symptom afforded any suspicion of the real cause of death," which was ascertained by dilatation. (See Dr. Quin's Essay, p. 45.) The same author mentions another case, which terminated fatally in seven days, and dilatation determined the nature of it; "yet the usual variations of the pulse in the several stages did not take place; the pupils were not dilated until the last day of the child's life; he never once vomited, never expressed a dislike to light, and the head-ache, though constant, was not violent." Dr. Rush observes, "I have not found the dilated and intense pupil, the puking, the delirium, or the iritability, to attend universally in this disease. I saw one case in which the appetite was unimpaired from the first to the last stage of the disorder." (Med. Inq. and Obs. vol. ii. p. 259.) On the contrary, we lately saw a case, in which the chief symptom of dilatation, for the first four or five days, was a constant faintness in the face, which rejected almost every thing as soon as swallowed while the head remained apparently free from uneasiness. Other cases are mentioned by Dr. Ruth, in which no head-ache occurred during the course of the disorder; in which no preternatural flow of tears, or intermission was ever perceived in the pulse; and in which no dilatation of the pupil, squinting, sickness, or loss of appetite had attended; and others, in which an uncommon sensibility of hearing, palsy of one side, and the symptom of hydrophobia, had respectively occurred. Dr. Whytt also mentions an irregularity in the state of the pupil. "Three or four days before the death of a boy of five years old," he says, "I was surprized to find the pupils, which had been much dilated before, no larger than natural. At first I flattered myself that the disease had taken some favourable turn; but was soon undeceived: for, upon giving the child a spoonful of weak cinnamon water, with some drops of the common stimulant, and water, the pupils became as wide as they had been the day before. In less than half an hour after they contracted again; but immediately dilated upon holding the patient by the arm of his mother another jell of fat amnion made to his nose. I have from time to time observed the same interchanges in the pupils of a boy of four years old, on the third day before he died. In this case the pupils not only were enlarged, by giving him a spoonful of wine, or holding volatile spirits to his nose, but also by so small a stimulus as lifting up his eyelids, which had lost all their motion, and had fallen so far down as to cover near the half of the eye." Observations on Dropping in the Brain, Whytt's Works, p. 733.

Diffusion.—The circumstance which was first noticed, on examining the head by dilatation, in patients who had died of this disease, was the constant occurrence of a limpid watery fluid, diffusing the ventricles of the brain, and amounting in different instances to the quantity of from two to six ounces. In some cases, only one of the lateral ventricles has been found thus diffused. A small quantity of fluid is also commonly found between the membranes surrounding the brain, especially under the tunicæ arachnoideæ, both above and at the base of the brain. The water, collected from the ventricles in hydrocephalus, does not coagulate by heat; in which respect it differs from the serum of the blood, from the water that is found in the pericardium, and from that which is taken from the abdomen, by tapping, in dropy.

But in addition to this effusion of water, later authors have observed, in many instances, the marks of congestion in the blood-vessels of the brain, and of different degrees of inflammatory action. Dr. Cheyne remarks, "upon dilatation, we generally find within the cranium, the veins, particularly those of the membranes on the surface of the brain, and lining of the ventricles, gorged with blood; sometimes considerable adhesion between and thickening of the membranes, and minute and florid vessels upon the pia mater." (Loc. cit. p. 511.) And Dr. Quin las related several cases, "where the quantity of fluid found in the ventricles was very considerable; but at the same time, there were signs so visible of an increased flow of blood to the brain, that in all of them the vessels were remarkably turgid; in most of them a degree of inflammation had taken place, as appeared at the time of dilatation, either by preternatural dilatation of the membranes, or by a partial opacity and increased thickness of them, together with patches of inflammatory crust, very similar to those which are found on the abdomi
HEMORRHAGIC FLATULENCE.

Mortal ulcers of persons whose death has been the consequence of interitis; or on the lungs and pleura of those who have fome under pulmonary inflammation. P. 51.

In investigating the fents of difeafe by defcription, physicians are too apt to confine their examinations to that part of the body, in which the moft prominent symptoms of derangement had occurred during life; by which practice a very imperfect knowledge of the morbid changes is often acquired. This error is too frequently committed in fpect to hydrocephalus, when the contents of the cranium alone are examined; for it appears that the vifera of the abdomen often suffer in this difeafe. "In the abdomen," says Dr. Cheyne, "I have found the intestinal inflamed, and conflidted from fap, an effential and the furface of the liver of a bright red colour, abounding in minute veifels; and fometimes excedingly adhefive to the peritoneum. In feveral difeafes, I have found the furface of the liver studded with small white tubercles, not larger than a grain of miflal. The glands of the mofentary are often difeased, &c. (P. 51.) And, in another place, the fame writer remarks, "upon difeafion of hydrocephalic children, I have found in the liver the remains of great inflammatory action, and alfo proofs that undue irritation had existed in the alimentary canal." P. 46.

Caufe of Hydrocephalus. This fubjeet remains in some degree of obfcurity; more especially in what regards the exciting caufes. A predefition to the difeafe is pretty obvioufly found in that peculiarity of confitution which is allied to fetafis, and which is characterized by a frame of body that is rather delicate and irritable, and often beauiful—and by acutenefs of thefent and vivienefs of difpofition—the body being fair and well coloured, the eyes blue, and the hair light. This predefition is often hereditary, and attached to particular families. Dr. Cheyne attended two families, in one of which four children, in the other three, died of this difeafe; and he had "heard of an unfortunate family who loft feven children of hydrocephalus." We are acquainted with one, in which seven children perifhed from this malady, when they arrived at a certain age, apparently of furmous confitution.

Sauvages has a fimilar obfervation. "Novi familiam," he fays "cujus infantes circa fextum aetas annos omnium pereire ex horro, fetafis hic effeundi effunat præbente." (See his Nefol. Method. clafs. iv. gen. xii. 5. Convinh ab Hydrocephalo: —169, gen. xvii. 14. Eaciamplia ab Hydrocephalo.) Dr. Percival flates, "that of twenty-two caufes of which he kept notes, eleven were certainly ftrumental children, and four were probably fo." (Med. Facts and Obferv. vol. i. p. 139.) Hydrocephalus is more particularly a difeafe of childhood, occurring moft frequently in the middle years, between weaning and puberty. Occafionally, however, it is seen at every period of life, with the exception, perhaps, of old age. A fale of imperfect convallance from febrile fever, meafles, small-pox, whooping cough, and other acute difeafes, appears to generate a predefition to hydrocephalus. Many caufes of hydrocephalus occur, of which no exciting caufe can be traced, fometimes, indeed, little accidents, as falls and blows, are recollected, when the difeafe has made its appearance, which had occurred feveral weeks or months before, and had excited little attention at the time. Whether these accidents were actually the caufes of the difeafe, which thus enfued, after a long interval of health, is certainly a matter of doubt. Dr. Cheyne observes, that, in upwards of a hundred caufes which he had attended, he had only met with one, in which external violence could be confidered as the origin of the difeafe, and that in an indirect manner. This child had, at the fame time, a fever and obflinate catarrh; which he deemed more likely to impair the general health, and thus to predispose to hydrocephalus. He adds, that he has repeatedly seen symptoms of fetafis following a fever accidcn, which may thus immediately induce hydrocephalus, by deranging the general health, and calling into action what, from a good and fortunate management, had hitherto been latent.

It would seem, however, that any circumfance which can produce a flate of general debility, but especially any caufe exciting an active feverish flate, of the inflamatory kind, in children predisposed to the difeafe, will call it into action. Hence the irritation of teething, and of worms in the alimentary canal, fpecially if attended with convullions; fudden exposure to cold, fever's rheumatic; pulmonary conftitution; colic, and other difeafes, have been mentioned among the caufes of hydrocephalus. (See Ruth, Med. Inquiries, vol. i. p. 211, et seq. and the references there given.) Some other caufes have been alleged; fuch as a nervous, or spontaneous metafis: of erupfions, fpecially of the fcald head; the healing of old ulcers, the exfution of cutaneous difcharges; a ferous collywie of the blood; rup-
the ventricles; "but the brain was so turgid, that when the bones were sawed fairly round, the section was thrut up half an inch by the fudden and forcible protrusion of the cerebrum; not only the veins of the pia mater were loaded with blood in a very remarkable degree; the medullary substance of the brain was finely dotted with numerous red points, and the cortical subflance streaked with pencil of red parallel lines." In the other infatice, "no effusion was disco-
cered in the ventricles" after death. It was an extreme case of the acute hydrocephalus, where the excitability was sud-
linly exhausted by the violence of the attack. "When, as in this cafe, Dr. Cheyne adds, the child dies early in the disease, with every symptom of accelerated arterial action, but before the subfequent convulsion has exifted for any length of time, the dilatation will never afford much effufion. When, on the contrary, the patient long survives the fiew puls; and when, from the continuance of the dilatation, we have reafon to think that the conftitution has exifted for a con-
fiderable time; then we find a large effufion. In fuch cafes I have defcrived, within the head, little appearance of arte-
ria! action, as marked by the tifue of minute and florid veffels: this flage of the dilatation was over; yet the effects of infamiation abundantly appeared in the thickened and greater adhesion of the membranes; in the great conftitution; and indeed, from the pain, fuffufion of the eye, &c. we cannot doubt that it exifts to the laft." (Cheyne, p. 63.)

Dr. Quin details feveral cafes, in which, together with con-
fiderable effufion of water, the veffels were found extremely turgid, and the previous exiflence of a degree of infamiation was demonstrated "by preternatural adhefions of the meninges, or by a partial opacity and increased thickness of them, with patches of infamatory crudr," &c.

On the other hand, feveral cafes are on record, in which quantities of effufed fluid have been found, on dilatation, in the ventricles, when no complaint of pain in the head, or fymptom denoting an opprefled brain, had exifled before death. Manifacal patients, in whose ventricles many ounces of fuid have been found, have died without evincing any hydrocephalic fymptoms. And, in fact, there is scarcely any organic dilatation of the brain which is not accompanied by effufion.

Thafs being admitted, we think it was unnecessary to argue the point taken up by Dr. Cheyne, againft Dr. Quin and Dr. Ruff, viz. whether "the morbid arterial action" in the brain amounts to such a degree of infamiation as entitles it to be compared with *phrenitis*, or to be called *phrenicula*; or whether we must be content to fay, with Dr. Cheyne, that it appears "to confift of a dilatated action of a pecuflar kind." P. 82.

This view of the dilatation, however, although doubtlefs correct as far as it goes, does not embrace the whole of phenomena. It has often been obferved that a train of fymptoms, familiar to thofe of hydrocephalus, has arifen from the fympathy which fubfists between the brain and other organs, efpecially the alimentary canal, the liver, and the urinary organs. (For infafions of fympathy with the lail mentioned organs, fee Sauvages, chas vi. gen. xxix. 4. Carnis ifebrifos, and the references there given: also Med. Facts and Obf. vol. i. art. 1.) It is chiefly, however, as Dr. Cheyne obferves, from a morbid state of the liver and alimentary canal, that we find the hydrocephalic fymptoms by afocation to arise. Every practitioner of obfervation has probably been occa-
ationally surprifed by the recovery of children under many of the fymptoms of hydrocephalus, while purgative medicines, efpecially the mercurial clafs, were adminiftered. Dr. Willan states, that the hydrocephalus of Dr. Quin, marked by the prudence of inflammatory irritation in the head, as above decribed, "should be diftinguifhed from the fym-
tomatie hydrocephalus, which often takes place, with very similar fymptoms, after the crifis of malignant fever; during the *bclitica infantifia*, and in some other acute dilatations of children, particularly the febrile flate produced by dietition, worms, and diforders of the bowels and mefentery. Cafes of this kind are ufually removed, within a week or two, by the ufe of calomel or other active purgatives, and bliflers." Reports on the Difefes in London, p. 270.

Now we think this statement much too general. It is certain that thefe irritations and morbid conditions of the bowels are common concomitants of the ordinary and fatal dilatation of hydrocephalus. In his description of the fecond stage of the dilatation, Dr. Witty mentions the dilatation of worms, or of some fubflance like worms in a dilated flate, as a "frequent" occurrence (Works, p. 732.) and we have more than once been a *luminous void* under the fame circumstances. The condition of the bowel, when hydroce-
phalus is established, is fo peculiarly morbid, that the doctors practife to speak of "hydrocephalic bowels," as sufficiently intelligible to those who have made any obfervation on the fubjeft. The evacuations appear to fift only of a dark gary bile, mixed with the mucus of the intines. There are many other conformation, too, which tend to prove the connection of the proper hydrocephalus with this morbid condition of the abdominal vifera, and to support the opinion of Dr. Cheyne, Dr. James Curry, and others, that this dilatation is often fairly and incurably established by the fympathy which the brain has with thofe organs." Cheyne, loc. cit. p. 38.

In the firft place it would appear that hydrocephalic fym-
ptoms, arising from fympathy with difordered digestive or-
gans, have fometimes proved fatal, without producing any obvious change of structure in the brain. Mr. Abernethy examined the body of a child, who had unequivocal fymptoms of hydrocephalus, in which the brain was found perfectly healthy, the only dilatation appearing in the bowels. (See his Surgical Observations, part ii. p. 195.) Again, Dr. Hamilton has obferved, that "hydrocephalus often steals slowly on the devoted victim, with fymptoms resembling thofe of marasmus;" whence he thinks it is unreasonable to fuppofe that the marasmus, which is clearly the reful of a morbid flate of the liver and bowels, may occasionally give rise to hydrocephalus. (See his Observations on Purgative Medicines.) Dr. Cheyne advances similar obfervations. "In many cafes," he fays, "previously to the hydrocephalic fymptoms, the chyladopic vifera have been dilatated for many weeks. The appetite has been bad; the bowels colhve, the floors betraying dilatation in the hepatic fyltem; there has been all that want of alab-erity, both of body and mind, so invariably the conquence of the derangement of the biliary fecretion; and in feveral children, previous to the exiflence of any morbid fenfation, the firft symptom of ill health was the los of the healthy colour of the skin. In children predilatated to the dilatation, I have, while removing, by a course of purgative medicines, a vitiated biliary secretion and dilatated state of the bowels, removed also the very fymptoms which had preffented them-

in other children of the fame family, when the attacks of a hydrocephalus, which actually proved fatal, were pre-
vided to have been dilatated. In children, where I did not know of any family predilatation, I have, by the fame means, in many infafions, removed the fymptoms which are always found in the beginning of hydrocephalus." — "The in-
creased arterial action on the surface of the liver, the remains of which I have obferved in my dilatations, to every appearance had been of some standing, and in two or three infafions,
from the extent of the adhesions, it evidently had been of
great intensity. While the disease is forming, there is gene-
rally a defect in the function of the liver: it seems to admit
of only a scanty and imperfect formation of the bile, insuffi-
cient to dilate the intestinal canal, which becomes torpid,
and is sometimes loaded with fetid clay-coloured excrement."
PENDIX TO DR. CHEYNE'S TREATISE. DR. WILLAN MENTIONS THREE CASES OUT OF EIGHT WHICH TERMINATED FAVOURABLY, "TWO RECOVERED ABOUT THE EIGHTEENTH DAY OF THE DISEASE, THE THIRD, AN INFANT, AT THE END OF THE FIFTH WEEK, AFTER HAVING BEEN LONG ABANDONED TO ITS FATE." (REPORTS ON THE DIFF. IN LONDON, P. 269.) THE CHANCE OF CURE IN GENERAL, HOWEVER, IS NEARLY IN THE INVERSE PROPORTION TO THE DURATION OF THE SYMPTOMS.

IT HAS BEEN OBSERVED BY DR. CHEYNE, THAT A GREAT INCREASE OF URINE HAS OFTEN OCCURRED WHEN THE DISEASE HAS TERMINATED IN RECOVERY; AND THAT WHEN THE URINE FLOWS FREELY AFTER GIVING MERCURY, IT MAY BE DEEMED A FAVOURABLE PROGNOSTIC. OCCASIONALLY A COPIOUS DIAPHORESIS, ESPECIALLY FROM THE HEAD, HAS ALSO PRECEDED RECOVERY. IN ONE CASE, AFTER A CHILD HAD BEEN CONSUMED AS IN A HOPELESS FLAT, AND THE PHYSICIANS HAD DISCONTINUED THEIR VISITS, "A PROFUSE SWEAT BROKE OUT ON THE HEAD AND NECK, AND FLOWED SO COPIOUSLY THAT THE PILLOWS HAD TO BE SHIFTED ONE AFTER ANOTHER. FROM THAT MOMENT THE CHILD IS SAID TO HAVE RECOVERED, AND YET LIVES. SEVEN YEARS HAVE ELAPSED SINCE HIS RECOVERY." P. 87. NOTE. SEE ALSO A CASE IN THE EDIN. MED. COMMENT. VOL. X. P. 299, AND DR. QUIN'S TREATISE, P. 73.

OF THE CURSE.—IN A DISEASE WHICH, FROM ITS VERY COMMENCEMENT, IS OF A MOST DANGEROUS TENDENCY, AND WHEN COMPLETLY ESTABLISHED IS COMMONLY FATAL, IT IS OBVIOUS THAT, IN ORDER TO HAVE ANY TOLERABLE CHANCE OF SUCCESS, THE TREATMENT SHOULD BE ENTERED UPON EARLY, IN A DECISIVE MANNER, AND PURSUED WITH FLEETNESS AND VIGOUR. THE PRINCIPAL INDICATIONS OF CURE APPEAR TO BE, FIRST, TO DIMINISH THE INFLAMMATORY ACTIVITY OF THE CIRCULATION IN THE BRAIN; AND, SECONDLY, TO REMOVE ALL TENDENCIES, ESPECIALLY IN THE ALIMENTARY CANAL, AND TO CORRECT THE HEPATIC SYMPTOMS OR CONGESTION, WHICH, BY ORBITAL SYMPATHY, MAY HAVE GIVEN RISE TO, OR MAY HAVE AFFLICTED IN PROLONGING THE DISEASED ACTION IN THE BRAIN.

IN THE VERY EARLY PERIODS OF THE DISEASE, INDEED, OUR FIRST ATTENTION SHOULD BE DIRECTED TO THE STATE OF THE ALIMENTARY CANAL, AND AN ACTIVE CATHARTIC SHOULD BE GIVEN, AND REPEATED ACCORDING TO CIRCUMSTANCES. SHOULD WE ASECERN THAT THE CANAL IS TORPID, AND IMPERFECTLY PERFORMING ITS FUNCTIONS, ADMITTING AN ACCUMULATION OF FECULENT MATTER; OR THAT THE SECRETIONS FLOWING INTO IT ARE VITIATED OR DIMINISHED IN QUANTITY, WHICH WE DISCOVER BY THE PECULIARITY IN THE APPEARANCE, OR THE PUNGENT TASTE OF THE FLUIDS, WE MUST ENDEAVOUR, BYsteadily pursuing the purgative plan, to effect a change; for while this is produced in the appearance of the fluids, by the stimulating action of the medicines, a most important change is effected in the hepatic system, intestinal canal, and all the parts including every organ essential to life, which is by sympathetic connected with them. The purgative plan may be pursued without inducing dulness; on the contrary, with evident accretion of strength, so long as there is sufficiency of the bowels, either while the fluids are fetid and clay-coloured, or while they are dark and slimy. In the advanced stages, however, when the oily-looking, or glazed dark-green fluids, almost peculiar to this disease, are evacuated, we cannot hope to effect a cure by purgatives. BUT IN THE EARLIER PERIODS, SHOULDN'T LITTLE DIARRHOEA IN THE ALIMENTARY CANAL AND BILARY SECRECTIONS BE OBSERVED, IF THE STRENGTH OF THE PATIENT BE UMPIRED, AND HIS CONSTITUTION ORIGINALLY FOUND, THE EXHIBITION OF PURGATIVE MEDICINES, PERHAPS EVERY SECOND OR THIRD DAY, MAY BE ADVANTAGEOUS.

FOR THESE PURPOSES PREPARATIONS OF MERCURY, AND ESPECIALLY CALOMEL, APPEAR TO BE THE MOST SUITABLE, AS THE FIRST DOTES OF THEM SOMETIMES FAIL TO IMMEDIATE THE BOWELS. WHEN THIS DOES NOT OCCUR, AND THE PURGATIVE EFFECT IS NOT PRODUCED, SOME OTHER MEDICINE, AS JALAP, SLOES, SCAMMONY, MIGHT BE GIVEN IN ADDITION. DR. CHEYNE SAYS, "PURGES HAVE GENERALLY BEEN GIVEN IN THIS DISEASE; BUT, WHEN CALLED EARLY, WHAT I RECOMMEND IS, THE EXHIBITION OF THE LARGEST DOSE, WHICH CAN WITH SAFETY BE PRESCRIBED, OF SOME POWERFULLY CATHARTIC MEDICINE, TWO, THREE, OR FOUR TIMES A DAY, AND THIS CONTINUED FOR FEW DAYS, OR UNTIL NATURAL FLOWS ARE PRODUCED. THE ADVANTAGE OF KEEPING THE INTESTINAL CANAL UNDER THE CONTINUED INFLUENCE OF A STIMULUS, I HAVE, IN VARIOUS INANCES, FOUND TO BE SOMETHING GREAT, THAT I AM INDUCED TO REPEAT THE DECLARATION OF MY BELIEF, THAT THE HAPPIEST RESULT MAY BE EXPECTED FROM THIS MEASURE." P. 95.

IT MAY BE ADDED, THAT SHOULD THE SYMPTOMS INDICATIVE OF COMMENCING HYDROCEPHALUS, PROVE TO BE IN FACT THE SYMPTOMS OF REMITTIN FEVER, OR TO ARISE FROM WORMS IN THE INTESTINES, THIS PRACTICE FORTUNATELY PROVES THE MOST Efficacious MEANS OF REMOVING THESE DISEASES. ON THE WHOLE, THEREFORE, THE FREE ADMINISTRATION OF CATHARTICS MAY BE RECOMMENDED, UNDER ALL CIRCUMSTANCES, IN THE COMMENCEMENT OF THE DISEASE.

BLASTERS APPLIED OVER THE WHOLE SKIN, OR TO THE FOREHEAD, OCCIPUT, AND SIDES OF THE HEAD, IN SUCCESION, MAY BE CONSIDERED AS IMPORTANT PULSES IN RELIEVING THE INTERNAL INFLAMMATORY ACTION OF THE BRAIN; ESPECIALLY SOME EVACUATION OF BLOOD HAS BEEN PRODUCED. THEY OFTEN AFFORD OBVIOUS RELIEF TO THE PAIN, AND THEREFORE SHOULD NOT BE OMITTED AT ANY STAGE OF THE DISEASE. SEVERAL INANCES OF RECOVERY FROM HYDROCEPHALUS ARE ON RECORD, IN WHICH THE AGENCY OF BISTERS APPEARS TO HAVE CONSTITUTED A VERY IMPORTANT PART IN THE CURE. (SEE DR. QUIN, LOC. CIT.) THIS INTELLIGENT PHYSICIAN GENERALLY APPLIED A LARGE BISTERS OVER THE WHOLE HEAD, AND DRESSED IT WITH AN OINTMENT OF ANTIMONIUM: DR. CHEYNE USES THE STRONG MERCURIAL OINTMENT FOR THAT PURPOSE.

the absorbents, seem to render it a medicine of great promise in fulfilling the indication now under consideration, without endangering the life of a delicate child, in the same degree as blood-letting, it has been employed with apparent advantage. It is a medicine, however, of extreme uncertainty in its operation, and has not answered the expectations at first entertained of it in the cure of some other diseases: it can only be used, with any probability of success, when administered with activity, and it can only be given with safety in adequate doses, when its operation is carefully and unceasingly watched. Dr. Cheyne, who has well described the peculiarities of its operation, adds, "The method which I have for some time followed in using digitalis is the most obvious: it accords with the view which I have given of its powers, and does not appear ill adapted to the attainment of a safe and quick effect. I begin with a moderate dose, eight or ten drops of the saturated tincture, and to every succeeding dose, which is generally given at an interval of six hours, I add two or three drops; so that, in a day or two, generally some part of the system is affected. I proceed with great caution, ascertaining, while augmenting it, the effect of the medicine after each increased dose." P. 103.

In aid of the means of diminishing inflammatory action in the brain, already mentioned, the application of cold, or, more correctly speaking, the abstraction of heat from the head, particularly in the more acute forms of hydrocephalus, may be resorted to with advantage. Frequent washing of the face and neck with cold water, the application of linen cloths to the forehead wetted with cold vinegar or water, or with astringent (which produces cold by its rapid evaporation), contribute much to relieve the pain in the head. In a case mentioned by Dr. Rush, a solution of ice in vinegar appeared to afford the most obvious relief of this distressing symptom. Med. Inq. vol. ii. p. 227.

Of those individuals who have been known to recover from hydrocephalus, the greater number have taken mercury in one form or other; several of them to a very great extent, sometimes with the effect of inducing salivation, often without that result. Drs. Dobson and Percival first recommended and successfully employed that practice, (see Edinburgh Med. Comment. vol. vi. pp. 220 and 224,) and it has since been employed by other practitioners, with a happy effect, in a number of instances. (See many of the references to cases above given.) It has, indeed, frequently disappointed the hopes of the practitioner, even after salivation was induced; although, from the general difficulty of producing this discharge in patients labouring under hydrocephalus, it was at one time thought that the failure of mercury to accomplish a cure, arose from its failure to excite salivation. The superior success of the practice has been such, however, on the whole, that it will be admitted, with Dr. Cheyne, that "when the existence of the disease becomes probable, there ought to be no other delay than that occasioned by our endeavours to subdue the disorder in the bowels, in commencing a medicinal course, which, it must be allowed, has cured hydrocephalus, even when far advanced." That intelligent physician adds, that "it should give us more confidence in this remedy, that I have several times observed, when the mercurial stimulis was fully established, that the symptoms were interrupted, and the termination of the disease, although fatal, unlike what we find in cases where mercury has not been used. The convulsions were suspended; the frenzy, both external and internal, restored; the disease appeared to be checked; but the debility was such, that the vital functions languished; and the constitution had sustained to great a shock, that every effort to invigorate them was unavailing." Cheyne, loc. cit. p. 99.

The plan pursued by Dr. Percival, and subsequendy followed by others, consists in giving repeated doses of calomel internally, (such as the quantity of two grains at intervals of a few hours,) and at the same time using the strong mercurial ointment by friction upon the skin. It was suggested, that the salutary influence of the mercury was chiefly the operation of the calomel upon the alimentary canal and hepatic system; but Dr. Percival and other practitioners conceived that the effects of the remedy were decidedly more obvious and salutary, when it was thus administered in a twofold manner. We have been occasionally surprised, indeed, by the prodigious quantity of calomel which has been taken by children, in this disease, within a short space of time, without producing any obvious effect whatever, either on the bowels, the salivary glands, or the system at large. It is not easy to induce salivation in children under ordinary circumstances; but in this disease there is a peculiar degree of torpor in the advanced stages, which renders the constitution much less susceptible of the influence of medicine in the common doses.

Much has been written respecting the best method of restoring the strength of the patient after the decline of the disease. But in this, as in other instances of acute disease, when the great cause of irritation is removed, if there be any strength left, the system never fails to act with vigour, and requires little assistance from art. With the exception of a moderately nourishing diet, scarcely anything is required to further the progress of convalescence.

In regard to the prevention of hydrocephalus, perhaps the most important precept relates to a constant attention to the state of the bowels. "The mother must be taught," to adopt again the words of Dr. Cheyne, "to attend to and understand every irregularity in the state of her child's bowels. It is not merely colic and fever, which is to indicate the propriety of a purgative course; colic and fever is not to be neglected; but constitutional colic and fever is perhaps the sign of danger. Attention must be paid to every deviation (not absolutely temporary) from a natural appearance of the intestinal evacuation;" p. 108. (See Dejection.) The propriety of instituting a draught, by means of an issue or foment, in the neck, in the surviving children of families where the disease has already occurred, and in whom the marks of predispitation are visible, has been suggested and carried into execution, in some cases, with apparent success. In the family to which we formerly alluded, the half surviving child was supposéd to be preserved from the disease by the use of a foment in the neck; it may be remarked, however, that he has now, after attaining the adult age, become the subject of infirmity.

All the general means of supporting the general health in children predisposed by constitution to hydrocephalus, such as regular moderate exercise, the occasional use of the cold bath, regularity in diet, &c. must be combined with the attention to the state of the intestinal canal.

HYDROCERATOPHYLLON, in Bot. See CERATOPHYLLUM.

HYDROCHARIDES, a natural order of plants named from HYDROCHARIS, which is one of the genera; see the next article. This order is the 224 in Julliard's sytem, or the 4th of his 5th class, monocotyledon, flaminibus phyllis. The character he gives is, "Calyx of one leaf, superior, undivided, or divided, the segments disposed either in a simple or double row, the inner ones often petal-like. Stamine either definite or indefinite, situated upon the pith. German simples, inferior".

18
flora either simple, or definitely manifold, or none; Aigna simple or divided. Fruit inferior, of one or many cells. The plants are herbaceous aquatics.

As Jullien included the Cyamus, or Nelumbo, in this order, he was evidently in no position to make an exception, on account of its superior genus, but there having been scarcely any other reason for such an arrangement than its being a water plant, the cotyledons being one, and the other characters as different from the Hydrocharis as can well be, this difficulty is removed, and Cyamus goes to the Potamehoraceae, with Nymphæa, and Nuphar of Smith in Prod. Fl. Greece, Sibth. —The other genera in Jullien are Valvularia, Stratiotes, Hydrocharis, Trapa, Proserpinaca, and Pylita, the three last very dubious at best as to their claim to a place here.

Mr. R. Brown, in his Prodomus Nov. Holl. v. 1. 343, reckons Najas, Lomas, and Cherso, as akin to the natural order in question.

Gen. Ch. Male, Cal. Spathe three-flowered, of two leaves, obovate; perianth of three obovate-oblung, concave leaves, membraneous at the margin. Cor. Petals three, roundish, flat, large. Stam. Filaments five, awl-shaped, erect, arranged in three rows, of which the middle row puts forth an awl-shaped flim, from its inner base, like a style, which is placed in the centre; the other two rows are so connected at the base, that each inner filament coheres with the outer; authors simple. Pijl. none, except the above rudiment of a germen. Female. Cal. Spathe none; flowers solitary; perianth as in the male, superior. Cor. as in the male flowers. Pijl. Germen roundish, inferior; styles five, as long as the calyx, compressed, bifid, channelled; filaments white, pointed. Peric. Capsule leathery, roundish, five-celled. Seeds numerous, very small, roundish.

Obs. This genus is very nearly allied to Stratiotes.

1. H. Morfhus Ranz. Common Frog-bit. —Linn. Sp. Pl. 1466. Engl. Bot. t. 888. Curt. Lond. f. 3 t 64. (Morhus Ranz; Gen. Em. 818.) —Found on the surface of ditches and slow streams, plentifully in the neighborhood of London, flowering in July and Auguf. This perennial aquatic, every part of which is smooth, floats on the surface, throwing out from its joint clusters of leaves and flowers. Roots slender and simple, descending into the mud. Leaves on footstalks, kidney-shaped, entire, generally purplish beneath. The female stalks are quite simple, single-flowered, having a spathe at the base; males umbellate, three or four-flowered, with a pair of bractis at the base of the partial flower-stalks. Flowers white, elegant, and showy, with large, roundish, corrugated petals, yellow at the base. —Ray mentions a variety with fragrant double flowers, which Mr. Relham informs us is not now to be found in the place he indicates. Flowers with six petals now and then occur. Engl. Bot.

HYDROCHÆRIS, in A. Africarum, derived from Ægis, water, and Ænum, I pier. See Aquarius.

HYDROCORAX, in Ornithology. See Horn-bill.

Gen. Ch. Cal. Umbel generally simple; involucre most commonly of four leaves, small, perennial for any. Cor. Unifloral, uniform in figure, not in situatioll; all the flowers fertile; partial, of five ovate, acute, spreading, entire petals. Stam. Filaments five, awl-shaped, shorter than the corolla; anthers very minute. Pijl. Germen erect, compressed, circular, inferior, peltate; styles two, awl-shaped, very short; filaments simple. Peric. none; fruit orbicular, compressed, transversely divisible into two parts. Seeds two, semi-circular, compressed.

Linneus originally reckoned only five species of Hydrocotyle; professor Martyn enumerates fifteen, and Willdenow eighteen, from the Supplementum and other books. The author of English Botany observes that "the name of White-rot was given to H. vulgaris, from a supposition that this plant caused the disease in thyme called the rot; but it is doubtful if they will ever take it, and most people now attribute that disease to the animals inhabiting wet places, where indeed the Hydrocotyle grows, but which are in some other way noxious to their constitution."

The leaf of this plant is usually referred to as a perfect specimen of what Linneus intended for a peltate leaf. The common Nautrium of our gardens, Tropaeum majus, is however a more familiar and an equally correct name.

This species of Hydrocotyle is returned hither from Sibon solely on the authority of the Flora Britannica. This and the preceding are the only species indigenous to Great Britain.

Leaves peltate, umbels many-flowered. — Native of damp places in America, and particularly in Jamaica. — This species is very nearly allied to H. vulgaris, but differs in having the flower-alks twice as long as the leaves, and instead of five flowers, more than twenty crowded together so as to form a simple umbel.

4. H. bruniflora. Willd. n. 3. Lamarck Dict. v. 3, 153. — "Leaves somewhat peltate, kidney-shaped or roundish, crenate. Umbel compound; rays branched, flowering in the top and sides." — Found by Commerson on the sea-shore of Buenos Ayres near MonteVIDEO. — The whole plant is smooth. Branches trailing on the ground, a foot or more in length. Leaves on foot-alks, crenulatd, or obscurely lobed, having a sort of arch-work from the base to the centre. Foot-alks inferted close to the summit of this arch, so as to make the leaves umbilical or imperfectly peltate. Flowers yellowish.

5. H. americana. Linnae Sp. Pl. 338. Lecf. i. 281. — "Leaves kidney-shaped, somewhat lobed, crenate. Whorls four-flowered. — Native of both North and South America. — Similar in appearance and magnitude to H. vulgaris, but it differs in having its leaves separated half way down by a narrow sinus, their margin divided into nine oblong lobes, each of which is marked by three smaller crenulations. Umbel five-flowered. — A variety of this, much smaller in all its parts, appears in the Linnaian herbarium communicated by M. Cuffon.

7. H. nosophora. Willd. n. 6. Forth. Prod. n. 135. — Leaves kidney-shaped, seven-lobed, serrated, villose. Umbels many-flowered. — This is a native of New Zealand. We know nothing of it but from the authorities above quoted.

8. H. aficata. Linnae Sp. Pl. 338. (Rannunculo affinis; Pluk. Abyss. 314. t. 106. f. 5.) — "Leaves kidney-shaped, equally toothed or crenate." — Native of the East Indies and Cape of Good Hope, flowering in July. It was introduced into this country by Mr. F. Maifen in 1775. — This species is nearly allied to H. americana, but differs in having the dentations of its leaves equal or regular; the leaves are about three times as long, and almost hoary, with many foot-alks from the joints of the stem, whilit in H. americana the leaves are foliary.

10. H. crenata. Willd. n. 8. Linnae Suppl. 177. — "Leaves heart-shaped, crenate. Stalks with few flowers, the length of the leaf-alks. — Native of Jamaica. — Leaves obtuse, acutely dentated, an inch long; foot-alks radical, a span long, hairy at the top. Sepal radical, with a few flowers at their summit, erect, as is the whole plant, not creeping.

Leaves on foot-alks, undivided, resembling Viola sabulata. Flower-alks many, from the top of the stems, filiform, shorter than the leaves, single-flowered. Flowers small.

12. H. glabrata. Willd. Sp. Pl. n. 10. Linnae Suppl. 176. — Leaves oblong or lanceolate, acute, three- to five-lobed, smooth. — Found at the Cape of Good Hope. Whole plant extremely smooth. Stem angular, rigid, pubescent; leaves growing at the joints, and both leaves and flowers towards the summit of the stem.

13. H. Spananthe. Willd. Sp. Pl. n. 11. (Spananthe pauculata; Jacq. 1c. Rar. v. 2. t. 350.) — Stem erect. Leaves triangular, pointed, serrated, bearded at the base. — Native of South America. — Referred to this genus by Willdenow, of which we doubt the propriety. It has a tall branching stem, and prolific umbels.

15. H. paniculata. Willd. n. 13. Lamarck Dict. v. 3, 154. Illustr. t. 188. f. 1. — Leaves three or five-lobed, toothed. Umbel compound. — Gathered by Commerson at Buenos Ayres, and on his authority referred by Willdenow to this genus.

17. H. tridentata. Willd. n. 15. Linnae Suppl. 176. — Leaves linear-wedge-shaped, three-toothed at the top. — Found by Sparrmann at the Cape of Good Hope. — Very similar in habit to the preceding species, but differs in having the stem shorter, woolly, and not prostrate. Leaves with three equal teeth at their top. Flower-flalks much shorter than the leaf.

18. H. linifolia. Willd. n. 17. Linnae Suppl. 176. — Leaves linear-lanceolate, hirsute, entire. — A native also of the Cape of Good Hope, and very nearly akin to the following species.

HYDRODES Ferris, in Medicina, a fever in which the patient is, from the beginning, afflicted with very copious and weakening Sweats, and great weakness.

HYDRODYNAMICS, of which water, and $\delta_\text{m}^\text{v}$, force, is used for the science of the laws of the motions of fluids, and denotes much the same laws of the motions of fluids. See Fluid and Hydraulics.

HYDROENTEROCELE See HYDROENTEROCELE.

HYDROGEN, Hydrogenous Gas, or Inflammable Air, is an elatic fluid of extreme fubility and levity. It is ascertained to be nearly $\frac{1}{7}$th of the weight of an equal bulk of common air, or only $\frac{1}{1085}$th of the weight of an equal bulk of water, being by much the lightest ponderable substance with which we are acquainted. It is, on this account,
HYDROGEN.

that balloons are filled with it. The weight of a cubic foot of hydrogen gas, at the common temperature and pressure, is not more than \( \frac{21}{3} \) grains; whereas the volume of common air weighs \( \frac{31}{3} \) grains. It is not only in the chafic state that hydrogenous gas exhibits extreme leavity, but also the ultimate particle of it, according to the investigations of Mr. Dalton, is lighter than that of any other body, of which account he makes it the unit or standard of comparison in weight. See GAS.

Hydrogenous gas may be procured by various processes; the most simple and easy one is to take some turnings or filings of zinc or iron, and put them into a gas bottle, to which add their weight of water, and about \( \frac{2}{3} \)th of its volume of concentrated sulphuric acid. A violent effusion ensues, and the gas is generated in great abundance, and may be received over water in the usual way. The rationale of the process seems this; the metals have a strong affinity for oxygen, but not equally so for hydrogen; they are not of themselves sufficiently powerful to effect a union with the oxygen and a detachment of the hydrogen, but by the aid of the acid they can accomplish it, and the acid afterwards unites with the new compound or oxys, forming a salt, called a sulphate. Hence the hydrogen is derived from the water. Another method of obtaining hydrogen is to send flame over red-hot iron shavings in a gun-barrel; in this case, the iron unites with the oxygen, and the hydrogen is liberated in the gaseous form.

The properties of hydrogen gas are, 1st. It is the lightest of all gases, as has been observed, and may be proved, by actually weighing it in an air-bottle fitted up for such purposes, which has previously been exhausted and weighed. But there are several simple experiments by which it may be shown to be much lighter than common air; namely, if a jar be filled with hydrogen, and then uncovered for a moment, the hydrogen will escape, but not if the jar be placed with its mouth downwards, as will be proved by putting a lighted taper into the jar, which will not be affected in the former case, but extinguished with a slight explosion in the latter. If, instead of a jar, a tube of 12 inches long and \( \frac{1}{4} \) inch diameter be filled with hydrogen, it will be five minutes in losing one-half of its gas, and that the same whether held up or down. (See Nicholson’s Journal, vol. viii. p. 148.) This serves to shew that the effect of a difference in specific gravity is not perceived unless a sufficiently large volume or body of air can move together. If bubbles of soap and water be raised with hydrogen they ascend in the air like balloons. If a volume of hydrogen be gently placed over a volume of common air, they do not mix immediately, but in due time they are found mixed completely, whatever caution may be used to prevent agitation, and they remain mixed over afterwards. See Manchester Mem. vol. i. second Series, p. 261, and Memoriales d’Arcaud, tom. ii. p. 466. This curious fact, which is of a general nature, and by no means peculiar to hydrogen and common air, was first observed by Priestley, and is ascribed by Dalton to the mechanism of chafic fluids; but most others have thought it an effect of chemical affinity.

2d. Hydrogen gas is fatal to animals, as is proved by confining a mouse or other small animal in it for a few moments.

3d. It is inflammable. This quality is shewn by filling a taper to a phial of the gas with its mouth downwards; a slight explosion will be observed succeeded by a lambent flame. If a bladder be filled with the gas, and then the gas be gently driven out through a small tube, such as a tobacco-pipe, it will take fire with a candle and burn with a reddish flame. A mixture of one part hydrogen and two common air, or two hydrogen and one oxygen, in a small phial, exploses violently by being presented to a flame. The same effect may be produced by an electric spark in a glass vessel, called an inflammable air-pistol; or a strong brass tube, called Volta’s endimeter, may be partly filled with a mixture of hydrogen and oxygen, and the mixture expelled over water by electricity. In this way the quantity of hydrogen or oxygen in mixtures of gases may be ascertained. (See Eudiometry.) If a bladder, filled with hydrogen and common air, or oxygen, in the proportions above-mentioned, has its contents infused into bubbles of soap and water, they will explode with a loud report by a taper, and the bladder itself will burst with a tremendous report if the flame be applied to it or to the bubbles before they quit the pipe of the bladder.

4th. Hydrogen gas, though inflammable itself, yet extinguishes flame. If a jar of hydrogen be put over the flame of a candle, so as to surround it, the flame is instantly extinguished. 5th. A mixture of oxygen and hydrogen has been made to explode by mechanical contraction, by M. Biot. 6th. In the slow combustion of hydrogen, when the flame is confined in a long tube, under certain circumstances, a musical sound is produced. 7th. Hydrogen, when united to oxygen, produces water; when it is united to azote the product is ammonia; when united to carbon it forms carbonic gas, carbonated hydrogen, oil, &c. 8th. It contains half as many atoms in the same volume as oxygen gas.

HYDROGEN, Sulphuretted, in Chemistry, a compound of sulphur and hydrogen, which usually owes its origin to the decomposition of water in the processes by which it is formed, and is generated in various processes, in which its elements are preferred to each other in a nascent or condensed state. It was first procured from solutions in water of the compounds of sulphur with the fixed alkalies. When sulphur is combined with potash, soda, or lime, on dissolving the compound in water, a partial decomposition takes place; one part of the sulphur combines with part of the oxygen of the water, forming sulphuric acid, which unites with the potash; another part of the sulphur unites with the hydrogen of the water, forming sulphuretted hydrogen. This gas is produced likewise by expelling to a strong heat mixtures of sulphur with vegetable matter, as sugar, oil, or powdered charcoal; the hydrogen existing in vegetable substances combining with the sulphur; in these processes the gas is, very rarely, quite pure, or of an uniform composition. The specific gravity of sulphuretted hydrogen is to that of atmospheric air, as about 1.14 to 1.00, a hundred cubical inches weighing 33 grains. Its smell is extremely fetid; the effluvium diffused in putrefaction confiit chiefly of this gas. Its properties are, that it extinguishes combustion, and is wholly incapable of supporting animal life. It is asholed by water, the water taking up more than its volume, or 100 cubical inches of water will absorb 168 inches of this gas. It has a peculiar action on the metals, and tarnishes them very quickly, communicating shades of yellow, brown, or purple, with a diminution of metallic luster. This curious gas is polished the properties of an acid, enters into combination with the alkalies, and forms compounds, some of which are crystalizable. It is capable of changing vegetable colours to a red. It decomposes soap, combines with the metallic oxides, and precipitates sulphur from its combinations. The compounds of sulphuretted hydrogen with the fixed alkalies, are readily formed by passing a current of it in its chafic state through the alkaline solution. These compounds are called sulphuretters, which see. Sulphuretted hydrogen is capable of combining with an additional proportion of sulphur, and in this state the compound is denominated super-sulphuretted
retted Hydrogen. “The knowledge,” says Mr. Murray, in which we have acquired of sulphuretted hydrogen, and of its combinations, has thrown light on the composition of mineral sulphureous waters, and of the changes which they suffer. As sulphur is itself insoluble in water, and as frequently no traces of an alkali, by which it might be rendered soluble, could be discovered in these waters, chemists found it difficult to conjecture by what means its solubility was effected. The discovery of sulphuretted hydrogen, and of its solubility in water, solved this difficulty, and the mutual action exerted between it and oxygen, elucidates the changes these waters suffer from exposure to the air.” — Murray’s Chemistry, vol. 2. See MINERAL waters.

HYDROGEN, Super-sulphuretted. See HYDRO-SULPHURES.

HYDROGEN GAS, in Agriculture, the modern name of an effusive fluid, formerly denominated inflammable air. Its effects on vegetation have not yet been ascertained.

HYDROGETON, in Botany, from θείς, water, and γένεσις, a birth, from the circumstance of its being an aquatic plant. Such is the name given by Louririr, which is of a rather extensive application, but justifiable by the analogy of Potamogeton, which it evidently imitates. — Louririr. Cochin. v. 1. 244.—Chalp and order, Orthotricha Tetragynia. Nat. Ord. Insectes, Linn. Naturalis, Buff.

1. H. heterophyllum. Louririr, Cochin. v. 1. 244.—Native of native rivers and marshes in Cochinchina. Stem procumbent, long, branching, immersed in the water. Leaves entire, smooth. Flowers green, small, in oblong, arched, terminal, naked spikes.

Louririr observes that he separated the present genus from Potamogeton chiefly on account of the number of its filaments. Whether this distinction be sufficient to establish his genus, we greatly doubt, or rather, we think it quite inadequate. The Cochinchinese name of the plant is Ruong hai bi la.

HYDROGRAPHICAL Maps, more usually called sea charts, are projections of some part of the sea, in plano, for the use of navigation. In these are laid down all the rhumbs, or points, of the compass, the meridians, parallels, &c. with the coasts, capes, islands, rocks, shoals, shallows, &c. in their proper places, proportions, &c.

Christopher Columbus, the first great discoverer of America, was a man that earned his living by making and selling hydrographical maps. He happened to be a friend of the memoirs or journals of a noted pilot, one Alonso Sanchez de Huelva, captain of a ship, who, by chance, had been driven by a storm to the island of St. Domingo, and died at Columbus’s house soon after his return. This gave Columbus the first hint to attempt a discovery of the West Indies, in which he succeeded.

For the construction of the several kinds of hydrographical maps, see CHART.

For their uses, see SAILING.

HYDROGRAPHY, compounded of θέρα, aqua, water, and γραφή, to write, that part of geography which considers the sea; principally, as it is navigable.

Hydrography teaches how to describe and measure the sea; it gives an account of its tides, counter tides, currents, foundings, Kaia, gulfs, &c. as also of its rocks, shelves, sands, shallows, promontories, harbours, distances, &c. from port to port, with all that is remarkable, either out at sea, or on the coast.

Some of the best authors use the term in a more extensive sense; so as to denote the same with navigation.

In this sense hydrography includes the doctrine of sailing; the art of making sea charts, with the uses thereof; and every thing necessary to be known, in order to the safe and most expeditious performance of a voyage. See SAILING.

Hydrography is the most perfect of all the mathematical sciences; there being scarcely any thing wanting to its perfection, but the accurate discovery of the longitude.

The Jesuits Ricciolus, Fournier, and De Chales, have written on the subject of hydrography.

In France they have professors of hydrography established in all their sea-ports, who are to instruct the youth intended for the sea in all the parts of navigation, sailing, steering, &c. with the several branches of mathematics necessary thereto; as arithmetic, and the doctrine of the sphere, and trigonometry.

They are royal professors, and teach gratis; having faculties allowed them. They are also charged with the examination of pilots, &c.

Gen. Ch. Cal. Perianth of five, awl-shaped, erect, unequal, permanent leaves. Cor. of one petal, wheel-shaped or campanulate; tube shorter than the calyx; limb spreading, divided into five, ovate; incumbent, oblong segments. Stam. Filaments five, awl-shaped, incurved, heart-shaped at the base; anthers oblong, curved, incumbent. Pila. Germ superior, ovate; rays two or three, straight, six-sided, incurved and truncated. Peric. Capsules ovate, two-valved, two-celled, with a parallel partition. Seeds numerous, very small, imbricated; receptive ovate, large.

Obli. Aublet has remarked that in some flowers the calyx and corolla are fix-cleft, with fix filaments.

1. H. spinosa. Linn. Sp. Pl. 328. Aubl. Guian. 281. t. 110.—Leaves lanceolate, hairy. Flowers clustered, terminal. — Native of South America, particularly in most situations at Guiana and Cayenne, flowering at various times of the year. The whole plant is extremely bitter, having a fibrous root, from which arise one or more stems about three feet high, straitly, branched, woody, overgrown with a vicious downy. Leaves alternate, nearly sessile, lanceolate, entire, downy, clamy. Spines axillary, awl-shaped, straight, spreading. Flowers corymbose, of a blue colour, each one furnished with a foot of leafy calyx at the base.

3. H. trigyna. Willd. n. 2. Swartz. Ind. Occ. v. 1. 558.—Leaves
Leaves oblong, hairy. Flowers with three styles, axillary.

Found by Dr. Houton near Vera Cruz. Shrub armed with spines, hairy. Leaves alternate, sometimes approaching to nearly opposite, oblong, rather acute, entire. Spines foliary, half an inch long, spreading. Flowers blue, axillary, generally foliary, on stalks.

**HYDROLOGY**, compounded of ὑδρός, water, and ὑδροτελής, denotes that part of natural history which examines and explains the nature and properties of water in general. See Water.

**HYDROMANCY**, ὑδρομάντις, composed of ὕδρος, water, and μάντις, divination, the art, or art, of divining, or foretelling future events, by means of water.

Hydromancy is one of the four general kinds of divination (see Divination): the other three respecting the other elements, viz. fire, air, and earth, are denominated pyromancy, aeromancy, and geomancy.

Varro mentions the Persians as the first inventors of hydromancy, adding, that Numa Pompius, and Pythagoras, made use of it.

This species of divination was performed in various ways: sometimes they used invocations and magic ceremonies, in consequence of which they discovered the names of certain perfons, or events, which they wished to know upon the water: sometimes they suspended a ring by a thread over a vessel full of water, and shook the thread of the vessel with it a certain number of times; they also formed prefages by calling small flames into fill water, and observing the circles hereby formed on the surface of the water; by examining the various agitations of the waves of the sea; by observing the colour of the water, and the figures represented in it, &c. &c. See an account in Delrio Disquis. Magic. lib. iv. quæst. 6. féc. 3.

The writers in optics furnish us with divers hydrometric machines, vessels, &c.

To construct an hydrometric machine, by means whereof an image, or object, shall be removed out of the light of the reflecting object, and restored again, at pleasure, without altering the position, either of the one or the other. Provide two vessels, A B F, C G L K (Plate VIII. Hydrostatics, fig. 4.); the uppermost filled with water, and sustained by three little pillars, one whereof, B C, is hollow, and furnished with a cock B. Let the lower vessel C L be divided by a partition H I into two parts; the lower of which may be opened, or closed, by means of a cock at P.

Upon the partition place an image, which the reflector in O cannot see, by a direct ray G L.

If now the cock B be opened, the water descending into the cavity C I, the ray G L will be refracted from the perpendicular G R to O; so that the reflector will now see the object by the refracted ray O G. And again shutting the cock B, and opening the other P, the water will descend into the lower cavity H L; whence the refraction ceasing, no rays will now come from the object to the eye: but shutting the cock P again, and opening the other B, the water will fill the cavity again, and bring the object in light of O A r e f a l h.

To make an hydrometric vessel, which shall exhibit the images of external objects, as if swimming in water. Provided a cylindrical vessel A B C D (Plate VIII. Hydrostatics, fig. 5.) divided into two cavities by a glass E F, not perfectly polished: in G apply a lens convex on both sides; and in H incline a plain mirror, of an elliptic figure, under an angle of 45°; and let I H and H G be something less than the distance of the focus of the lens G: so that the place of the images of an object radiating through the same may fall within the cavity of the upper vessel: let the inner cavity be blackened, and the upper filled with clear water.

If, now, the vessel be diposed in a dark place, so that the lens be turned towards an object illuminated by the sun, its image will be seen as swimming in the water.

**HYDROMEL, ὑδρομέλλις**, composed of ὕδρος, water, and μέλις, honey, a drink made of water and honey, nearly in equal quantities; called also by the Greeks, μελαιομέλλις.

When this liquor has not fermented, it is called simple hydromel, and compound when other ingredients are added to the water and honey, in order to improve and exalt the flavour and virtues.

When it has undergone the spiritual fermentation, it is called the σάμινα hydromel, or mead and meatholin. To induce this fermentation, nothing is necessary but to dilute the honey sufficiently in water, and to expel the liquor to a convenient degree of heat.

Hydromel is the common drink of the Poles and Ruffians. Diiodorus Siculus, lib. v. and Aristolot, relate, that the Celts, and Taulantii, ancient people of Illyria, drank hydromel instead of wine.

**HYDROMELON, a name given by the ancients to a liquor prepared with one part of honey, impregnated with the juice of quinces, and two parts of boiled water, let in the sun during the dog-days.**

**HYDROMETER, compound of ὑδρός, water, and μέτρον, measure, an instrument wherewith to measure the gravity, density, velocity, force, or other properties of water.**

The extensive use of the knowledge of the specific gravities of bodies has produced a variety of contrivances, under the name of Effay Instrument, Hydrometer, Aemometer, Gravimeter, Pefi-liqueur or Water-poise, for the purpose of ascertaining the specific gravities of different bodies, both solid and fluid, in an expeditious manner.

From Lowthorp's abridgment of the Philosophical Transactions, vol. i. p. 516, &c. or Boyle's Works, 40. London ed. 1772. vol. i. p. 204, &c. it appears, that the hydrometer was first invented by Boyle, and described under the name of a New Effay Instrument. It consisted of a ball, somewhat less than an hen's egg, with a graduated item, four or five inches in length, folded to the upper part, and by means of a silk or silk piece of brass underneath, it was applied, as perfectly as a graduated instrument could be, to ascertain the specific gravities of solids as well as fluids.

To extend the use of the instrument, Boyle proposes that the ball should be made large, and provided with an appendage for occasionally changing the quantity of ballast applied beneath the ball. (See Aemometer) Boyle's instrument was intended to be used in water, and, consequently, the graduations of its item denoted certain invariable weights. But when the hydrometer is to be used in various fluids, it diminishes the accuracy of the results, if those spaces be taken for absolute weights; or, at all events, it brings forward a rather intricate consideration of the relation which the anches of the spaces, or parts of the item, have to the whole immersed part. Hence Fahrenheit first applied a dial, or scale, for weights at the top, in order to ascertain the specific gravities of fluids truly, and his instrument had only a single mark, that, in all cases, was to be brought to the surface of the fluid, by means of weights added in the above-mentioned scale;
HYDROMETER.

scale; as may be seen in Reid and Grey's abridgment of the Phil. Trans. vol. vi. pt. 1. p. 294.

The general principle on which the construction and use of the hydrometer depends, has been illustrated under the article specific Gravity: for it has there been shown, that a body specifically lighter than several fluids will serve to find out their specific gravities; because it will sink deepest in the fluid whose specific gravity is the heaviest, or, that a greater addition of weight is required to keep the same part of the floating body below the surface of a heavier than of a lighter fluid.

Thus, let A B, (Plate IX. Hydrometer, fig. 1.) be a small glass tube, hermetically sealed, having a scale of equal divisions marked upon it, with a hollow ball of about an inch in diameter at bottom, and a smaller ball C under it, communicating with the float. Into the little ball put mercury or small shot, before the tube be sealed, so that it may sink in water below the ball, and stand upright, the divisions on the float showing how far it sinks. If this instrument be dipped in common water and sink to D, it will sink only to E in salt water; but in port wine it will sink to F, and in brandy under proof, it will perhaps sink to B. It is evident that an hydrometer of this kind will only shew that one liquid is specifically heavier than another; but the true specific weight of any liquid cannot be determined without a calculation for this particular instrument for the tube of which should be truly cylindric, and not tapering as they commonly are. Besides, these instruments will not serve for fluids, whose densities are considerably different. With a view of remedying these and some other inconveniences, Mr. Clark, in the year 1739, seemingly unapprized of what had been done before by Boyle and Fahrenheit, constructed a new hydrometer, for the use of dealers in brandy and spirits, that they might be able to determine, by inspection, whether any spirituous liquor be proof, above proof, or under proof, and exactly in what degree. This instrument is made of copper, because ivory imbibes spirituous liquids, and glass is apt to break. It consists of a brass wire about one-fourth of an inch thick, passing through and soldered into the copper ball B, (see fig. 2.) The upper part of the wire is fixed flat on one side of the stem of the hydrometer, and marked at m, to which division it exactly links in proof-spirits. There are two other marks A and B; the one showing that the liquor is one-tenth above proof, when this division links to A, and the other indicating one-tenth under proof when it emerges to B; a brass wire, as C, having been previously screwed on to the bottom at c. There is a great variety of weights of different sizes, as K, &c. adapted to liquors that differ more than one-tenth from proof, and for determining the specific gravities of all such liquors as occur in trade, as well as for shewing the specific gravities of all fluids quite to common water. The round part of the wire above the ball may be marked across, as in fig. 3, so that with the weight as C, which fits the instrument for the trial of river water, in which it sinks to R W, it may serve for wines or other waters: thus in spring water it will sink to S P; in mineral water to M 1; in sea-water to E; and in the water of salt springs to S A; and the marks br, ra, po, m, denote the divisions to which the instrument descends in Brindled water, rain water, Port wine, and Mountain wine, respectively. Phil. Trans. Abr. vol. vi. p. 326, &c.

This hydrometer, says Mr. W. Nichollon, (ubi infra), is inferior to Fahrenheit's in two respects. In the first place, either a bubble of air, or a portion of the fluid, will be hid in that part of the cavity of the ball which, as it is not filled by the screw; and it is of very different

Vol. XVIII.
different specific gravities of spirits by experiments made at numerous varieties of strength and temperature.

Mr. Quin's hydrometer has been recommended by many distillers, &c. on account of its accuracy, which requires only eighteen weights used on the top of the instrument, to shew all the under and over proofs to the certainty of one pint in a hundred gallons, from proof to seventy gallons to one hundred over proof, and to fifty gallons in a hundred under proof, which would require nine hundred and sixty-eight weights, besides forty-five air weights, according to the old construction of Clark's hydrometers. The weights are numbered 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25, 30, 35, 40, 45, 50, 60, 70, 80, 90, 100, 150, 200, 250, 300, 600, grains. He has also formed a table shewing the degrees of the thermometer, and the number of grains corresponding with each degree; the number of grains required for each strength; the over proofs, or the quantity of water necessary to reduce one hundred gallons of spirit to proof, with the former manner of expressing the several preparations, as one to two, one to three, &c. and likewise the under proofs.

There is one circumstance, which deserves particular attention in the construction and graduation of hydrometers for determining the precise strength of different brands, and other spirituous liquors. M. Réaumur, in making his spirit thermometers, discovered, that when rectified spirit and water, or phlegm, the other constituent part of brandy, are mixed together, there appears to be a mutual penetration of the two liquors, and not merely juxtaposition of parts; so that a part of the one fluid seems to be received into the pores of the other; thus, e.g. if a pint of rectified spirit be added to a pint of water, the mixture will be sensibly less than a quart. The variations hereby produced in the bulk of the mixed fluid render the hydrometer, when graduated in the usual way, by equal divisions, an erroneous measure of its strength; because the specific gravity of the compound is found not to correspond to the mean gravity of the two ingredients. M. Montigny constructed a scale for this instrument in the manner before suggested by Dr. Lewis, on actual observation of the sinking or rising of the hydrometer in various mixtures of alcohol and water, made in certain known proportions. Hift. de l'Acad. Roy. Sciences, &c. Paris, for 1768. Memoire sur la Thermomètre. M. de Luc has published a scheme of the construction of a comparable hydrometer, so that a workman, after having constructed one after his principles, may make all others similar to each other, and capable of indicating the same degree on the scale, when immersed in the same liquor of the same temperature.

For this purpose he proposes to use a hydrometer of the common construction, such as is represented in fig. 5, made of Flint glass, because glass is a substance which undergoes the least change of bulk by heat, and its changes are the most regular. The ball a should be one and a half inch in diameter, with which should communicate a small hollow cylinder b, containing such a quantity of quicksilver for a ballast, that the instrument may sink nearly to the top in the most spirituous liquor, made as hot as possible. To the ball a is cemented a thin brass tube filtered over, or a silver tube c, made perfectly cylindrical, by drawing it through a hole. This tube, or brassly, as he calls it, should be long enough to admit the immersion of a small part of it in the lea spirituous liquor, e.g. wine reduced to congelation. In order to determine a standard for the construction of the scale of this instrument, he forms a weak spirit of wine, by mixing one part of water with five parts of such spirits of wine as fire gun-powder, or Lique refined in them. He also finds the specific gravity of the mixture, at the temperature of fifty-four and a half of Fahrenheit's thermometer, by a nice hydrostatical balance. Having dipped the hydrometer into this spirit of wine, at the fixed temperature, he marks upon its branch or stem with a thread, the point to which it sinks; then preparing a port of brandy stronger than the common, by mixing three parts of water with seven parts of this same spirit of wine, he determines the point on the stem to which the instrument would sink in at the same temperature, and marks it with a thread. These points, viz. 45 and 15 in the figure, are the fixed points of the hydrometer. The interval between them may be divided into thirty equal parts, each of which will represent one-thirtieth of the total effect of the superadded water, on the specific gravity of the liquor. This fundamental interval in instruments for common use may be divided into fifteen parts, which will then be double-degrees. In order to find a convenient place for the 0 of this scale, M. De Luc proposes to reduce one of the wines of which brandy is commonly made, to the temperature of water in ice, and dipping the hydrometer in it, to observe how much higher it will stand than the inferior fixed point. This excess of emERSION, compared with the fundamental scale, and reduced to the nearest number of degrees, which will be an aliquot part of it, will be a proportional quantity invariably fixed, to be added to the scale below the inferior fixed point, for determining the place of e, &c. let this excess of emERSION be about 15, or half the fundamental scale; then one should constantly add half the fundamental distance below the inferior fixed point, and thence begin to count the degrees: so that 0 would be at the bottom of the whole scale, the inferior fixed point would be at 15, the superior at 45, and the scale could be prolonged at the top as much as may be necessary for the essays of the most spirituous liquors. Another scale may be applied on the opposite side of the stem, for trying merely the specific gravity of the liquids in which the hydrometer may be dipped. The particular fixed points of this scale, e.g. d, may be taken in any two liquids, whose specific gravities, tried by the hydrometrical balance, shall have a convenient relation, and the space between those two points will be divided into a convenient number of equal parts. For the correction on account of the differences of heat, M. De Luc would take a liquor of mean spirituality, e.g. a mixture of one part of water, and seven parts of the spirits of wine, determined by the hydrometrical balance; reduce this liquor to the temperature of 45 of Fahrenheit; plunge into it the hydrometer already graduated, and observe the point to which it sinks; he proposes afterwards to heat the liquor to 65, and then to observe the sinking of the instrument. From this observation a table might easily be formed, in which we might express in degrees of the hydrometer, the effects of the differences of heat corresponding to each degree of the thermometer, beginning from a fixed point; or, a particular scale might be prepared for experiments of this nature, by changing the number of degrees contained between the fixed points, in order to establish an easy proportion between them and the degrees of the aerometer; and thus the correction might be made without tables. If an hydrometer of this kind were brought into general ufe, the police of the places in which the trade of spirituous liquors is carried on might take cognizance of it; and keep the public standard of the hydrometer of aerometer, as they keep the standard of weights and measures. Phil. Trans. vol. lxviii. part 1, art. 20. p. 500, &c. M. Le Roi has also published a proposal for constructing comparable hydrometers. Hift. de l'Acad. des Scien. Paris, for 1770. Mem. 7.

Mr. William Nichollson some years ago made an attempt
to combine Boyle's and Fahrenheit's instruments, and thus to adapt the hydrometer to the general purpose of finding the specific gravity of both solids and fluids. A (fig. 6) is a hollow ball of copper; B is a dish affixed to the ball by a short slender rod C; C is another dish affixed to the opposite side of the ball by a kind of bifurcated pin. In the instrument actually made by the inventor, the item D is of hardened steel, 3/4 of an inch in diameter, and the dish C is so heavy as to cause the item vertical, when the instrument is made to float in any liquid. The parts are so adjusted, that the addition of 1000 grains in the upper dish B, will just sink it in distilled water, at the temperature of 60° of Fahrenheit's thermometer, so that the surface shall intersect the middle of the item D. Let it be required to find the specific gravity of any fluid. Immerse the instrument in it, and by placing weights in the dish B cause it to float, so that the middle of the item D shall be cut by the surface of the fluid. Then, as the known weight of the instrument, added to 1000 grains, is to the fame known weight added to the weights used in producing the fall of equilibrium, so is the weight of a quantity of distilled water replaced by the floating instrument, to the weight of an equal bulk of the fluid under consideration. And these weights give the ratio of the specific gravities. (See Specific Gravity.) Again, let it be required to find the specific gravity of a solid body less than 1000 grains. Place the instrument in distilled water, and put the body in the dish B. Make the adjustment of sinking the instrument to the middle of the item, by adding weights in the same dish. Take these weights from 1000 grains, and the remainder will be the weight of the body. Place now the body in the lower dish C, and add more weight in the upper dish B, till the adjustment is again obtained. The weight last added will be the loss of the fluid, and the weight is that of the weight of an equal bulk of water. Consequently the specific gravity of the fluid compared with water is as its weight to the loss it sustains by immersion. (See Specific Gravity.) When the instrument has been once adjusted in distilled water, common water may be afterwards used. Now the ratio of the specific gravity of the water made use of to that of distilled water being known \( = \frac{a}{b} \), and the ratio of the specific gravity of the solid to the water made use of being also known \( = \frac{c}{b} \), the ratio of the specific gravity of the solid to that of distilled water will be compounded of both, (that is, \( \frac{ab}{c} \)). This instrument has been found to be sufficiently accurate to give weights true to less than one-twentieth of a grain. Manch'ester Memoirs, vol. ii. p. 386; &c. Nicholson's Introd. to Nat. Phil. vol. ii.

The hydrometer of Mr. Nicholsson is highly commended by citizen Guyton in the description which he has given of a gravimeter, or instrument for measuring the specific gravity of solids and fluids, read to the National Institute at Paris, and inserted in the 21st volume of the Annales de Chemie. At present, he says, it is very much used; and gives, with considerable accuracy, the ratio of the specific gravity to the fifth decimal, water being taken as unity. It is susceptible of correction for the variations of temperature, and the impurity of the water which it is sometimes more convenient to use. It does not appear that any better instrument is wished for in this respect. But this instrument, having hitherto been constructed in metal only, could not be applied either to fluids or acids. M. Guyton, in order to remedy this and some other inconveniences to which hydrometers are subject, has proposed, by following the principles of Fahrenheit, and executing the instrument of Nicholsson in glass, with a slight addition, to render it more generally useful and commodious, without diminishing its accuracy in any respect. To his instrument he has applied the name of gravimeter. It is made of glass, of a cylindrical form, and being that which requires the smallest quantity of the fluid. Like the instrument of Nicholsson it carries two bafons; the one superior, at the extremity of a thin item, towards the middle of which the fixed point of immersion is marked. The other lower bason terminates in a point; it contains the ballast, and is attached to the cylinder by two branches. The moveable suspension, by means of a hook, has the inconvenience of shortening the lever which is to secure the vertical position. The cylinder is 22 millimeters (.871 inches) in diameter, and 21 centimeters (.857 inches) in height. It carries in the upper bason an additional constant weight of five grammes. Guyton has added a piece which he calls the diver (plongeur), because it is in fact placed in the lower bason when used, and consequently is entirely immersed in the fluid. This is a bulb of glass, loaded with a sufficient quantity of mercury, in order that its total weight may be equal to the constant additional weight, added to the weight of the volume of water displaced by this piece. The weight, being determined at the same temperature at which the instrument was originally adjusted, will sink to the same mark on the item, whether it be loaded with a constant additional weight in the upper bason, or whether the effect of this weight is produced by the additional piece (plongeur) in the lower dish. In using this instrument for solids, it differs in no respect from the hydrometer of Nicholsson. The only conditions being, like that in his, that the absolute weight of the body to be examined should be rather less than the constant additional weight, which in this instrument is five grammes (115 grains). The instrument, without the above additional weight, weighs about two decagrammes (459 grains) in the dimensions before laid down. We have therefore the range of one-fifth of bionyane, and consequently the means of ascertaining all the intermediate densities from water to the most highly rectified spirit of wine, which is known to bear in this respect the ratio of eight to ten with regard to water. When liquids of greater specific gravity than water are to be tried, the constant weight being applied below, by means of the additional piece (plongeur), which weighs about six grammes (138 grains), the instrument can receive in the upper bason more than four times the usual additional weight, without losing the equilibrium of its vertical position. In this state it is capable of shewing the specific gravity of the most concentrated acids. It poises another property in common with the instrument of Nicholsson, viz. that it may be used as a balance to determine the absolute weight of such bodies as do not exceed its additional load. And, lastly, the purity of the water being true, it will indicate the degrees of rarefaction and condensation in proportion to its own bulk. This instrument is rendered portable by means of a case, in which all the delicate parts are secured from pressure, and the heavier parts supported as to refill the excess of motion which they are capable of acquiring in consequence of their mass. For a further account of this instrument, illustrated by figures, the manner of using it, and its application to the results of tables of specific gravity, we refer to Nicholsson's Journal, vol. i.
of water in its cavity, independent of pregnancy, ever occurs, it is at least a very rare disease, and its symptoms are not easily detected. Dr. Cullen, however, has given such a disease a place in his system of pathology, although he has made no mention of it in his Treatises. (Nofof. Method. Gen. lxxx.) Boerhaave mentions it in his 124th aphorism; but the commentary of Van Swieten seems to relate principally to larger collections than usual of the fluids in the gravid uterus. Sauvages speaks of a simple droopy of the cavity of the uterus on the authority of Altrane (Hydrometra aficiens, &c.), and includes the ovarian droopy under the same genus, as well as the formation of hydatids in the uterus (H. hydrametra), which, however, is altogether distinct from the true droopy. (Nofof. Method. Clas. x. Gen. 15.) See Dropsy.

HYDROMETRIA, HYDROMETRY, the mensuration of water, and other fluid bodies, their gravity, force, velocity, quantity, &c.

Hydrometry includes both hydrometries and hydraulics.

The term is modern, but very little in use. The first instance where we meet with it, is in the year 1694, when a new chair, or professorship of hydrometry was founded in the university of Bologna, in favour of S. Guglielmimi, who had carried the doctrine of running waters, with respect to rivers, canals, dykes, bridges, &c., to an unusual length. HYDROMETRIA, in Botany, a droopy of swelling of the navel. The word is compounded of *edema*, water, and *caput*, the navel. See Dropsy.

HYDROMYSTES, or HYDROMISTA, compounded of *edema*, water, and *forma*, a person set apart for the office of religion, a name anciently given to certain officers in the Greek church, whose business was to make the holy water, and sprinkle it on the people.

HYDROPARASMATAE, or HYDROPARASTAE, formed of *edema*, water, and *parasites*, I presume, in Ecclesiastical History, a sect of heretics, the followers of Tatian; called also Encratites, Apotaetites, Saccophori, Sewarders, and Aquarians.

The hydroparastae were a branch of Manichees, whose doting guimets was, that water should be used in the eucharist instead of wine.

Gen. Ch. Cal. none. Cor. Petals fix, oblong, permanent, somewhat spreading; the three outermost short, and externally resembling a calyx. Stam. Filaments numerous, about 36, inserted into the receptacle, thread-shaped, much shorter than the corolla; anthers vertical, erect, oblong, obtuse. Pfl. Gernem ferval, about 12 or 16, superior, erect, oblong, acute, each fertile on a mammillar point of the receptacle; styles short, thread-shaped, incurved; stigma obtuse. Ber. Capsules several, included in the permanent corolla which exceeds them in length, erect, oblong-ovate, pointed, somewhat fleshy, of one cell, not birnelling. Seeds one or two, somewhat globous, infected at the future on the inner edge of the capsule. Sefl. Ch. Calyx none. Petals fix, permanent; three of them external and shortet. Neclaries none. Capsules several, superior, with one cell and two seeds.

Obf. The feed is described by Mr. Konig as monoco
tyledonous, if so it cannot belong to the Ranunculaceae. Aquatic plants in general require reconsideration in this respect, some of them, as we have observed, having been judged monocotyledonous by analogy only, and few properly investigated. The late Dr. Solander had made a genus of this plant which he referred to the Linnaean natural order of Multifilae, and called Isodius, from *isodius*, *wijfis*, very aptly alluding to the extremely vivid coating of the young shoots and buds, which is inoffolable in water; but the name given by Michaux being printed, and liable to no exception, is properly retained by Dr. Sims.

The only known species is

1. H. purpurea. Michaux. Boreal.-Amer. v. 1. 324. t. 29. Curt. Mag. 1. 147.—Native of lakes and still pools in North America, from Upper Canada to South Carolina. It was communicated to Dr. Sims from the late collection of E. J. Woodford, esq. at Springwell, Herts. The stems are long, floating, round, and leafy. Leaves alternate, stalked, floating, orbicular, entire, peltate, with many veins radiating from their centre, and branching towards the margin. Flower-flats from the side of the leaf-flats, simple, single-flowered. Flowers dull purple, closing and lying down on the surface of the water at night, and expanding again in the morning, like those of Nymphaea alba, as observed by Mr. S. Edwards while making his drawing for the Botanical Magazine.

HYDROPHACE. See Lemna.

HYDROPHANES, in Botanyology, some varieties of opal which appear to have lost the water which they naturally contain, from exposure to the air, and in consequence of this have become opaque, recover their transparency when imdered in water; these have been named hydrophanes. See Opal.

HYDROPHILUS, in Entomology, a genus of the aquatic kind of coleoptera, nearly allied in appearance and manners of life to the dytiscus; its generic distinction consists in having the antennae elevated, and the club perforated; the feelers four and filiform; and the posterior legs formed for swimming, with the inner edge in general ciliated and armed with small claws.

Linnaeus has not very accurately discriminated the difference between the dytiscus and the hydrophilus, both which he confounds under the comprehensive term dytiscus, excepting only that he divides this genus into two sections, one having elevated and perforated antennae (as in hydrophilus) and the other antennae of a facetous structure. His generic character is consequently adapted to include both those sections, and is for this reason rather curiously, and somewhat too loosely defined; the antennae of the dytiscus, says Linnaeus, are either facetous, or increase in size towards the end, and have a perforated capitulum or head; the hind feet hairy, formed for swimming, and armed with small claws. (Ord. et Gen.) And again in Syll. Nat. "Antenna facetaus aut clavato-perforata; pedes politi villosi, nataorti submotici." In the tenth edition of Syll. Nat. Linnaeus however divides the dytiscus into three sections instead of two, as *Antenna perfoliata*, *Antenna facetata*, and **Antenna elevatae*. Ray had long before his time called this tribe of water beetles by the significant term of hydrocanthares.

The dytiscus genus, as established by Linnaeus, is separated by Geoffroy into two genera, dytiscus and hydrophilus, the latter of which, according to this author, contains those with perforated antennae (which he observes are shorter than the feelers); the rest, having the antennae filiform, (and longer than the head,) he retains under the name assigned to them by Linnaeus. Scheffer admits the two last-mentioned genera with some amendment; the tarsi of the dytiscus, he remarks, have five joints, the body oblong, and the head obtuse. The mouth of the hydrophilus, according to this author, is armed with jaws, and has four palpi or feelers, two of which are longer and two shorter than the antennae.
In the Gmelinian edition of "Sytema Naturae," the two genera hydrophilus and dyticus are adopted nearly in the manner of the writers last-mentioned, except that, according to Fabricius, he adds that the hydrophilus have only four feelers, the dytici fix. Lamark again observes of the "hydrophilus" (hydrophilus), that the antennae are short, with a perforated club; feelers four and unequal, the anterior ones longer than the antennae. The "dytici" (dyticus,) he adds, has filiform-facetous antennae of the same length as the corful (thorax); six unequal feelers; and simple jaws ciliated within. The body in both, he says, is elliptic; in hydrophilus the sternum is spinous; and the four posterior legs formed for swimming, in dyticus only the two behind. Mr. Marsham notices the trifid structure of the antennae in the hydrophilus, the perforated position of the head, the oval convex form of the body, and the ciliated observable on the posterior legs in most species, "Antennae clava perforata, trifida, palpis brevis; caput informent; thorax transversus; corpus oval, convexum; pedes pollici in perifilium ciliat." Ent. Brit. And these he divides into two families, the one having the thorax smooth, the other longitudinally rugose.

The hydrophilus either as a genus (hydrophilus), or a family (hydrophilini), containing several distinct genera, appear to have been long since admitted among the French writers. Walecker, in his "Faune Parlementaire," has the genera sphericus (from Fabricius) and alio hydrochius, in addition to hydrophilus and dyticus, all which belong, according to most other writers, to one of the two genera last-mentioned. In describing the hydrophilus, he notices the cleft on the jaw, and the texture as well as form of the lip, in addition to the characters alligned to it by others. "Palpes, quatro aliofiliformes. Machiore bifide. Lèvre cornée, légèrement écaillure. Languette légèrement échancrée. Antenna en mafie poiffurée." The family hydrophilini, as a sub-division of the "Sphéridiotes," is described at some length by Olivier; from which they have been lately removed by Latreille, and now constitute the fourteenth family of the "Pentameures."

Latreille divides the hydrophilini into two sections, one of which has the jaws entire at their extremity, the maxillary feelers rather shorter than the antennae, the body oblong and nearly plain above, and the breadth of the thorax never much exceeding its length. This section contains the two genera elaphorus and hydrochina (the hydrochina of Illiger.) The insects of the second section are known by having the jaws bifidated at their extremity; the maxillary feelers also as long, or longer than the antennae; the body hemispherical, or ovoid and convex; and the thorax transverse. This last contains likewise two genera, as sphericus and hydrophilus. The genus elaphorus is distinguished by elevated antennae, the club of which commences at the sixth joint; and the feelers terminate in a large ova joint. The club of the antennae in hydrochina begins at the third articulation; and the feelers end in a joint much smaller or thinner than that of the preceding. In sphericus the antennae consist of six joints, and the limbs are defelute of conspicuous spines, or spurs. And lastly, that genus, to which the name of hydrophilus is retained, includes those only which have nine joints in the antennae, and the limbs terminated in a kind of spurs or spines. The greater number, if not the whole, of those, appear to be hydrophilus of continental writers in other parts of Europe.

Like the dytici the hydrophilus inhabit ponds of stagnant waters, residing in the aquatic element during the day-time, and venturing abroad on the wing in the night feasi, at which period they become the prey of the owl, the great-fuck, and other nocturnal birds. The males are distinguished from the females by having a horny flap or shield of a concave form on the anterior legs. The posterior legs are adapted in an admirable and peculiar manner to its mode of life, being long, curved, and flattish, and furnished on the inner side with a series of close-fet filaments, resembling a fin, by means of which it is enabled to swim, and perform its various evolutions in the water with the utmost ease and velocity. The larvae, as in the dytici, are hexapodal creatures which live in the waters and prey upon insects, the fry of fishes, and other inhabitants of its aquatic regions. It is supposed to live between two and three years in the state of larva before it assumes the pupa form, previous to which latter change it buries itself in some bank of earth or sand contiguous to the boundaries of its usual haunts, and remains, while in the state of pupa, inclosed within a covering of its own formation, the shape of which is usually oval or spherical. The opinion of Degeer that the hydrophilus, in the larva or winged state, are carnivorous, seems to be in some degree refuted by the more recent observations of naturalists, the refutations which appears to be that they subsist chiefly, if not entirely, on vegetable food; and we may further add that their internal conformation pretty clearly proves the truth of this interesting discovery.

Species.

Native of Europe.

Olivacea. Olive, sternum grooved with a long recurved spine; wing-cafes emarginate. Fabr.

Inhabits Coromandel, and fels than the former.

An European species.

Lateralis. Black and glossy; margin of the thorax and wing-cafes yellow. Fabr.

Half the size of the former, the sternum projecting backwards into a sharp point, with a yellow dot in the middle, and the legs ferrugineous. Inhabits South America.

Rufipes. Shifting black; legs rufous; sternum with a recurved spine. Fabr.

Size of the last, and inhabits China. The antennae are ferrugineous, with the club brown; the body glabrous, and without spots.

Emarginatus. Dukiy-brown; shield emarginate. Fabr. &c.

Found on aquatic plants in Europe. Body gibbous and opaque.

An European species.

Native of waters in Europe.

Piceus. Black; legs pitchy; wing-cafes smooth. Fabr.

Inhabits Germany.

Oreiculatis. Subround; body glabrous and black; Fabr. L'Hydrophilus à points, Geoff.

Sams
HYDROPHILUS.

Same country as the preceding; and is likewise found in France and other parts of Europe.

Subrotundus. Roundish, glabrous and black; wing-cafes frirated. Fabr. Smaller than the last, and inhabits America.

Bicolor. Ovate; above yellowish, beneath black. Fabr. 

Native of Denmark.

Collaris. Black; mouth, thorax at the sides, and a few abbreviated lines on the wing-cafes rufous. Fabr. Inhabits South America.

Umbatus. Ovate, black; thorax pale; wing-cafes frirated grey. Fabr. The head of this species is glossy black; antennæ and feelers yellow; thorax with a double black dorsal line; wing-cafes obscurely undulated with black; body black, and legs yellow. This insect inhabits South America.

Oscillus. Glossy black; wing-cafes frirated and ferruginous at the base and tip. Fabr. Inhabits Germany.

Native of Germany; the head and thorax smooth and without spots; legs somewhat ferruginous. Obs. This must not be confounded with hydrophilus obscurus of Müller (Zool. Dan.), which is described of a livid colour, with the abdomen black, and the wing-cafes glossy with crowded spots. This last mentioned insect is perhaps a variety of the following species.

Inhabits Europe.

Hemorrhoidalis. Black; wing-cafes frirated, the tip with the flanks ferruginous. Fabr. &c. 

Inhabits Germany.

Marginalis. Glossy black; thorax and wing-cafes edged with rufous. Fabr. 

Size of the last, and inhabits the same country; the wing-cafes smooth; legs black; thorax ferruginous.

Sordidus. Black, and somewhat glossy; margin of the thorax livid; wing-cafes livid, with black spots. Marsh. Inhabits Britain in flagrant waters.

Vulgaris. Dull black, ferruginous; abdomen beneath vcracoce. Marsh. 

Legs and abdomen black; tubeceles beneath resembling those on some species of the Lichen genus. Native of Britain.

Antennæ flagrant at the base; legs black, the flanks and thorax ferruginous. Found in maritime marshes in Europe.

Dermestoides. Hemispherical-ovate, and lurid; head black; thorax at the sides dull ferruginous. Marsh. Diffusus dermestoides, Forl. 

Inhabit flagrant waters; the head black and glossy; thorax black except the margins; legs ferruginous.

Torquatus. Ovate tesselatus; head behind black. Marsh. 

The head is yellow; abdomen black; legs pitchy black. A British species.

Minutus. Ovate and black; wing-cafes and legs grey. Fabr. &c. 

Head pitchy, black and glossy; thorax at the sides pale; abdomen beneath pitchy black. Native of Europe.

Griseus. Above cinereous, beneath fulvous. Fabr. 

Size of the last, and inhabits Europe.

A small species found in Europe.

Lutusus. Fuscose; wing-cafes frirated with impressed dots. Marsh. 

A small species; the thorax is rugose, with transverse flexuous raised lines. Native of Britain.

Nittidus. Black and polished; margin of the thorax with the legs rufous. Marsh. 

Head and abdomen black. A small species found in Britain.

Piceus. Ovate, pitchy, and glossy; legs rufous. Marsh. 

Size of the last, and inhabits Britain.

Longipalpis. Black; feelers antenniform; antennæ and feet red. Marsh. 

Length rather more than one line; the feelers advanced and three-jointed, the first articulation long as in the antennæ of some curculionus; head black; thorax black and attenuated behind, line in front transverse and impressed; wing-cafes black and frirated with dots. A British species. 

Impressus. Black; thorax with a large impressed dot on each side; legs tesselatus. Marsh. 

Body entirely black; wing-cafes frirated. Inhabit Britain.

Antennæ fuscose; feelers tesselatus, with the tip black; head fulvous and dotted; eyes black; thorax fulvous and dotted, the front black; wing-cafes fulvous with longitudinal oblique lines of black; abdomen beneath black, covered with fine hairs; legs tesselatus and downy. Native of Europe.

Margipallens. Pitchy and entirely glossy; margin of the thorax pale. Marsh. 

A British species.

Ochrophorus. Black; sides of the thorax and wing-cafes, with a spot before each eye, lurid. Marsh. 

Length two lines; the head black, except the two lurid spots before the eyes; thorax and wing-cafes very finely dotted; thorax ferruginous. Native of Britain.

Inhabit flagrant waters in Europe.

Dorsalis. Fuscose; thorax green; wing-cafes frirated, tesselatus with a common black spot, including two tesselatus ones. Marsh. 

Native of Britain.

Cincindeloides. Black brassy; eyes prominent; wing-cafes with ridged frirae. Marsh. 

Body entirely black and brassy; head advanced; thorax with three hollows; wing-cafes with two lines of impressed dots between the ridges. A British species.

Pygmeus. Grey; head black behind; thorax yellowish. Fabr. 

A minute kind found in South America; the wing-cafes without spots.

Tricolor. Black; wing-cafes pitchy edged with black, and ochraceous at the tip; legs tawny. Herbst. 

Inhabit Prussia.

Cordiger. Black; wing-cafes and margin of the thorax ferruginous.
HYDROPHOBIA, in Medicine, from the Greek words, water, and fear; signifies, literally, a dread of water, or passion against water, liquid.

I. Feeble, as an objection to the above terms. Atropoia, or a dread of air, and pantophobia, or a fear of all things, as appropriate names for the disease, since the impression of cold air sometimes excited terror, and the disorder is marked by a singular degree of general timidity and dizziness. Others called it phobobiosis (fear of water), because the patient is thirsty, yet fears to drink. Several modern authors, however, objecting to an appellation expressive only of one symptom, have more correctly denominated the disease rabies, or rabies caninus, or canine madness. The French call it la rage.

It is uncertain at what period this disease became known. Its symptoms are never mentioned by Hippocrates, which affords a strong presumption that it did not exist in his time; or if it be a disease so singular and striking in its appearances, that it could never be seen by any one without leaving the deepest impression upon the mind. Aristotelis is the first writer who expressly mentions it. He says that all animals, even man, are infected by the bite of a mad dog, and destroyed by it. This imperfect state of his knowledge respecting the malady, is a proof that it was a matter of recent observation; for although several perfons might be bitten without suffering the disease, and, from the length of time which commonly elapses between the infection of the bite and the appearance of the symptoms, several cases might occur before it was referred to its true source; yet no very long time would be requisite to clear up these doubtful points. Accordingly, we find subsequent writers treating of the disease in a familiar manner. Plutarch affirms that the hydrophobia was first seen at Rome in the days of Alexandria. See Arisbt. Hist. Anim. lib. viii. cap. 21. Plutarch, Sympaathon, lib. viii. prob. 9. Le Clerc. Hist. de la Medicine, p. ii.

There is reason to believe, however, that the rabies, in the animal race, occurs at times spontaneously; but whether from the causes which have been stated by authors it was not easy to determine. Among these causes, Boerhaave enumerated "a very hot climate, or one exposed to the extremes of heat and cold; a very hot and dry season; feeding upon putrid, flinking, and maggoty flesh; want of water; worms bred in the kidneys, intestines, brain, or cavities of the nose (Aphorin. 1134.); but the influence of these circumstances in producing the disease is not established by a sufficient number of observations.

I. All domestic animals, birds, as well as beasts, are susceptible of the poison of the rabid dog. Indeed our experience has not yet taught us that there is any race of animals exempted from its effects. But whether every animal labouring under the disease is capable of infecting others, or whether this power is confined to a few only, we are yet to learn. Boerhaave affirms that the disease has been communicated by infection to others by dogs, cats, wolves, foxes, hares, aces, mules, fowins, apes, cocks of the poultry breed, and men, when affected with rabies (Aph. 1132.); and the cow has also been said to propagate it. Van Swieten has stated some instances, from old authors, of hydrophobia occasioned by the bite of an enraged cow wounding the hand and arm. But there is little doubt that, in fowl, the spasmodic and fatal disease, which ensued, was tetanus, and not hydrophobia.

II. This notion is confirmed by the early occurrence of the symptoms after the bite, namely, within the first or second day, which is not unusual in tetanic infections, but never perhaps occurs in hydrophobia. (See Van Swieten's Comment. on Aph. 1132. Alfo, Hamilton on Hydrophobia, vol. i. p. 109, 1d edit.)

It is certain, however, that not only animals of the canine species, but cats, have produced hydrophobia in the human species by their bite. Were we to judge from analogy, from facing two animals, so different from each other as the dog and the cat, capable of infecting others, we might be led to infer, that every animal susceptible of the disease had the power of communicating it, provided their natural habits led them to bite and tear with their teeth such animals as came in their way, while in an enraged state. With respect to men, under the influence of hydrophobia, although...
HYDROPHOBIA.

though the popular notion of their general disposition to bite those around them is erroneous, yet there are instances on record in which hydrophobic patients did bite some of their attendants, but no ill consequences have been known to follow. From this, however, as Dr. John Hunter judiciously remarks, we can draw no positive inference; for it is but a small proportion of such persons as are bit by dogs undoubtedly mad, who are infected with the poison. Traf. of a Society, &c. p. 350.

With regard to the activity of the poison of the rabid dog, the facts which have been collected have been as vaguely stated, and the inferences, therefore, are as inconclusive as those relative to the topics just mentioned. Among the older writers, indeed, there was much credulity, and they have transmitted to us many fabulous histories in regard to the operation of the rabid virus. "Sceare any poison known," says Hillard, (relying upon the truth of those tales,) "is so infectious, or so easily and readily communicated by so many and various ways as this of a mad dog is; for the slightest bite, only tearing the skin, without drawing blood; or the smallest quantity of the madding animal, either fresh or dried for some time, taken upon the tongue or lips; or rending a person's clothes and leaving the poison on the surfaces of the cloth, or by eating these, or by drinking the poisoned water of the maddening animal; or perishing by the poison, or by the wound itself, or by the bite of one who has been stung by a mad dog, as a woman had her collar torn by a mad dog, which she a considerate time after fewed up, and bit off the thread with her teeth, and some time after died rabid from biting off that thread. (Hildanus Offb. Chir.) Also a man only killing his children to take his leave of them when he had the rabies upon him, they all soon after died rabid. (Palamard de Morb. Contag.) Killing a favourite dog was what mad had the fame effect, &c. has produced this most fatal disease." (On Diseafes of Barbadoes, p. 249. See several similar cases quoted by Dr. Hamilton, vol. i. p. 98104.) Hillard admits, however, that the poison does not appear to infect a person through the unbroken skin; and there is certainly a defect of accurate detail, in the cases quoted by Dr. Hamilton, where the infection was said to have been communicated when no bite was inflicted. Some excoration or rupture of the cuticle may have existed, although unnoticed, in the hands of those who examined the mouths of dogs in this malady. (See Hamilton, cafe iii. p. 100, cafe ix. p. 103.) Where the disease was produced by a rabid dog, sticking a foare until it bled, we understand how the infection would be occasioned by absorption. See Dr. Hunter, in Transf. before quoted, p. 301.

As the bite only serves the purpose of inoculation, the danger arising from it will be various, as it happens to be inflicted in a part more or less vascular; or as the teeth are more or less loaded with the poison. There is the greatest danger from bites in the face, and the symptoms come on soont; bites in the hands also, which are generally bare, are full of danger. In other parts of the body, the clothing, by wiping the teeth of the animal, greatly lessens the danger of infection. It is fortunate that the human species is much less susceptible of the infection than the dog. Four men and twelve dogs were bit by the fame rabid dog, and every one of the dogs died rabid, while all the four men escaped, though they used no other means of prevention but such as we see every day to fail. There is also an instance of twenty persons being bit by the same mad dog, of whom only one had the disease. (See Dr. Hunter’s paper, p. 302.) Some writers have calculated, indeed, that, on an average, only one person in twenty-five, who are bitten by rabid dogs, suffer hydrophobia. Dr. Hamilton, however, on collating a great number of instances of bites received, found that the average did not amount to one; he thinks that not more than one in sixteen of the human species, who are bitten, take the disease. Loc. cit. vol. i. p. 31.

Some experiments, made by Mr. Cline, respecting the communication of rabies by inoculation with the salvia of a hydrophobic man, in the left flag of the diseafe, would throw great doubt on the infectious qualities of that secretion to the human subject. He took particular pains in inferring the salvia, while perfectly fresh, into a dog, three rabbits, and several fowls; but in none of these instances was there the least appearance of the disorder at the expiration of three months.—Mr. Ashley Cooper, on the other hand, inoculated a dog, a pig, a fowl, and a rabbit, with the salvia of a dog, which had recently died of rabies, by inferring, from the point of a lancet, between two and three drops under the skin of the inner part of the thigh of each. The dog and fowl were kept confined for nine weeks, and the pig seven, but without any appearances of hydrophobia. The dog afterwards became the property of a gentleman, who kept him nearly twelve months, and he had never any marks of the diseafe. The rabbit was accidentally killed on the fourth day from the experiment." See two cafes of Rabies Canina, by Dr. Babington, &c in the Medical Records and Researches, Lond. 1798, p. 136—8.

On the whole, therefore, the evidence is of an unsatisfactory and even contradictory nature, in respect to the qualities and operation of the virus of rabies; and much remains to be ascertained by future experiment and investigation. We know, however, too well, that the fatal consequences of the poison have appeared, in some instances, in which every practice had been adopted, after the infliction of the bite, to remove the bitten part, as well as every portion of the poison that could be supposed to lodge in the wound.

We should now have proceeded to describe the symptoms of the diseafe, as it affects the dog, in order that it might be speedily recognised, and distinguished from other diseafes, to which that animal is subject; but this has been already so fully and distinctly done, by a writer possessed of an extraordinary degree of experience upon the subject, that we must refer our readers to his description (see the article Dog); and proceed to give an account of the symptoms of the diseafe, as it occurs in the human subject. We may just remark, by the way, that the influence of names, in respect above all to the diseafe of the dog, has led to some dangerous popular mistakes, which are pointed out in the article just referred to. The term hydrophobia, being erroneously applied to the rabies of the dog, has induced a supposition that no dog is rabid, while he continues to drink; whereas he is constantly endeavouring to quench his thirst in that diseafe. And again, the appellation of madhefs has led to a belief that violence and fury are characteristic of rabies in the dog; but, though he is irritable and peevish, there is nothing of wildness in his disposition. In consequence of this mistake, dogs have been allowed to go about, fondled, and even slept with (see Mem. of Swedish Acad. 1777) in a rabid state.

History of Symptoms.—The wound inflicted by the bite of a rabid animal has nothing peculiar in its appearance, and heals as readily as the bite of an animal that is not rabid. From the time of the bite until the period when the symptoms appear, there is no derangement of health, nor any perceptible change in the constitution, provided the person bitten be not under the influence of fear. The interval between the infection and the commencement of the diseafe varies considerably in different instances: the most common period, as it was long ago stated by Celsius Aurelianus, appears to be about forty days or six weeks. Dr. Mendes states the
HYDROPHOBIA.

the ordinary interval at between thirty and forty days: (Mead on Poisons, p. 130.) and Dr. Babington from three to five weeks; some instances occurring much earlier, and others not for many months, so that he considers the average from four to twelve weeks. (Med. Records and Researches, before quoted.) In the cafes had before the Society for the Improvement of Medical and Chirurgical Knowledge, the interval varied from thirty-one days to seventeen months. Dr. Hamilton draws the following conclusions, as to the interval between the bite and the occurrence of the disease, from a table of 131 cafes. Only three took the disease before the 18th day, none before the 11th— from the 18th to the 30th, fifteen were feized: —sixty-three began to be ill from 30 to 59 days after the bite: — twenty-three were attacked from two to three months inclusive; — nine from three to four months; — two at five months; — one at five months and eleven days; — one at six months; — one at seven months; — two at eight months; — one between eight and nine months; — two at nine months; — one at eleven months; — one at fourteen months; — two at eighteen months; and one at nineteen months. (Vol. i. p. 113.) The last-mentioned interval is, he thinks, the longest to which any credit can be given. On the other hand, a cafe is related by Dr. Babington of Manchester, which proved fatal, as is usual; and every inquiry respecting which corroborated the patient's repeated affirmation, "that he had never suffered the least injury from any animal, except the bite, inflicted twelve years since, by an apparent mad dog." (See Memoirs of the Liter. and Philos. Society of Manchester, vol. iv. part ii. p. 431.) In this instance, the nature of the disease was perfectly clear, and the evidence as to the bite not falsifiable: so that we must either admit the latent state of the poison for this long interval, or the spontaneous origin of hydrophobia in man. Dr. Bardley's paper, which contains a reference to numerous cafes, in which the latent period of the poison was long, is worthy of perusal. But to proceed.

At an uncertain time after the infliction of the bite, the patient feels some degree of pain or uneasy sensation in the bitten part, which is sometimes compared to a throbbing by heart, and sometimes attended with itching, and sometimes supposed to be rheumatic. This pain, when the bite, as is most frequent, is in the hand, spreads up the outside of the arm to the shoulder, (not affecting the axilla,) and the neck. In some cafes the cicatrix left by the bite is said to become inflamed, and even to discharge. These pains are soon succeeded by a general depression of spirits, and especially a fever of an indefinable lightness and anxiety. Sometimes a general rigor or chill occurs, as in the commencement of a fever. The night is passed in the same reflexes, state, without sleep. The appetite begins to fail, and some thirst is present. And now the peculiar symptom which gives the disease its name, the dread of liquids, is discovered, often accidentally, on attempting to take drink; as the liquid approaches the lips, a sudden convulsive spasm, or catch in the breath, with a momentary sensation of choking, takes place, which is renewed at every attempt. As the disease advances, this attempt is not thought of without horror, and the very idea excites these spasmodic fits of choking in the throat, and catching of the breath. This may be best illustrated by examples. "On our proposing to him to drink," says Dr. Marret, speaking of a hydrophobic patient, "he started up, and recovered his breath by a deep convulsive inspiration; yet he expressed much regret that he could not drink, as he conceived it would give him great relief, his mouth being extremely parched and clammy. On being urged to try, however, he took up a cup of water in one hand and a tea-spoon in the other. The thought of drinking out of the cup appeared to him intolerable; but he seemed determined to drink with the spoon. With an expression of terror, yet with great resolution, he filled the spoon, and proceeded to carry it to his lips: but before it reached his mouth, his courage forsook him, and he was forced to desist. He repeatedly renewed the attempt, but with no more success. His arm became rigid and immovable, whenever he tried to raise it towards his mouth, and he struggled in vain against this spasmodic resistance. At last, flinging his eyes, and with a kind of convulsive effort, he suddenly threw into his mouth a few drops of the fluid, which he actually swallowed. But at the same instant he jumped up from his chair, and flew to the end of the room, panting for breath, and in a state of indefinable terror." (See Medico-chirurgical Transactions, vol. i. p. 138. Lond. 1809.) A patient of Dr. Bardley's, having eaten some bread and butter, with great difficulty, was requested to wash down this solid food with some liquid; and he expressed a readiness to make the trial. "On receiving a basin of butter-milk, he hastily applied it, with a determined countenance, to his lips; — when he was instantly feized with a fever and rigidity of the muscles of the neck, that he was compelled, in an agony, to defist from drinking. Shortly after, he raised himself upon his knees in bed, took the bowl again into his hands, and by forcibly stretching his neck forward, at the moment he received the liquid into his mouth, and then violently throwing his head backwards, he succeeded in swallowing a small portion. He appeared highly gratified by the success of this effort, and the fortitude he had exhibited; and exultingly demanded another draught of the butter-milk, as he now thought he could conquer the difficulty he had hitherto experienced. But a violent return of the spasms in the throat and neck checked this attempt. These convulsions were terminated by the stomach discharging the liquid previously swallowed, highly tinged with bile." (Memoirs of the Manchester Society, vol. iv. p. 439.) In a word, it is obvious to the byfarer, that every attempt to pass liquid over the root of the tongue excites convulsions in the larynx and pharynx, and even in the muscles of the cheek and abdomen; and therefore this symptom, the hydrophobia, as Dr. Mead and others have remarked, is not a delirium tremens, or hallucination of the mind, but a matter of experience, which at first excites the surprize of the patient. Mead affirms that it should have been called, not hydrophobia, but exsanguination, dyscataplasia, or difficulty in swallowing. (See his Mechanical Account of Poisons, p. 146, 3d edit.)

But the dread of swallowing liquids, although the most singular symptom of the disease, and the origin of its name, constitutes but a small part of this distressing malady. It is only one among many other effects of the poison upon the nervous system at large. The state of disease into which the nervous system is thrown, is evinced by the extreme irritability of the whole frame, mind and body; and the excessive susceptibility to all impressions; hence the constant watching and inquietude; and the sudden fits of anger and impatience, arising from the most trivial causes, as the patient himself readily allows, and even wonders at, and apologizes for, in the succeeding moments of composure. Hence also the delirium, and even the recurrence of his spasms, occasioned often by the slightest motion of the air, as from opening the door, from the approach of any person, or even of a person's hand, in front of him; from hearing water poured from one vessel to another; or even by the buzzing of a fly. This morbid excitability of the nervous system, is farther manifest in the extreme timidity and suspicion of

Vol. XVIII.
The patient, in the imaginary objects of terror and uneasiness, which the fevers frequently present to him, and in the occasional delirium and incoherence of ideas, from which, however, he early collects himself. The circumstances may be illustrated by referring to almost every case on record.

Dr. Bardwell, speaking of the patient before mentioned, says, "He was now alarmed to a degree of distraction at being left alone; he examined every object with a timid and suspicious eye; and, upon the least noise of a footstep in the gallery, he begged, in the most picturesque accents, to be protected from harm."—"I observed he frequently fixed his eyes, with horror and affright, on some ideal object; and then, with a sudden and violent motion, buried his head underneath the bed-clothes. The last time I saw him repeat this action, I was induced to inquire into the cause of his terror. He eagerly asked if I had not heard howlings and scratchings? On being answered in the negative, he suddenly threw himself upon his knees, extending his arms in a defensive posture, and forcibly throwing back his body and head. The muscles of the face were agitated by various spasmodic contortions—his eye-balls glared, and seemed ready to start from their sockets; and at that moment, when crying out in an agonizing tone—"Do you not see that black dog?"—his countenance and attitude exhibited the most dreadful picture of complicated horror, dilates, and rage, that words can describe, or imagination paint."—"His mental faculties at this period (a short time before death) suffered very little derangement; for although, when not attending to external objects, he would utter some incoherent sentences; yet, the moment he was spoken to, he was perfectly collected, and returned rational answers." (Bardwell, loc. cit.) Dr. Marcet observes, in regard to his patient, on the fifth day of the disease—"He appeared still coherent and distinct in his ideas; but some of his conceptions were considerably disturbed. His sight was not materially impaired, for he could tell what hour it was by looking at the clock; but he often fancied he beheld objects which were not before him. He thought, for instance, that he saw various insects and reptiles crawl about him. 'My sight is queer,' said he, 'I think I see strange animals.' &c. Once or twice he exclaimed with an accent of terror, 'Who is pouring cold water down my head?'—yet no one was near him. He was conscious of his extreme irritability, and often prayed to be kept tranquil. This unfortunate man, in the height of his dilates, still apologized for his acts of violence, and declared that he could not conceive what occasioned this extraordinary agitation."—Medico-chirurgical Transact. vol. i. p. 147.

These statements may convey to the reader some notion of the miserable condition of the sufferer, afflicted by this malady, and of its peculiar and characteristic symptoms; the impression of which cannot be easily effaced from the recollection of those who have witnessed them. There are some other circumstances belonging to the disease, of less note, which remain to be mentioned. One of these is a copious collection of a thick,ropy, and tenacious saliva in the fauces, which is often productive of extreme dilates; for as the miserable sufferer is unable to make the smallest attempt to swallow it, without exciting the convulsive choking, he spits it out incessantly, and with great vexation and difficulty, often cautions the bystanders to keep out of the way. "Oh! do something for me;" exclaimed Dr. Marcet's patient, "I would suffer myself to be cut to pieces! I cannot raise the phlegm; it flicks to me like bird-line." Dr. Wavell's patient, at times, drew the viscid phlegm from his mouth with his fingers, and with inconceivable rapidity and eagerness, threw it against the wall. The pulse in the beginning is not quick, nor is the skin hot; and there is none of the muscular debility so remarkable in fever; but as the disease proceeds, there is some feverish heat, and the pulse becomes quick, varying, however, exceedingly as slight causes of irritation influence the patient: as death approaches, it usually becomes very quick and tremulous. Sicknefs and vomiting often occur, when a little phlegm, tinged with brown or yellow bile, is brought up. There is often a feint of great oppression and stricture about the breast, or what has been called anxiety about the precordia, and which is probably an affection of the heart; for it is accompanied with sighing and deep irregular inspirations, and the patients find some relief from motion, as running and walking, which threw the lungs not to be the seat of the oppression. The countenance is generally sorrowful, and often expressive of a great degree of horror and dilates.

There is a considerable variety in the symptoms in different constitutions: even the hydrophobia, or dread of swallowing liquids, occurs in very different degrees. But there is no part of the disease that admits of greater variation than the degree of mental derangement, which in some does not amount to more than extreme irritability and impatience; in others to muttering and incoherent talking, yet giving rational answers when questions are asked; and in a few it rifes into short fits of the most violent rage and fury, in which the patients bite and tear themselves and every thing near them. In general they manifest no disposition to mischief; yet popular prejudice is still on the watch for the "barking and biting like a dog," as the disease advances. In the case related by Dr. Marcet, the bystanders confidently expected the symptom of barking, which they "thought at last to have clearly discovered in the peculiar noise which he made in breathing." Dr. Wavell, speaking of this fort of respiration, says, "the noise he made in drawing air into his lungs was undoubtedly peculiar; but neither in my opinion, nor in that of any other medical gentlemen who attended him, did it bear the least resemblance to the barking of a dog." (Med. Records and Researches, p. 151.) Were this notion of the canine metamorphosis, which the disease has been supposed to effect in man, merely speculative, it would be less important to concur it; but it is to be lamented, that the practical result of it, in the cruel and murderous plan of suffocating the patient, has been followed, both in France and in this country, within the last twenty years of the eighteenth century. See Hamilton on Hydrophobia, vol. ii. p. 140, and App. p. xxviii.

The duration of life, after the commencement of the symptoms of hydrophobia, has been on an average about four days; it varies from thirty-six hours to five, or even, though rarely, six days. The termination of life is likewise various in different instances: death is often very sudden, being produced by one of the convulsive attacks, such as occur on the attempts to drink; at other times, more general convulsions carry off the patient; while in other instances, again, the strength sinks suddenly, the patient becomes quiet and calm, and dies with a placid countenance, and without a struggle.

Dilates.—With the hope of acquiring some knowledge of the nature of this disease, and of the organs in which it is principally seated, physicians have ardently pursued the investigation of the changes of structure connected with it, by careful and almost innumerable dilations of those who have died of it. But it is to be lamented that no light whatever has been thrown upon the subject by these ample examinations. For, although in general some morbid changes in the structure of different parts has been discovered, yet these have been found in various organs, in different cases; those organs,
HYDROPHOBIA.

organs, which appeared to be the principal seat of disease in one instance, being found altogether in another, and vice versa; and the morbid changes observed in general, are by no means adequate to account for the phenomena of the disease.

The most frequent appearances which have presented themselves on dissection, have been marks of inflammation in the inner coat of the eustachian, near the ear, or upper orifice, consisting of red spots or blotches, or merely of an increased number of red vessels, with small streaks of red blood; in many cases a similar inflammatory appearance has been found in the pharynx, or upper part of the gullet, sometimes extending along the whole of that passage to the stomach. This state of the throat, æfophagus, and stomach, seems to afford an explanation, in some measure, of the pain and difficulty of deglutition, especially of liquids, which require a more active contraction of the passage; but the excessive dread at the attempt, and the convulsions excited by it, can only be ascribed to that peculiar state of irritability of the nervous sytem, which characterizes the disease.

On the other hand, however, cases of hydrophobia have occurred, in which no inflammation in those parts have been found. (See Dr. Babington's in Med. Records, &c. p. 144.) In some cases, a slightly fluid has been found in the stomach in considerable quantities; in others a dark bilious matter has been found to line its cavity. Hamilton, vol. i. p. 233.

Many dissections of persons who had died in a state of rabies are recorded, in which appearances of inflammation and great congestion of the blood-vessels were discovered in other viscera, especially in the brain and its surrounding membranes, and in the lungs. Sometimes not only an increased vascularity of the pia mater, the choroid plexus, and the brain itself has been found, but also flight watery effusions on the surface of the brain. A state of congestion in the lungs, resembling that which is discovered after a fatal peripneumony, has occurred in many instances to a considerable extent; and the vessels of the diaphragm have also been observed to be unusually turgid. (See Dr. Babington's cases in Med. Communic. and Med. Records, &c.—Mead on Poisons.—Ferrers's Med. Hift. and Reflections, vol. iii.)

Dr. Ferrers, indeed, is disposed to attribute much of the disease to this pulmonary derangement. "If future dissections should prove," he says, "that congestion in the lungs generally appears in those who die of rabies, I confess that I should be disposed to consider this disease as dependent on the obstrucion of the circulation in that important organ. Accumulation of blood in the head, and compression of the brain, must be the consequence of such an obstruction, rapidly formed. The quick panting respiration, anxiety, and sudden debility, may be referred to the same cause. In fact, we find a similar degree of tremor attendant on the group, which consists in inflammation of the trachea, and destroys by suffocation. That degree of inflammation in the stomach and æfophagus, which produces the difficulty of swallowing liquids, may not only arise from sympathy, but the symptom itself may occur in consequence of the state of the lungs alone." (Loc. cit. p. 34.) But in forming these conjectures, this intelligent physician has overlooked the circumstance, that, however rapidly such congestion may take place, in common peripneumony, no approximation of any of the symptoms to those of hydrophobia is ever seen to occur; and the peculiar affection of the nervous sytem is purely inexplicable upon any such mechanical grounds.

Some writers have described various derangements of the lower and other abdominal visceræ, which dissection has discovered, especially appearances of congestion or flight inflammation: Mead, Hillary, and others, have mentioned peculiar dryness of the pericardium, &c. But these changes appear to be accidental, and are more frequently not to be found. So that, on the whole, it would appear, that the nature of the malady is not manifested by any peculiar diforder of structure in any organ of the body, and therefore is beyond the reach of anatomical investigation.

Diagnosis.—From the peculiar nature of the symptoms above detailed, it might be conceived that no difficulty could occur, in distinguishing rabies canina from every other disease to which the human body is liable. But this is very far from being the case, as the records of medicine evince. For many histories are related, in which, although the disease was the consequence of a bite, it partook more of the nature of some other malady; and others are detailed, in which no bite had preceded the disease, or had occurred at so distant a period as to render its influence in exciting the disease extremely questionable: not to mention the number of mislakes which have been committed, in confecution of the symptom (hydrophobia, or dread of water,) being suppos't to be the offence, or pathognomonic symptom of the disease.

In many circumstances the tetanus bears a considerable resemblance to rabies, and has, doubtless, been mistaken for it. (See Tetanus.) This most violent and fatal disease is most frequently occasioned by flight wounds, especially about the hands or other tendinous parts; it seldom appears till after some little time has elapsed, and the wound has healed; it is marked by paroxysms of violent general spasms, beginning in the neck and throat, and accompanied by difficulty of swallowing, or total loss of that power; these spasms are excited by the slightest cau/es," for almost every attempt at motion, as attempting a change of posture, endeavouring to swallow, and even to speak, sometimes gives occasion to a renewal of the spasm over the whole body." (See Cullen, First Lines, vol. iii. chap. on Tetanus); and the disease generally proves fatal by one of these convulsions about the fourth day. In all these circumstances there is much similarity with those of rabies, inasmuch that some practitioners have denied the existence of rabies, as the result of the poison of a rabid animal; and contended that the disease is, in all cases, a tetanus, excited only by the wound which the teeth inflict. In some instances, it is from a view of the symptoms, it might be difficult to decide, whether the disease were tetanus or hydrophobia.

Dr. Bardley describes the case of a young gentleman, who, after having had his finger slightly wounded by a splinter of wood, was affected in about a week with spasms about the lips, locked jaw, and paroxysms of general spasm. On the third day after the attack he could not swallow any watery fluids. "Whenever they approached his mouth, the convulsive spasms of the face returned, and his head was forcibly drawn backwards." (Mem. of the Manchester Soc. vol. iv. p. 477.) The person who communicated this case, had formerly seen the same symptoms produced by the bite of a horse. Both these patients recovered. Similar examples of the occurrence of hydrophobic symptoms, arising in cases of local injury, are mentioned by Hildanus, Celsius Aurelias, and others.

It must be observed, however, that the tetanic spasms generally commence within a few days after the injury, or in a much shorter period than those of rabies; that the jaw is commonly rigidly locked in tetanus, and the muscles of the neck and back most particularly affected; that the spasm is of a more fixed or 'tonic' species, (in the language of Cullen) consisting of rigid and long-continued contraction, rather than of short convulsive action, and are relieved rather by remission of their violence, than by a complete
HYDROPHOBIA.

plete solution of the poison; that there is less feverishness, quickness of pulse, and thirst in tetanus; but, above all, that there is little of that extreme mobility of feeling, and anxious, impatient, and apprehensive state of mind, which marks the hydrophobic condition.

There is another disease, *hydrophobia*, which, in some of the many forms which it assumes, occasionally passes on a hydrophobic appearance. The leading symptoms of this disease are often of a violently spasmodic nature; and one of them, which has been considered as pathognomonic, the *glossus hydrophobicus*, consists in a spasmodic affection of the gullet; and is often connected with difficulty of swallowing. But the concourse of symptoms in hydrophobia, generally differs altogether from those of rabies, and could lead to no mistake, had not the error of regarding the *dread of water* as the essence of that disease been adopted. In consequence of this error, and the improper application of the term *hydrophobia*, as the name of the disease, extreme confusion has occurred in the history of canine madness.

Thus while some physicians, misled by this name, have described cases of *spontaneous* hydrophobia, i.e. hydrophobia arising without any obvious exciting cause; others have referred the origin of this disease to various causes, altogether different from each other. Dr. Rush, for instance, enumerated twelve causes of hydrophobia, besides the bite of a rabid animal; among these are cold night air, worms, eating beech nuts, great thirst, fear, hydrocephalus, and typhus fever. (See Med. Inq. and Obs. vol. v. p. 213.) The truth is, that the symptom *hydrophobia* is so far from being peculiar to canine madness, that it occurs in a number of other diseases; and, on the other hand, it is in some cases feared to be actually present from the true rabies. A fatal case of canine madness is related by Hildanus, (p. 365. Observ. 88.), in which there was no hydrophobia. And three cases of the same nature are mentioned by Dr. Mead. (On Poisons, p. 147.) But the number of disorders in which a difficulty of swallowing, and a concomitant hydrophobia, occurred, is very great. Mead, Morgagni, Plater, and others notice it accompanying hydrophobia. "I have known it," says the first named physician, "in the height of a violent hysterical disorder, to have continued for many hours, till the convulsive motions in the throat were quieted by proper medicines; and I remember a case, in which fits of a palpitation of the heart were attended with so great a degree of it, that it seemed not to differ from the true hydrophobia." (Loc. cit.) Boerhaave used to mention an instance of it accompanying a fever occasioned by heat and fatigues, joined to the abuse of spirituous liquors. It has been observed connected with various inflammatory and spasmodic affections of the throat, gullet, and stomch. Thus Sauvages quotes one case, where it supervened to typhus; and another, where it accompanied the various fatal throat. (See Nofol. Method.) But the most remarkable cases of this nature are to be found in the Edin. Medical Essays, (vol. i. p. 222 and 227,) in which hydrophobia was produced by unusual irritation in the stomch, without the most extreme fulmination of rabid poifon. In one of these cases there was violent inflammation of the stomch, the patient frequently spouted saliva from his mouth, and had all the horror at the fight of water, which occurs in cases of true rabies, where the difficulty of drinking has been experienced. Both these perons recovered. (See GASTRITIS.) The symptom hydrophobia, or *dread of water*, has also accompanied pleurisy and peripneumony (see Ferrier’s Med. Hist. and Refl. vol iii. p. 24—26.) and the writer of this article once faw it connected with St. Vitus’s Dance.

But farther, this symptom, the dread of liquids, unconnected with rabies, does not always arise from local irritation; it has been brought on by violent affections of the mind, in irritable and delicate habits, and terminated fatally. (See two cases from Plater and Sauvages, quoted by Dr. Bardley, in Manch. Trans. vol. iv. p. 470.) Dr. Percival has remarked, that it has sometimes been brought on by the imagination alone; and Dr. Ferrier, in illustration of this remark, says, "I met with an instance of this kind lately, in which it was very difficult to prevent a person from rendering himsel th completely hydrophobic. Himself and his wife had been bitten by a dog which they supposed to be mad. The woman thought herself well, but the man, a meager hypochondriac subject, fancied that he had been bitten by his horse, and that he could hardly swallow anything. When he first applied to me, a medical friend who was present, asked him whether he had any sensation of heat at the pit of the stomch. He answered in the negative, doubtfully; but, next day I found him in bed, complaining of *it*. It was a pit of the stomch, difficulty of swallowing, tremors and convulsion in the head. He continued to persuade himself he was ill of rabies, and confined himself to bed, expecting death for near a fortnight. At last I remarked to him, that persons who were attacked by rabies never survived more than six days; this drew him out of bed, and he began to walk about. By a little indulgence of his fears, this might have been converted into a very clear case of *spontaneous hydrophobia*, and the patient would probably have died."

The use of the appellation hydrophobia, then, deduced from a single symptom, which belongs to a variety of diseases, evidently tends only to mislead, as the respectable physician just quoted remarks, by diverting the attention of practitioners to supposed analogies, which have no other foundation than the abuse of a word. To be correct, we must prefer the different between rabies, and diseases which are essentially different from it in their usual appearance, and which only acquire an adventitious resemblance to it under uncommon circumstances. We may, therefore, reasonably question the existence of such a disease as *spontaneous hydrophobia*. "If those cases be analyzed," Dr. Ferrier remarks, "they will be found to belong to the class of hysterical, febrile, mental, or spasmodic disorders, and by ranking them under their proper titles, we shall at once clear this subject from a great and accumulating mass of error. By considering the matter in this point of view, we are also enabled to explain the contradictory reports hitherto so perplexing, on the effects of remedies in rabies. It is easy to perceive, that evaccin and antispasmodic remedies would remove a difficulty of swallowing, occasioned by inflammation or poifon in the stomch or a€p”?gaphus; that bark and wine would cure it in cases of typhus and low mania; and that opium and the cold bath would be successful, when it is accompanied by tetanus." (Vol. iii. p. 30. See also Hunter, in Tran. of a Society, &c. p. 203.) Mead on Hydrophobia, p. 6—11.

Prevention and Cure.—As no remedy has been discovered which has any effect in the removal of this extraordinary disease, when its symptoms have commenced, the means of prevention have ever been deemed objects of the first importance. For this purpose numerous prophylactics have been proposed from early times, and many are in general use, which are supposed to counteract or expel the poison, by their effects upon the constitution. Notwithstanding, however, the testimony of discerning physicians, expressed in terms of the greatest confidence, in favour of particular preventive medicines; upon fairly weighing the proofs of their efficacy, not one appears entitled to the smallest credit. It
HYDROPHOBIA.

It will be almost sufficient to enumerate the remedies which have been suggested for this purpose, without any comment. The absurd jumbles of thence, whether old or new, Mead admits to be unworthy of notice; and from this censure we cannot except the athes of river claw-fish, burnt alive upon copper, which Galen and Dioscorides aver to be invariably successful; the roasted liver of the mad dog; the sponge or excrescence of the dog’s nose; the famous aromatic opiate of Scrophuous Largus; the powder of tin with mithridate, fo extolled by Mayriner, Gree, &c.; nor even thelichen cinerous, (ash-coloured holt-wort,) or the pulpia antiflus (compounded of this lichen and pepper,) which Mead himself introduced into the paraphernalia of the London college, and which he affirms he had never known to fail of success, though he had used it a thousand times. (See Mead on Poisons, p. 158 et seq.—Boerhaave, Aphorism 11. 7, with Van Swieten’s commentary.) So confident, indeed, was that learned physician in the powers of this drug, that he affirms, “I have often wished, that I knew a certain remedy in any other disease!” Another preventive, which was introduced from China by Dr George Cobb, and has been called the Tonguin medicine, has been equally extolled as an infallible prophylactic: this consists of large doles of mugik and native cinna bar. The Chinese give it in the dose of sixteen grains of mulk, conjunct with a ferule of native, and the same quantity of facetious cinnumar, whole, if it fail to procure sleep and sweating, is repeated in three hours. (See Hillary on the Diff. of Barbadoes, p. 266.) But this medicine, like the preceding, has been found to fail altogether. There is another pretended specific, which claims our attention chiefly because it flood high in reputation for many years, and is even now scarcely laid aside: this is the famous Oranghick medicine, prepared by Mr Hill of that town. It has been too clearly proved, however, that this medicine is incapable of preventing the accession of rabies in persons bitten by rabid dogs. Dr. Fothergill was among the first to represent, from a very clear cafe. (that of Mr. Bellamy, Med. Obf. and Inquiries, vol. v. art. 19.) that its virtues were not equal to its reputation; and other cafes have subsequently occurred, in which the disease ensued and terminated fatally, notwithstanding the fullest use of the medicine. (See Dr. Babington’s cafe in the Med. Records and Researches, Hamilton, vol. i. p. 165, &c.) Indeed, if the analysis of Dr. Heyham, which was repeated by Dr. Black, and correct, it would seem pretty evident a priori, that this celebrated Oranghick nostrum could not possess any active properties; its principal ingredient being cakal! From the analysis of this eminent professor and his pupil, the whole composition is as follows; namely, half an ounce of powdered chalk, ten grains of alum, three drams of Armenian bole, one dram of the powders of cecampone root, and fix drops of the oil of anise. (See Heyham. Diff. Inaug. De Rabie Canina, Edin. 1777.) After the failure of so many medicines, which have been reputed infallible, and after such men as Dr. Mead could be deceived into the belief of such infallibility, the writer of the article Dog, in this work, must expect that another “specific“ will be received by most readers with a great degree of scepticism, notwithstanding the number of experiments which he alleges in its support. This remedy consists of a decoction of the fresh leaves of rue and of the tree-box, of each two ounces, and of sage half an ounce. He avers that this medicine was given to ninety animals, of which only one went mad; and that about forty human persons have taken it, of whom none suffered the disease. But we are disposed to fear that this will be found liable to the same censure which is applicable to all the rest.” “No one of them,” to borrow the words of Dr. Rush, “has, I believe, done any more good, than the boiled species which have been used to eradicate the goat or cure old age.”

But how, it will be asked, have these medicines obtained the credit which they have for a long time possessed? Probably, from some of the following circumstances attending the bite. 1. The animal may have been enraged, but not diseased. 2. He may have been diseased, but not rabid. There is no doubt that the defiquer, and other febrile disorders of dogs, have been mistaken for rabies. (See a paper of Dr. Jenner’s on this subject, Medico-Chirurg. Transf. vol. i. p. 236.) 3. The saliva, when infectious, may have been wiped off the teeth in passing through the clothes of the person bitten, as not to have entered the wound. This rendered extremely probable by the circumstance that bites in the face have been most frequently followed by hydrophobia. But 4th, and above all, it is now a well ascertained fact, that those who have been bitten by dogs, actually rabid, a very small number have been afterwards feized with hydrophobia, whatever treatment was adopted, or even when nothing whatever was done with a preventive view. It may be added, however, that, as mental impressions often both excite and cure hydrophobic symptoms, and especially the feverish incipient symptoms, so any of these nostrums, in which the patient placed confidence, would remove those imaginary threatenings of the disease. See Dr. Percival’s Letter to Dr. Haygarth, in the London Med. Journal for 1789, vol. v. p. 300.

We are induced to notice another prophylactic, chiefly from the antiquity of its origin, and the general credit which it obtained even to recent times: this is the employment of cold-bathing. Celsius first mentions this remedy; but recommends it principally as a cure; and apparently upon theoretical principles, though he calls it unicum remedium. (De Med. lib. v. cap. 27.) For, as the patient both desires liquids and fears to drink, he advises that he be thrown unawares into a fish-pond; and, if he cannot swim, that he be bucked several times and taken up again, and, if he can swim, that he be forcibly immersed, and compelled to swallow water, “so that his thirst and dread of water may be cured together.” From this absurd notion, apparently, the practice of half-drowning persons bitten by rabid animals, in modern times, has arisen: but ample experience has demonstrated that the practice is not less frivolous than the theory upon which it was built; and among those who have undergone the operation of immersion, whether by mere dipping, or to the extent of “drowning and recovering by turns,” as Mead calls the ancient practice, an equal proportion have been from the mode of treatment. Notwithstanding the inefficacy of all the alleged antidotes to the poison of a rabid animal, there still remains a method by which it is probable that the occurrence of hydrophobia may be effectually prevented; this consists in the local treatment of the wound occasioned by the bite. As the subsequent malady originates from the operation of the poison, introduced with the salvia of the rabid animal, any expedient by which the poison could be destroyed or removed, previous to its operation on the constitution, would of course secure the individual from its effects. Upon this principle, the ancients recommended the enlargement of the wound by incision, the application of a cupping-glass, and of the actual cautery, and the maintenance of a discharge for many days, (see Celsius, lib. v. cap. 27. Galen, de Thcr. lib. i. cap. 15.) a practice which has been followed by more modern practitioners. Hildanus Obf. Cent. i. Obf. 87. Mead, loc. cit. p. 156.
HYDROPHOBIA.

In order to fulfil this indication by the local treatment of the wound, the following points appear to deserve attention: 1st. The removal of the poison by washing the parts simply; 2dly. The destruction of the part by cautery; and, 3dly. The excision of it by the knife. The first measure, or ablation of the wound, has been strongly recommended by Drs. Haygarth and Percival, to be commenced immediately after it may have been inflicted. The practice is safe, and may possibly be beneficial, when thus early resorted to; it may also be advisable, where the wound has been inflicted in the face, near the eye, or near some large blood-vessels; or where the patient refills all application to submit to the knife; or where there may be a little probability of the madness of the dog, as to render it unjustifiable to subject the patient to present pain, and future deformity. (Percival, in Lond. Med. Journal, vol. x. p. 308.) This washing, however, must be conducted with the most persevering attention, in bad cafes, for several hours, first by an abundant effusion of cold water, and afterwards of warm water; “a continued stream of it, poured from the spout of a tea-kettle, held up at a considerable distance, is peculiarly well adapted to this purpose. If the canine poison infused into a wound were of a peculiar colour, as black like ink, we should all be aware that plenty of water and patient dilution would effectually wash out the dark dye; but this could not be expected by a flight and superficial ablation.” (Haygarth, ibid. p. 297.) Whence Dr. Haygarth advises the plan of colouring the wound with fulmar tinged with ink, after it has been carefully washed; and, after a few hours, to wash out the stain; by which we obtain a sort of ocular proof of the complete ablation. Dr. J. Hunter remarks, that as there may be cafes in which innumerable objections to more effectual steps may render this method worthy of trial, it would probably be more successful, if, after washing copiously with cold water, the caustic alkalai was to be added to the water, in such proportion as the part could easily bear, and the washing to be continued with this for some time. Tranf. of a Society, &c. before quoted.

The same author observes, that cauteries may be admissible in some cafes, when the knife cannot be used; and though they have failed in certain instances, yet that was probably owing to their not having been applied to all the infected surfaces; and he suggests the propriety of employing for this purpose the caustic vegetable alkalai in a solid form, because it acts more speedily, and also more completely destroys and dissolves all animal substanies. It appears that this caustic substance has actually been employed for many years by Mr. Simmons, and the other surgeons at the Manchester infirmary, with uniform success; in upwards of forty cafes, in which Mr. Simmons applied the kali purum, or caustic potash, to the bitten parts, no hydrophobia ensued. Ferrar’s Med. Hist. &c. vol. iii. append. p. 221.

The only certain means, however, hitherto employed as a preventive of the disease in question, are to be found in the excision of the parts wounded; and, therefore, whenever the parts can be cut out, it ought always to be done. This operation must be performed with a bold hand, and the utmost care must be used to effect the removal of every part with which the dogs teeth may have come in contact; for the smallest portion left might produce the diseafe. It becomes, therefore, necessary for the operator to examine accurately every portion of the wound, and to ascertain to what depth, and in what direction, the teeth may have penetrated, keeping in his mind the situation of the parts in the act of biting, in which the skin and flesh are pinched up, and therefore put out of their natural position, before the teeth penetrate them. He should again cautiously examine the wound, after the

excision has been made, in order to ascertain that every part lacerated by the teeth has been removed.

An important question here arises, in regard to the period after the bite, at which the operation of excision may be performed with security to the patient. This can only be solved after a long and cautious experience, which, on this subject is rendered uncertain and difficult to be obtained, by the numerous failures of the poison to excite the diseafe, independently of any preventive measures. And, in a theoretical point of view, it may seem to involve another question, which has been much discussed; namely, whether the poison produces its deleterious effects on the constitution, in consequence of being taken up by the absorbents, and carried into the circulation; or whether it acts merely upon the extremity of the nerves of the part, and through the medium of them influences the rest of the nervous system. Such a question, however, is perhaps beyond our decision, and is not necessarily connected with the practical one previously stated. We may just mention, that, in the case related by Dr. Marcet (Medico-Chirurg. Transf.), in one of those described by Dr. Babington, and in another, detailed in the Medical Communications, vol. ii. the pain, originating in the bitten part, at the commencement of the hydrophobia, seemed to follow the course of the nerves, rather than that of the absorbents, and was not connected with any affection of the axillary glands, in the two former cafes, in which the bite was in the hand, nor of the inguinal glands in the latter, where the bite was in the leg. Mead imagined that, as the poison “immediately affects the nervous liquor, the mischief must have taken place before any applications of this kind can be made.” But while, on the one hand, we have instances on record, in which the excision was performed with success many hours, and even four or five days, after the bite; so we observe, on the other, that the poison appears to lie long dormant in the part, and only to affect the system, after the new inflammation or pain occurs, which gradually extends to the centre. Whence the most rational conclusion appears to be, that, as the diseases communicable by inoculation, that is to say, by the local application of the infection or poison producing them, there is a specific period, prior to which the disorder may be at any time prevented, by the removal of that part where the matter was at first introduced. “(Med. Records and Researches, p. 127.) See also Mémoires de la Soc. Roy. de Médecine de Paris, where there are many instances of local treatment being effectual in preventing the disorder in question, at the expiration of many days.

An account of the treatment of hydrophobia, when the diseafe has already appeared, will not occupy much of our attention; as it must be a mere enumeration of fruitless expedients, and of medicines altogether delusive even of palliative influence. Nevertheless, it is well that we should be acquainted with the unsuccessful indications, which different practitioners have heretofore pursued, and with the active agents, which they have diligently, but in vain, employed; in order that we may not be occupied in useless repetitions in future. The want of preconcerted method, indeed, in investigating the cure of this disease, is very apparent in most of the writers on the subject, and is probably one of the principal
principal causes of the little progress that has been made in that important inquiry.

Among the various articles of the Materia Medica, that have been administered to persons affected with hydrophobia, opium would seem, from analogy, to be peculiarly adapted to relieve the symptoms; especially the extreme irritability of mind and body, the complete loss of sleep, and the convulsions. Accordingly it has been administered in various forms, in some cases, to an extent that is scarcely conceivable a priori, and yet without having been found to do any evident good. In a case related by Dr. Vaughan, fifty-seven grains of solid opium were taken in the course of fourteen hours, in addition to half an ounce of liquid laudanum, which was injected in an enema; in another instance, attended by Dr. Wavell, four grains of opium were swallowed every hour, until fifty-four grains had been taken, besides ten grains in an enema; and in a third, under the direction of Dr. Babington, the enormous doses of twenty-five grains, and half a draught of solid opium, were repeated at short periods, so that in eleven hours no less than a hundred and eighty grains of opium were taken without any benefit, and even without producing any sleep. (See Med. Reports and Researches.— Vaughan on Hydrophobia, Meafe on the same, &c.) After such evidence of its inefficacy, we may almost affirm, with Dr. J. Hunter, "that it can only be imputed to the want of method and order above-mentioned, that this medicine still continues to be given in almost every case of this disease."

Blood-letting has been a favourite expedient from the earliest records of the malady, and has been frequently employed to a very great degree. Boerhaave considered the disease as highly inflammatory, and Mead suggested the use of early and copious bleeding, till fainting was produced; Fothergill, and others of a later time, employed it freely, and Dr. Ferrier, deeming an inflammatory congection in the lungs an essential part of the disease, as well as a similar condition in the contents of the cranium, says that "blood should be drawn from the jugular veins, and perhaps the head and lungs would be best relieved by the repetition of bleedings." Dr. Nugent's case is quoted as an example of the efficacy of blood-letting in the disease; but that case is a questionable example of rables; and both from the series of preceding symptoms of declining health and spirits, and from the course of the disorder itself, appears to be rather referable to hysteria than to rables. In one of the cases, described by Dr. Babington, blood-letting was practiced without the smallest benefit; and in the other it appeared to do harm.

Cold bathing, or the affusion of cold water over the body of the patient, has been frequently employed as a curative, as well as a preventive measure. Celsus recommended it only when the hydrophobia had appeared; and Van Helmont affirms, that he cured an old man by submersion in salt water, (Ortus Medicina.) But in the hands of Boerhaave, Mead, Vaughan, and many others, this expedient has been as iner as any of the preceding. (See Mead, loc. cit. p. 173. 182. Hamilton, vol. ii. p. 14.) In tetanus the cold affusion has of late been found beneficial; and it is probable that the spasmodic affections, cured in this manner, were of a tetanic nature, and not rables.

The warm bath has proved equally inert; and the free administration of mercury, both internally and by fricion, has evinced no greater powers. The use of oil, which was recommended by Celsus and Celsius Aurelianus, and fuggelled more strongly from its beneficial effects in cases of poisonous bites inflicted by insects and reptiles, was revived a few years ago by Dr. Shadwell, of Brentwood (see Memoirs of the Med. Soc. of London, vol. ii.) and it has been employed in the way of a bath, by fricion, and also taken internally; but it has proved altogether inert, and some patients, immersed in an oil bath, have appeared to have their sufferings increased. (See Hamilton, vol. ii. p. 54. 56.) In one case, indeed, the patient is said to have recovered but not strictly according to the ordinary appearance and brevity of hydrophobia. The employment of various antispasmodics, as camphor, ephedrina, cafior, &c.; of the metallic tonics, as the oxyd or flowers of zinc, the cuprum ammonium, &c. (largely administered in Dr. Vaughan's cafes); and of sudorifics and diuretics, (see Mead.) of vinegar, of caustarides, of blisters, and rubefacients, has been attended with the same failure as that of the medicines already detailed.

Such being the inadequacy, then, of all the expedients hitherto adopted for the cure of rables, and such the difficulty of acquiring any accurate notion of the nature and seat of the disease, even by the most accurate anatomical investigation, we acknowledge ourselves altogether unable to fuggel any system of treatment, which might be particularly worthy of trial, in future cases of the disease. Dr. John Hunter proposes a trial of arsine, which is the principal ingredient in a pill, used in the East Indies, and said to be a specific against the poison of serpents, and also against the bite of a mad dog. He also fuggels the probability of diminishing the effects of the poison, (which is apparently confined to the part bitten, until the symptoms actually begin,) by making numerous and deep lacerations where the wound was, and applying cupping glaftes repeatedly; by using ligatures; or by applying ice or a freezing mixture to the part, so as to benumb it, and to arrest for a time all motion, and of course that of the absorbent vessels. Dr. Rush believes, that "the disease produced in the human species by the bite of a rabid animal is a malignant fever," and that the same disease, which exists in its course, is the result of inflammatory action, and to be removed only by early and copious blood-letting, according to circumstances of the case, the strength and age of the patient, the state of the pulse, &c.; and Dr. Ferrier has, like Dr. Rush, experienced a similar change in his opinions, both of whom have originally considered the debility as primary, and not as the result of increased excitement; and both have decided to treat future cases of the disease upon that principle, by depletion, and evacuants.

HYDROPHORIA, formed of ωιδος, water, and ίσης, I hear, in Antiquity, a feast, or funeral ceremony, held among the Athenians, and people of Ægina, in memory of those who perished in the deluge of Deucalion and Ogyges.

HYDROPHTHALMIA, from ωιδος, water, and ισης, the eye, signifies in Surgery, a morbid enlargement of the eye, arising from a preternatural increase in the quantity of the aqueous and vitreous humours.

In certain cases, it is the aqueous humour which collects in this manner, and then the disease is principally situated in the anterior and posterior chambers of the eye. In other instances, the vitreous humour is chiefly concerned, not merely accumulating in a preternatural degree, but also in general losing its wonted consistence, and becoming thinner and more watery. In the commencement of the disorder, the patient experiences no complaints, excepting a sense of tension about the eyeball, a kind of stiffness when the organ is moved, and a diminution in the acuteness of vision. The globe of the eye by degrees acquires a flat, in which its enlargement is quite manifest, its feel harder than natural, the pupil diluted, the motion of the iris feeble, the impairment of sight much more serious, and the painful sensation of tightness about the affected organ a great deal more distressing. At length, the eyeball attains such magnitude, that it projects out of the orbit, and the patient is afflicted with complete blindness.
HYDROPHTHALMIA.

The pain now becomes excessively severe, extending all over one side of the head, and frequently affecting the teeth, so as to disturb the patient's rest day and night. As the eyelids can no longer be closed, the tears fall over the cheek, and the friction of the eyelashes against the eye make this latter part inflame and ulcerate. The cafe, when it has made such progress, affords confiderable difficulty to be cured. It frequently happens that the anterior chamber of the eye is observable, and the iris, instead of being at a greater distance than usual from this membrane, is often approximated to it.

We are then to understand by the term hydrophthalmia, a dropical enlargement of the eye, and not a swelling, or protrusion, of this organ from other caufes, a cafe to which surgical writers affign the name of exophthalmia. See EXOPHTHALMIA.

No doubt, the caufes of the dropy of the eye are as numerous as thofe which give life to the fame difeafe in other parts of the body. But, even the most credulous writers are willing to own the difficulty of ascertaining it in a clear and satisfactory manner. If we can trifl the afertions of Richter, all the known caufes of hydrophthalmia have the immediate effect of interrupting the due abforption of the humour of the eye, and act in this manner, either by producing obftuction, weaknefs, or irritation. The celebrated ocufult, Japius, fancied, that in the healthy flate there was a continual excretion of the aqueous humour through the pores of the cornea, and that the dropy of the eye was principally owing to a clofe of thofe pores, and a confequent ftropage to the exudation of the above mentioned fluid. Scarpas, in critificking this opinion, maintains, with much reafon, that its adherents evince their imperfeft acquaintance with the activity of the absorbent sytem in the animal economy. Bedefes, as Richter has well obferved, the cornea in many cafes of hydrophthalmia, retains its tranparently, and is to all appearances free from difeafe; while, in the leucoma, where it is completely opaque, infolated, and thickened, and where, in all probability, its pores are entirely imperforoius, we find not the leaft tendency to hydrophthalmia.

The dropy of the eye is very difficult of cure, and, indeed, frequently incurable. When the diforder has once made fuch progress, as to have entirely deprived the patient of fight, the cafe no longer admits of a complete recovery. Nothing can be more obvious, than the imposibility of rectifying the injury, which the interior parts of the eye muft suffer from much dilatation; and hence, if a perfect cure can ever be efpected, it is only when the ufgeone has it in his power to hinder the excefsive enlargement of the eyeball. The difeafe may even increase in fuch a degree as to prove fatal. (Louis, Mem. de l'Acad. de Chir. tom. 5. Terras, Journ. de Médecine, tom. 45.) In cafes of this aggravated difeafe, the bones of the orbit are in general cavious. A radical cure of hydrophthalmia is reckoned a very difficult thing to accomplish, for, when the complaint has been removed it generally returns, and the relapses are not easily prevented. The cure is equally difficult, whether the difeafe be chiefly occasioned by the aqueous, or the vitreous humour.

In the treatment, it is an indication of the highest importance to trace, and remove the caufes of the difeafe. This is the only way to effect a radical and lafting cure. In proportion as the caufe is removed, the preternatural accumulation of fluid in the eye spontaneously diminishes, and does not take place again. Authors inform us, that the fame caufes, which produce dropy in other parts, may also produce it in the eye. However this may be, certain it is, that practitioners are seldom enabled to ascertain the caufe of the complaint with precision, and they are, therefore, compelled to treat the cafe on empirical principles. We learn from Scarpa, that hydrophthalmia is sometimes preceded by blows on the eye, or adjoining temple; sometimes, by an obfinate internal ophtalmia; that, in certain inanities, it is preceded by no inconvenience, except an uneasy fentiment of tumefication and dilatation in the orbit, a difficulty of moving the eye-ball, and an impairment of fight; and, lastly, that it is occasionally preceded by none of these caufes, and no other manifest one whatever, especially when the complaint occurs in young children, from whom no information can be obtained.

The furgeon, who acts empirically, merely endeavours to procure a diffipation, or removal, of the preternatural accumulation of fluid, and though he afterwards generally employs tonics to obviate the weaknefs, which he supposes to have been produced in the eye by dilatation, and to be likely to bring on a return of the difeafe, yet, as he does nothing towards the removal of the original caufe, he seldom succeeds in preventing a relapse.

The internal remedies, which have been administered with a view of difipating the redundancy of fluid in the eye, conftit of emetics, purgatives, diaphoretics, and diuretics, and the felection is regulated by the particular constitution of the patient. Sometimes one class of medicines have powerful effects, while the operation of another is quite inefficacious; and a short trial of the various kinds will soon inform the skillful furgeon which ought to be preferred. Nitre and squills, juniper berries in powder, or decoction, &c. are mentioned by authors as proper diuretics. The digitalis purpurea is alleged to have proved beneficial. With regard to purgatives, the kali tartarizatum is said to be the bell in the generality of infancies. In obfinate cafes, emetics are frequently of confiderable service, and, even when unaided by other means, often difipate the fluid collected in drofical difeases. They also not unfrequently promote the efficacy of diuretics and purgatives, and the latter remedies, after appearing to be inefficual, are often rendered productive of the defired effect, by being preceded by emetics.

When none of the foregoing medicines answer the purpofe, refolevts may occasionally be prefcribed with advantage. Mercurial and antimonial preparations are particularly recommended. The proper plan is to give them alternately with doses of purgative and diuretic medicines. The patient may take a grain of calomel, ten grains of ciusa in powder, and a grain of fulfur auratum antimonii. When there is any reafon for suppefting that the dropy of the eye is owing to an irritation, acting on that organ, opium, calomel, and faffron are recommended, in conjuncHon with evacuants. When debility is thought to have a share in bringing on the difeafe, bark, floop, and aromatic bitters, may be ordered together with diuretics.

Besides these internal remedies, several topical means have been tried, for the purpose of promoting the abforption, or difpersion of the redundant fluid in the eye. 1. Differs applied either behind the ears, or over the eyebrows, and kept open a confiderable time. 2. Iffues and fetons in the arms, or nape of the neck. 3. Sternutatories. Richter mentions an infaluation of inveterate hydrophthalmia being cured in a few days, by the patient introducing every now and then into his noftrils a kind of snuff thus composed;
hellebori albi gr. x. herb. majoran. 9r. nisue. 4. Electricity sometimes appears to have done good. 5. Bathing the eye with ointment collyria was recommended by Janin, under the idea, that this method would tend to open the pores of the cornea, so as to let the aqueous humour exude. 6. Spirituous and ammninous vapours to excite the action of the absorbing of the eye. 7. Applications, containing thorn, muriate of ammonia, &c.

It is not to be dissembled, that, in the treatment of the present distemper, all internal and external remedies are, for the most part, quite unavailing. Scarpa acknowledges, that he has never yet met with a single well-detailed histor of a dropsy of the eye being cured by such internal medicines as are most recommended by the best surgical authors. With regard to externals, he has learnt from his own experience, that when the edema is manifest, afflament and corroborant collyria, as well as compreession of the protuberant eye, are highly prejudicial. In this circumstance, a fetic in the nape of the neck, bathing the eye in a lotion of mallows, and applying a plaster composed of this plant, has enabled him to calm, for a time, the ten and painful sensation generally experienced in the orbit, and about the temple and forehead. But Scarpa affirms us, that as soon as the eyeball begins to project from the orbit, beyond the eyelids, there is no means of opposing the grievous dangers, likely to be induced by the diffuse, except an operation, which consists in letting out the superabundant humours of the eye by an incision, and afterwards causing the interior of the organ to inflame and suppurtate, so that the eye may gradually shrink within the orbit, and heal. Were the operation deferred, the patient would be left to suffer frequent attacks of opthalmia, and to run the risk of ulceration taking place in the eyeball and subjacent cheek: nay, what is worse, the disease is liable to degenerate into carcinoma.

The operation, which, until lately, has been generally advised for the relief of hydrophthalmia, is, as has been named, paracentesis ocu!la. When the aqueous humour is supposed to be too abundant, certain authors direct us to puncture the cornea, at a little distance from its edge with a lancet, or cataract-knife. When the vitreous humour is principally concerned in the disease, they tell us to proceed in the extraction of the cataract, divide one-half of the cornea, open the crystalline capsule, and press out, together with the lens, a sufficient quantity of the vitreous humour to reduce the eyeball to its natural size. In doing this, considerable caution is necessary; for, too much of the vitreous humour is apt to be lost, especially when it is preternaturally liquid, and a permanent and irreducible collapse of the eye may even happen.

The apprehension of such an event introduced the plan of puncturing the eyeball with a very small trocar, at the distance of about two or three lines from the margin of the cornea, and thus discharge as much of the humours as necessary.

The redundant contents of the eye may, indeed, be evacuated by an operation; but there is greater difficulty in preventing a fresh accumulation of fluid, and the disease generally returns. The operation, when done once only, promises some chance of durable benefit, if the surgeon perform it in an early slage of the case. Benjamin Bell met with such success. Nuck also effected a radical cure by repeating the operation a certain number of times. We are not then to relinquish all hope, even though the disorder may recur. But, one thing seems now to be quite established, namely, the impossibility of accomplishing a perfect cure, and restoring the original integrity of the eye, when once this organ has suffered such dilatation, that the function of vision is destroyed.

If the surgeo prefers letting out the redundant quantity of the humours in one of the foregoing ways, an endeavor is afterwards to be made to improve the tone of the eye with corroborant applications. The eye may be bathed with cold water, a decoction of oak bark, or any spirituous aromatic collyrium.

When the disease has attained such a degree, that the fight is entirely lost, and the eyeball dilated far above its natural size, it is best to give up all idea of attempting a radical cure; the humours may be discharged, and an artificial eye afterwards worn.

Scarpa places little reliance in the paracentesis ocu!la as a means of effecting a permanent cure of hydrophthalmia. Indeed, he maintains, that it can never succeed, unless the puncture, made by the trocar, excite inflammation and suppuration of the interior of the eye. The method recommended by this eminent writer, is to remove a circular piece of the centre of the cornea, about three lines in diameter. Thus, an opening is made, which at once serves for the discharge of the humours, and to excite the requisite degree of inflammation within the eye. The incision should be made in the cecotoma.

The sight being irrecoverably lost, Scarpa advises surgeons to introduce a small billiary across the apex of the cornea, at one line and a half from the central point of this membrane, whether affected with opacity or not. The little circular flap is then to be raised with a pair of forceps, and the incision continued into a complete circle by directing the edge of the knife upwards. Through the circular aperture, thus made in the middle of the cornea, the surgeon is gently to press out as much of the superabundant humours of the eye as is requisite to lessen the eyeball, and make it return into the orbit, so as to admit of being covered by the eyelids.

Scarpa recommends merely applying a pledge of dry lint, and a retentive bandage, till inflammation begins, which generally happens about the third or fifth day. Such remedies are now to be employed as appear best calculated to moderate the inflammation; and a breed and milk poultice is to be applied to the eyelids, and changed every two hours. When the commencement of inflammation on the eyeball subsides so considerably, as to project from the orbit again, the prominent part is to be covered with a liniment of oil and wax, or the yolk of an egg mixed with some oelum hyperici. Either of these dressings is to be laid under the breed and milk poultice. In proportion as the internal suppuration of the eye begins, the swollen state of this organ undergoes a gradual diminution.

When the removal of a piece of the cornea, to the extent above specified, fails to excite a mild inflammation and suppuration of the interior of the eye by the fifth day, Scarpa advises us either to expose the eye to the air, or to cut away a little of the whole edge of the opening already made in the cornea, so as to bring on the kind of inflammation and suppuration essential to the cure. Scarpa fulis principal malattie degli occhi, cap. 18.

The late Mr. Ford introduced a sphen through the eyeball, for the purpose of lessening the size of the organ when affected with hydrophthalmia. Medical Communications, vol. 1.

After operating for the relief of the present affliction, a fungus occasionally grows out of the internal part of the eye. Such an excrescence was, in one instance, destroyed by the external employment of belladonna. (Terras, Journal de Medecine, tom. 45.) But in cases this or other means have failed.
HYD

fail in preventing the reproduction of the fungus, the fungus is called upon to recommend the entire extirpation of the eye. See Extirpation of Eye.

Gen. Ch. Cal. Perianth of one leaf, erect, superior, permanent, divided into four, ovate, acute, bordered, somewhat fleshy segments. Cor. of one petal, funnel-shaped; tube longer than the calyx; limb angulated, divided into four ovate, revolute segments; throat bearded. Stam. Filaments four, inserted at the funnuit of the tube, decurrent, erect, longer than the corolla; anthers somewhat fescape-shaped. Fil. Germin oblong, inferior; style thread-shaped, curved; stigma bident. Peric. Berry dry, ovate, compressed, having three ribs on each side, the middle one highest, with an attenuated margin, a little incurved, fleshy, two-celled, with a transverse partition. Seeds solitary, oblong, triangular, rough, having two furrows on the inner side.

1. H. maritima. Linn. Suppl. 126. (Sarillas acepe; Gartn. 118. t. 25. f. 4.)—Found by Kenig on loose sand by the sea, near Gudalur, in the East Indies.—This is the only species known. It has the habit and appearance of Arenaria marina, but is larger.—Root simple, thread-shaped, red, fleshy, sweet. Stem creeping, smooth, coloured, jointed, very long, furnished with obtuse, mucronate, permanent sheaths. Leaves opposite, spreading, ovate, acute, entire, fleshy, shining, interspersed with small, whitish, pelliculc tubercles; leaf-tasks short, sheathing the stem, and becoming, when the leaves fall. permanent sheaths. Flowers axillary, usually in pairs, but not opposite, erect, of a pale blue colour. Anthers blue.

Gen. Ch. Cal. Perianth scarcely shorter than the corolla, spreading, permanent, of five deep,awl-shaped segments. Cor. of one petal, campanulate, cloven into five, erect, obtuse, emarginate segments; nectary, a chink closed by two longitudinal converging plates, fastened to the petal, within the middle of each segment. Stam. Filaments five, awl-shaped, longer than the corolla; anthers incumbent, oblong. Fil. Germin ovate, pointed; style awl-shaped, the length of the stamens; stigma bident, acute, spreading. Peric. Capsule globose, of one cell and two valves. Seed solitary, round, large.

1. H. virginianum. Linn. Sp. Pl. 208. Lamarck. Ilustr. t. 97. f. 1.—"Leaves pinnatifid."—Native of Virginia and Carolina, on a moist boggy soil; flowering in May and June. A hardy herb, whose root is fibrous, and spreading. Leaves rising from the root on footstalks, indented on their edges, very, of a thinning green. Flowers also coming from the root, hanging down in loose clusters, rather inconspicuous. Seeds irregularly ovate and angular, elegantly reticulated with very minute excavations, yellowish white.

2. H. canadensis. Linn. Sp. Pl. 208. Lamarck Ilustr. t. 97. f. 2.—"Leaves lobate-angular."—Native of Canada, and flowering in May.—Very similar to the last except in foliage, and in this respect H. canadensis is not unlike the Acer or Maple, for its leaves are half five-lobed, finely, with the lobes acute, slightly toothed, and having a finus at the infliction of the footstalk.

These plants are very hardy, and should be placed in a moist rich soil.

3. H. appendiculatum. Michaux. Boreal.-Amer. v. 1. 154.—"Very hairy all over. Radical leaves somewhat pinnatifid. Sinuses of the calyx with reflexed appendages."—Michaux found this in mountainous woods of North America. He describes the flowers as in somewhat pinnated clusters, of a blueish colour, their calyx having reflexed appendages, like some species of Campanula.

HYDROPHYSOECELE, an old term in Surgery, implying a hernia, in which a good deal of fluid and air is contained. The word is compounded of θήρ, water, ψεσιον, a fistula, and μεσως, a hernia.

HYDROPE, synonymous with dropsey, being the adjective from hydrops: which see.

HYDROPIDER, in Botany. See ELATINE.

HYDROPEUMATOCOELE, from θήρ, water, ψηφος, ψεσιος, and μεσως, a tumour, a hernial swelling containing a large proportion of air and fluid.

HYDROPEUMOSA RCA, an ancient term in Surgery, signifying a tumour containing water, air, and any fleshy substance. The word is derived from θήρ, water, ψηφος, ψεσιος, and μεσως, a hernia.

HYDROPEUTA, of τερατον, formed of θήρ, water, and τερας, drinker, of νεφις, I drink, in Medicine, a person who drinks nothing but water.

It has long been considered among physicians, whether or no the hydropic lived longer than other persons? See DRINK.

HYDROPS, θήρ, of ψεσιον, aqua, and νεφις, vultus. See DROPSY.

Hydrops ad natum, literally "a dropsey into the chamber-pot," a term sometimes used to signify a diabetes.

HYDROPYRETOS, formed of θήρ, water, and θερις, fever, a word used by some authors to express a malignant fever, attended with very copious sweats. Some make it the same with the fudor Anglicus, or sweating sickness.

HYDORACHITIS, from θήρ, water, and αρης, the spine, denotes, in Surgery, a particular kind of tumour situated on the vertebra, remarkable for being of a molten incurable nature; and proving fatal, when it bursts or is punctured,
HYDORHODINON, formed of \( \theta\nu\mu\eta\rho\), \( \omega\nu\tau\rho\), and \( \rho\xi\tau\alpha\nu\) \( \rho\xi\tau\alpha\nu\); a name given by the ancients to a mixture of water and oil of roses. This, as it was at once cooling and emetic, was very much used by the ancients, to provoke vomiting after the taking of poisons.

HYDROROSATON, in the *Writings of the Ancient Physicians*, a name given to a drink made of water, honey, and the juice of roses. The proportions were four pounds of roses, five pints of water, and two pints of honey.

HYDROSAARCA, from \( \theta\nu\mu\sigma\alpha\), water, and \( \sigma\alpha\zeta\), \( \sigma\alpha\zeta\), in *Surgery*, any sthly tumour containing fluid.

HYDROSAARCOCELE, from \( \theta\nu\mu\sigma\alpha\), water, \( \sigma\alpha\zeta\), \( \sigma\alpha\zeta\), and \( \kappa\omicron\lambda\omicron\), \( \kappa\omicron\lambda\omicron\), signifies a hydrocele, or preterrenal accumulation of fluid in the tunica vaginalis, attended with a chronic enlargement or induration of the testicle. See HYDROCELE and SACROCELE.

HYDROSCOPE, \( \theta\nu\mu\sigma\sigma\omicron\varsigma\), formed of \( \theta\nu\mu\sigma\), water, and \( \sigma\alpha\zeta\), \( \sigma\alpha\zeta\), I consider; an instrument actually used for the measuring of time.

The hydrocope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom; the cylinder was graduated, or marked off with divisions, to which the top of the water became successively contiguous, as it trickled out of the vertex of the cone, pointed out the hour.

Symeis describes the hydrocope at large in one of his letters. See CLEPSYDRA.

HYDROSTATINUM, in *Botany*, a name given by some authors to small scalianum.

HYDROSTATIC BALANCE, a kind of balance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid.

The instrument is of considerable use in estimating the degree of purity of bodies of all kinds; the quality and richness of metals, ores, minerals, &c. the proportions in any mixture, adulteration, or the like; of all which the specific weight is the only adequate test.

The hydrostatical balance is founded on this theorem of Archimedes, that a body heavier than water weighs les in water than in air, by the weight of as much water as is equal to it in bulk. Whence, if we subtract the weight of the body in water from its weight in air, the difference gives the weight of as much water as is equal in magnitude to the solid proposed.

Having, therefore, two bodies, the one firm, the other fluid, together with the weight of each part; to find their proportion, divide the greater by the less; the quotient compared to one, that is, unity, will be the antecedent of the proportion desired.

The instrument, with its apparatus, is represented *Plate X.*, figs. 7 and 8, *Hydraulics*, and needs little description. See Gold.

A B is a nice balance, turning with a small part of a gram, and furnished with a long examined D, for determining the exact horizontal position of the balance.

1. To find the specific gravity of a liquid; hang to the end B of the beam the little scale S, and to the bottom of the scale S, by a horse-hair, which is of the same specific gravity with the glass bubble G, which must be specifically heavier than any fluid except mercury. To the opposite end A of the beam hang a brass scale E, which is a counterpoise to the bubble G, immered in water; but when the bubble hangs out of the water, a weight must be laid on E to keep it in equilibrium, which weight will be equal to what the bubble loit in water, or to a bulk of water equal to the bubble; when rain-water is used, this weight will be a thousand grains. Then fill a cylindrical vessel I, about two-thirds with common water; and when the bubble is let into it, the beam will remain in a horizontal position, if the water be of the same specific gravity as that in which the bubble was adjusted; if it be not, there will be a variation, which is to be corrected by means of little weights for that purpose. Having thus adjusted the bubble in water, the specific gravity of any other fluid will be found by weighing the bubble in it; and since you always weigh so much of the liquid as is equal to the bulk of the bubble, if there be any difference between such quantity and the like quantity of water, it will be discovered by putting weights into the ascending scale. E.g. if red port wine be put into the vessel I, the bubble will sink, and require the addition of ten grains in the scale E, when the balance has been adjusted in rain-water, for restoring the equilibrium; which shows that port wine is lighter than rain-water ten parts in a thousand, or one hundredth part. If proof brandy be used, seventy-seven grains will be required to restore the equilibrium, and therefore brandy, or proof spirits weighs, seventy-seven parts in a thousand, or one hundredth part less than rain-water. But in a denser medium G would rise; and if sea-water be used, twenty-six grains must be put into the scale S to restore the equilibrium, which shows that sea-water is twenty-six parts in one thousand, or one eighteenth part heavier than rain water.

2. To find the specific weight of a solid; instead of the bubble, hang on the glass bucket K, *fig. 8*, which with its suspending piece H, will be in *equilibrio* with the counterpoising scale E. Having weighed the solid in air, by the bucket, by counterpoising it with weights on the scale E, note its weight; but because not only the solid to be tried, but the glass bucket itself will lose of its weight when immersed in water, you must restore to the bucket the weight that it loses by being immersed, that the body in it alone may be examined: this is done by means of the piece F, which weighs just as much as a bulk of water equal to the bucket; and being fllocked on the suspending piece at H, it not only relores to the bucket what it had lost by being immersed in water, but makes a scale for receiving weights, in order to restore the equilibrium to the solid contained in the bucket, and to flew how much it has lost of its weight in water. When many bodies are to be weighed hydrostatically, it is best to weigh them in the air successively, and set down their weights before you begin to weigh them in water, because it would be troublesome to dry the bucket every time. Care must also be taken that no bubbles of air adhere to the bodies weighed in water, which would make them lighter.

Dr. Defaguliers has added a contrivance to this machine to make it more nice, see *fig. 9*. S, S, S, are three frets which serve to set the foot and stem upright; and O M is a string and plummet, whose point hanging over M, shews when the piece PC is truly vertical. There is also a piece E O, which has a slit to compare with the examen D playing in the notches C. Delag. Exp. Phil. vol. ii. P. 196.

Mr. Martin propoges the following confection of an accurate hydrostatical balance. A B, (see *fig. 10*) is the foot on which it stands; C D, a pillar supporting a moveable brass plate E F, fastened to it by the ferew in the knob: In the end of this plate is fixed an upright piece I K, supporting another plate G H, which slides backwards and forwards thereon, and is moveable every way about it. In the end of this plate at H, is fixed (by a nut beneath) a wire L M, taped with a fine thread from one end to the other;
upon the swan-neck flip of brass N O, to which a very exact balance is hung at the point N; to one of whose scales P, is appended the heavy body R, by a fine horse-hair, or piece of silk S; the weight of the said body R in the air is expressed by the weights put into the scale Q to make an equilibrium therewith, which being destroyed by immersing the fluid in the fluid TV, contained in the glass W V, is again restored by weights put into the scale P. So that the weights in the scale Q compared with those in the scale P, shew at once the specific gravity of the fluid R to that of the fluid TV.

For several other constructions of this instrument, designed for greater accuracy than that of the common form, the reader may consult St. Gravemande's Physics Elec. Math. &c. tom. i. lib. 3. cap. 3. The specific gravities of small weights may be determined by suspending them in loops of horse-hair, or silk threads, to hook at the bottom of the scale of the common hydrostatic balance. E. g. if a guinea suspended in air be counterbalanced by 129 grains in the opposite scale; and upon being immersed in water, requires \( \frac{74}{5} \) grains to be put into the scale counter over it, in order to restore the equilibrium; we thus find that a quantity of water of equal bulk with the guinea, weighs \( 7 \frac{1}{2} \) grains, or 7.49; by which divide 129, the weight of the guinea in air, and the quotient, or 17.793, shews that the guinea is so many times heavier than its bulk of water. Whence, if any piece of gold be tried, by weighing it first in air, then in water, and if upon dividing the weight in air by the lbs in water, the quotient is \( 17.793 \), the gold is good; if the quotient be 18, or between 18 and 19, the gold is very fine; but if it be less than 17.4, the gold is too much alloyed with other metal. If the try be carried in this manner, and found to be eleven times heavier than water, it is very fine; if it be \( 10 \frac{1}{2} \) times heavier it is standard; but if it be any less weight, compared with water, it is mixed with some lighter metal, such as tin.

In order to find the specific gravities of those bodies that are lighter than water, let any upright tube be fixed into a thick flat piece of brass, and in this fluid let a small lever, whose arms are equally long, turn upon a fine pin as an axis. Let the thread which hangs from the scale of the balance be tied to one end of the lever, and a thread from the body to be weighed, be tied to the other end. This done, put the body of water into a vessel; then pour the water into the vessel, and the body will rise and float upon it, and draw down the end of the balance from which it hangs; then put as much weight in the opposite scale as will raise that end of the balance, so as to pull the body down into the water by means of the lever; and this weight in the scale will shew how much the body is lighter than its bulk of water. Ferguson's Lect. p. 160. 8vo.

Otherwise: Take another body of a compact form, but much heavier than an equal bulk of water, so that when this body is connected with the body in question, they may both sink in water. This being prepared, ascertain the weight of the lighter body in air, and the weight of the heavier body in water. Then tie, by means of thread, both bodies together, but not so closely as to exclude the water from, or to labour bubbles of air between them; and weigh them both in water. Now since the heavy body is partly buoyed up by the lighter body, the weight of both in water will be less than the weight of the heavier body alone. Subtract the former from the latter, and add the remainder to the weight of the lighter body in air; for this sum is the weight of a quantity of water equal in bulk to the lighter body. Therefore the weight of the lighter body in air must be divided by the last-mentioned sum, and the quotient will express the specific gravity of the lighter body.

E. 5.—A piece of elm being varnished in order to prevent its absorbing any water, was found to weigh in air 920 grains. A piece of lead, which was chosen for this purpose, and the piece of lead were tied together, and being suspended from the hook of the scale, &c. in the usual manner, were found to weigh in water 331.7 grains, viz. 580 grains less than the lead alone; therefore 580 was added to 920 (viz. to the weight of the elm in air) and made up the sum of 1500. Lately 920 was divided by 1500, and the quotient 0.6133 expressed the specific gravity of the piece of elm.

In the use of the hydrostatic balance, it will be proper to observe the following general precautions. The water in which the solid is to be weighed, besides its being either distilled or rain water, must be quite clean. Its temperature, as well as that of the solid, must be as near as possible to 62° of Fahrenheit's thermometer; for which purpose the ball of the thermometer must be placed in the water, and the temperature is adjusted by the addition of hot or cold water. If the solid body be soluble in water, or if it be porous enough to absorb any water, then it must be varnished, or smeared over with some oily or greasy substance, but in that case some allowance must be made on account of the varnish, &c. When the solid is weighed in water, its upper part ought to be a little way below the surface of the water, for in liquids about an inch, and it must by no means be suffered to touch the sides or bottom of the jar. Care must be had that no bubbles of air adhere to the solid under water; for they would partly buoy it up. These may be easily removed by means of a leather. The solid must be of a compact form, and free from accidental or artificial vacuities, so as not to harbour any air; for otherwise its specific gravity cannot be ascertained by weighing in water, &c. Thus a piece of silver, which is much heavier than water, may be formed into a hollow sphere, which will appear to be much lighter than water; for if this sphere were immered in water, it would displace a quantity of water which is equal not only to the silver, but also to the space which is contained in the sphere. It is for this reason that a chip might be made of iron, or of copper, or, in short, of any substance whose specific gravity is less than that of water, and yet it would float well as a chip which is made of wood, in the usual way. See Specific Gravity.

**HYDROSTATIC BELLOWS, in Hydrostatics, is a machine for demonstrating the upward pressure of fluids (see Fluid), consisting of two thick oval boards A, (Plate X. Hydrostatics, &c. fig. 11.) each about sixteen inches broad, and eighteen inches long, covered with leather, to open and shut like a common bellows, but without valves, only a pipe B, about three feet high, is fixed into the bellows at C; let water be poured into the pipe at C, which will run into the bellows, and separate the boards a little. Then lay three weights b, c, d, each weighing a hundred pounds, upon the upper board; and pour more water into the pipe B, which will run into the bellows, and raise up the board with all the weights upon it; and if the pipe be kept full until the weights are raised as high as the leather, which covers the bellows, will allow, the water will remain in the pipe, and support all the weights upon it; even though it should weigh no more than a quarter of a pound, and these three hundred pounds; nor will all their force be able to cause them to descend and force the water out of the top of the pipe. The reason of this will appear, if we consider that if a hole be made in the upper board, and a tube be put into it, the water will rise in the tube to the same height as it rises in the pipe; and would rise as high by supplying the pipe in as many tubes as the board could contain holes. Now,
Now, suppose only one hole to be made in any part of the board, of an equal diameter with the bore of the pipe B, and that the pipe holds just a quarter of a pound of water; if a person puts his finger upon the hole, and the pipe be filled with water, he will find his finger to be pressed upward with a force equal to that of a quarter of a pound. As the same pressure is equal upon all equal parts of the board, each part, whose area is equal to the area of the hole, will be pushed upward, with a force equal to that of a quarter of a pound; the sum of all which pressures against the under side of an oval board, sixteen inches broad, and eighteen inches long, will amount to three hundred pounds: and therefore, so much weight will be raised up and supported by a quarter of a pound of water in the pipe. Hence, if a man stands upon the upper board, and blows into the bellows through the pipe B, he will raise himself upon the board; and the smaller the pipe of the pipe is, the easier he will be able to raise himself; and then by putting his finger upon the top of the pipe, he can support himself as long as he pleases; provided that the bellows be air-tight.

Mr. Fergufon has described another machine, which may be substituted instead of this common hydrostatical bellows: A B C D, fig. 12, is an oblong square box, in one end of which is a round groove, as at a, from top to bottom, for receiving the upright glass tube I, which is bent to a right angle at the lower end as at i, in fig. 13; and to that part is tied the end of a large bladder K, which lies in the bottom of the box. Over this bladder is laid the movable board L, figs. 12, and 14, in which is fixed an upright wire M; and leaden weights N N, to the amount of sixteen pounds, with holes in their middle, are put upon the wire over the board, and press upon it with all their force. The crofs bar p is then put on to secure the tube from falling, and keep it in an upright position; and then the piece E F G is to be put on, the part G sliding tight into the dovetailed groove H, to keep the weights N N, horizontal, and the wire M upright, which is received into a round hole r, in the part E F. There are four upright pins in the four corners of the box within, each almost an inch long, for the board L to rest upon, in order to keep it from prefling the fides of the bladder below it close together at first. The whole being thus put together, pour water into the tube at top, and the water will run down the tube into the bladder below the board, and after the bladder has been filled up to the board, continue pouring water into the tube, and the upward pressure of the bladder will raise the board with all the weight upon it, even though the bore of the tube should he so small, that lefs than an ounce of water would fill it. Fergufon's Lectures, Supplement, 1767. p. 16.

Hydrostatic Instrument, Bradford's, is an invention for weighing money and discovering its defect either of weight or purity. It consists of a thin flat brass ruler, about half a foot long; on each side of which are two graduated lines, those on the upper side marked X and X (see the Plan X, Hydraulics, p. 15, N 1.) and those on the other side B and W, ibid. N 2. There are also a small chain and pincers wherein to fix the piece of money intended to be weighed and proved, together with two pair of centre pins, marked A and B, ibid. N 2 and 3. being the points of suspension of the rod when used; whereof the former pair A are to be used for proving all pieces of gold under thirty-fix shillings value; and the other pair, marked B, for all pieces from thirty-fix shillings to twenty-two shillings, or three pounds twelve shillings. Lately, there is a sliding piece, or index C, ibid. N 3, by the motion of which, backward or forward, until the point of equilibrium is discovered, the value of any piece suspended in the pincers is found upon the graduated lines already mentioned. Of these lines, those marked A and B are called ftagal lines, as being calculated for weighing the piece in air, and those marked W W, are called hydrostatical lines, as serving to point out the alloy or adulteration of the piece weighed. A whole division on each line is equal to the weight or value of one shilling in gold; a half division to fix-pence, and a quarter division to three-pence.

To prove a guinea: first suspend it in the pincers, and then placing the inside of the sliding-piece C to twenty-one on the line A on the upper side of the ruler, which must move freely on the centre pin marked A, and if the guinea and sliding-piece exactly balance each other, the guinea is full weight; if not, move the pincers backwards or forwards until they equiponderate; when the division cut by theinside of the slider is the true weight of the gold; and if it refts for imitation, at twenty and a half, then the guinea weighs only twenty shillings and fixpence. In the next place, to prove the alloy of this piece, let the slider be brought to the division twenty and a half, upon the hydrostatic line marked W, for whatever division is cut by the slider in weighing on the flat lines, it must be placed at the same on the hydrostatic line adjoining. Then let the piece, together with the pincers, and the brass link wherein it is suspended, be immersed in water (ibid. N 3.) as far as the note reaches on the said link; if then the instrument acts in equilibrium, or the piece sinks deeper in the water, the guinea is standard gold; but if the slider must be moved farther backward before it will equiponderate, the guinea is adulterated.

If it is alloyed with silver, allow two shillings for every penny it wants in the hydrostatic weight; and then if the number of pence the piece is deficient in weight hydrostatically when doubled, exceed the number of shillings it weighs flatly, it may be concluded to be adulterated with some bafertal than silver. However, a more speedy method of discovering whether a piece of gold be adulterated or not, without moving the slider more than once, is this: when the piece is weighed flatly, bring the slider to the division on the hydrostatical line expressing its weight; and immuring the pincers and pincers as before, so that the surface of the water may be exactly on the mark on the long line, if the instrument does not then balance, gently lower the band that holds the fluid, until the instrument comes to an equilibrium; at which time, if the guinea be a counterfeit, great part of the pincers will appear above the water; if a 36. piece be tried, not only the pincers, but a small part of the coin, will appear above the surface, if the piece be counterfeit. This last method is sufficiently near the truth for common practice.

If there is occasion to weigh and prove a very small piece of gold, as a 2s. 3d. 4s. 6d., &c. the method is, to put the said pieces in the pincers, with some other piece that has been approved before; by which means the weight and alloy of the small piece may be easily discovered, as above. If the piece be above 36s. the slider is to be placed according to the divisions of the ftagal and hydrostatical lines on the under side of the instrument, which are fitted to the standard of the mint, by which a guinea weighs 120 grains. Hydrostatical Paradox, is a principle, which has been already flated, and in some degree illustrated and evinced under the article Fluid, and also under the article of Hydrostatic Balances. It is to be denominated, because at first view it seems to be paradoxical; but it results from the nature of fluids, which prefers every way alike. The paradox is this, that any quantity of water, or any other fluid, how small soever, may be made to balance and support any quan-
HYD

...ity, or any weight, how great forever. Thus, water in a pipe or canal, open at both ends, always rises to the same height at both ends, whether those ends be wide or narrow, equal or unequal. And since the pressure of fluids is directly as their perpendicular heights, without any regard to their quantities, it follows that whatever the figure or size of the vessels may be, provided their heights be equal, and the areas of their bottoms equal, the pressures of equal heights of water are equal upon the bottoms of those vessels; even though the one should contain a thousand or ten thousand times as much as the other. Mr. Ferguson has illustrated and confirmed this paradox by the following apparatus. Let two vessels, (Plate XI. Hydraulics, fig. 16.) such as A B and C D, be of equal heights, but very unequal capacity; let each vessel be open at both ends, and their bottoms E and F of equal widths. Let the brass bottoms G and H be exactly fitted to each vessel, not so as to go into them, but for each vessel to rest upon respectively; and let a piece of wet paper be put between each vessel and its brass bottom, for the sake of keeping them close. Join both end of its vessel by a hinge D, so that it may open like the lid of a box; and let each bottom be kept open by one vessel by equal weights W, hung to lines which pass over the pulley E, whose blocks are fixed to the sides of the vessels at F, and the lines tied to hooks at d, fixed in the brass bottoms opposite to the hinges D. Things being thus prepared, hold one vessel upright in the hands over a basin on a table, and cause water to be poured slowly into it, till the pressure of the water bears down its bottom at the side d, and raises the weight E; and then part of the water will run out at d. Mark the height at which the surface H of the water flood in the vessel, when the bottom began to give way at d; and then, holding up the other vessel in the same manner, cause water to be poured into it; and it will be seen that when the water rises in this vessel just as high as it did in the former, its bottom will also give way at d, and it will lose part of the water.

The natural reason of this surprising phenomenon is, that since all parts of a fluid at equal depths below the surface, are equally pressed in all directions, the water immediately below the fixed part B F will be pressed as much upward against its lower surface within the vessel, by the action of the column A G, as it would be by a column of the same height, and of any diameter whatever; and therefore since action and reaction are equal, and contrary to each other, the water immediately below the surface B F will be pressed as much downwards by it as if it were immediately touched, and pressed by a column of the height A G, and the diameter B F; and therefore the water in the cavity B D d f will be pressed as much downward upon its bottom G, as the bottom of the other vessel is pressed by all the water above it. Ferguson's Lectures, p. 105.

HYDROSTATICS, composed of hydro, water, and stasis, settle, of static, settle, standing, of stand, stand, hydrostatics being conceived as the doctrine of the equilibrium of liquids, is the doctrine of gravitation in fluids; or that part of mechanics which considers the weight or gravity of fluid bodies, particularly of water, and of solid bodies immersed in them.

To hydrostatics belongs whatever relates to the gravities and equilibria of liquids, with the art of weighing bodies in water, in order to eliminate their specific gravities.

Mr. Boyle has applied hydrostatics to good purpose, in examining and proving the good news and purity of metals, minerals, and other bodies, particularly fluids, in an express treatise, entitled "Medicina Hydrostatica."

The laws of hydrostatics, with the application of them, fee delivered at large under the articles Fluid and Specific Gravity.

Hydrostatics are frequently confounded with hydraulics, on account of the affinity of the subjects; and several authors chase to treat of the two promiscuously. See hydraulics.

The oldest writer on hydrostatics is Archimedes, who first delivered the laws of them in his book "De indidentibus humido." Marin Ghetaldus first brought his doctrine to experiment, in his "Archimedes Promotus." and from him Mr. Oughtred took the greatest part of what he has given us on this subject. The celebrated M. Pascal has written an excellent treatise on this subject, entitled "Traite de l'Equilibre des Liqueurs et de la Penteante de l'Aire." M. Mariotte, in a French treatise, published at Paris in 1686, "Of the Motion of Water and other Fluids," gives most of the propositions of hydrostatics and hydraulics, proved by reason, and confirmed by experiments. The Jesuit F. Terris de Lantis, in the third tome of his "Magisterium Naturae Artis," lays down the doctrines of hydrostatics more amply than they are elsewhere found. F. Lamy, in the second part of his mechanics, entitled "Traite de l'Equilibre des Liqueurs," delivers the fundamental laws of hydrostatics and hydraulics; and the like is done by Dr. Wallis, in his "Mechanica." Lastly, Sir Isaac Newton gives some of the sublimer matters in the second book of his Philosoph. Nat. Principle. Mathematic. For an account of other writers on this science, see hydraulics.

HYDRO-SULPHURET, in chemistry, a compound of sulphuretted hydrogen with alkaline and earthy bases, and likewise with metallic oxides. The properties of the hydro-sulphures are: that they are abundantly soluble in water, and are crystallizable; the solution is colourless as long as the action of the air is excluded; but when it is admitted, a yellow colour is soon acquired, owing to the oxygen of the atmosphere combining with the hydrogen of a portion of the sulphuretted hydrogen, while the sulphur combines with the remaining portion of it, forming a super-sulphuretted hydrogen in union with the base. The principal hydro-sulphures are as follow: viz. 1. Hydro sulphuret of potash: this salt is white, and perfectly transparent, resembling the sulphate of soda by its transparency and the size of its crystals. Its taste is at first alkaline, and afterwards extremely bitter; when dry it is without smell, but when liquid it exudes a pungent odour. It attracts humidity from the atmosphere, and pales into a liquid syrup. When fluid, it gives a green colour to bodies in contact with it; it is soluble in water and alcohol, abstracting heat during the solution: with acids, it gives rise to a brine effervescence, without depositing any sulphur. It precipitates the metallic solutions: the precipitates from different metals being of different colours and shades. 3. The properties of the hydro-sulphuret of soda are very like those just enumerated of the potash; but the nitrous and oxy-nitric acids produce a precipitate of sulphur, owing to their decomposing the sulphuretted hydrogen, by affording oxygen to its hydrogen, while the other acids merely expel it. To distinguish the hydro-sulphuret of potash from that of soda: add a few drops of the solution of each to a solution of alumina in sulphuric acid; the potash gives rise immediately to a crystallization of alum; while that of soda has no such effect. 3. Hydro-sulphuret of ammonia is thus produced: when equal parts of sulphuretted hydrogen and ammonia, in their elastic states, are mixed together, they immediately combine; a white cloud is produced, which is condensed, and a thin, soft deposit is formed on the sides of the vessel, which
HYDROTHORACUS. See Diopry.

HYDROTHOTS, formed of "thorax, water, in Medicine. See Hydrotus.

HYDRUNTUM, Ofrante, in Ancient Geography, the most fertile part of Italy, having a port from which it was usual to pass over to Greece; the gulf in that place being fiercely 1 leagues broad. Near it was a cap, called "Hydra Mons."

HYDRUS, or Water Serpent, in Aesop, is a southern constellation, including ten stars. See Constellation.

Hydrus, in zoology, a genus of serpents lately established by Dr. Schneider, and which is designed to contain a number of those species of the serpent tribe that are of the aquatic kind, whether those which reside in fresh waters, or the marine elements; or such as indiscriminately inhabit either.

Most of the snake tribe possess the power of moving in the water with facility, and, from their peculiar conformation, perform the act of swimming with much facility; but the structure of the hydridus is in an eminent manner adapted to this particular purpose, the tail being broad, flat, and compressed, like that of some kinds of fishes, and by means of which it is enabled to direct its course with equal certainty, and swim with equal ease and swiftness. Water serpents are mentioned by various writers of antiquity, as Arilotle, Ælian, and Pliny, and also by others of the middle ages, as well as those of modern times. Ælian speaks of snakes of large size, with flat tails, produced in the Indian sea, and Arilotle mentions others resembling the conger. It is, therefore, very probable that some few of the genus may have been known to them, though it is not less likely they might have confounded the murana with their sea serpents, or perhaps even some of the terrerial kinds of serpents, as the uninformed among the moderns too frequently denominate all those snakes "water snakes" which happen to disconver in the water; without reflecting that those snakes may have only sought shelter in the water in the moment of pursuit, or been discovered in the very instant of time when they have plunged into that element in search of prey.

Bole, and after him other writers of credit on the tribe amphibia, reject the name of hydryus, given by Schneider; that term having been previously applied to a tribe of vernes, the polye or hydra of Linnaeus. They, therefore, since it appears desirable the genus should be retained, adopt it by the name of Hydrepis instead of Hydryus, and under this appellation it is received by the bolt writers at this time. Daudin, it is true, eithens the distinction too diffiuce, and with the exception of a few species continued under the name of enhydrus, returns the hydryus genus of Schneider to the Linnean coluber, but his example is not followed by his own countrymen, among whom the three genera, as before mentioned, seem very generally admitted at this period.

It should be distinctly understood that Mr. Schneider does not include the whole of the water serpents under one genus; he considers their residence in the water as the characteristic only of a tribe, which he subdivides into two genera, the first of which he calls Hydryus, the other Enhydris. In both the form of the tail is alike, flat, broad, and formed for swimming, but in the shape of the scales and some other particulars they differ materially, those of the hydryus corresponding with the viper (coluber), and the enhydrus with the snake (anguis). A third genus is constituted by still later naturalists of the Hydryus cloubrum of that author, under the name of Platurus, this species being furnished by nature with venemous fangs like the poisonous kinds of snakes. The genus last adverted to was supposed to consist only of a single species, but we find among the Indian serpents described by Dr. Ruffel, some other poisonous kinds, which perhaps belong to this particular genus.

Species.

* Genus Hydria, Schneider. Hydripis.

The form of this species is long and slender; the head small, not broader than the neck, and covered with large scales; the neck cylindrical; the back carinated; sides declining, and belly roundish. The scales on the trunk, tail, and belly are orbicular, close and not imbricated; those on the under part of the body amount to two hundred, and are placed in two rows; those beneath the tail fifty; the teeth small. Schneider supposes this may be the poisonous kind, as he observed a large curved fang-like tooth on each side, concealed as it were in a kind of sheath. The specimen described by Dr. Ruffel was found on the sea beach at Vizzagapatam, and appeared very alert in its motions, yet when put into a vessel of sea-water to be preserved alive, in order to ascertain the effects of its bite, it very soon died. The length of this was about two feet; according to Schneider it grows to a much larger size.

A native of the Indian seas, and said by Forster to be very common near the coast of the island of Otaheite, where it is called the natives Eisiona-tore, and constitutes an article of food; it is about two feet six inches long, and feeds on fish and molluscsous animals, which, according to Forster, it seizes with the utmost avidity. The same species is found in various parts of the Pacific ocean.

Caruleus. Blue, with numerous yellow bands. Shostr, Ruffel.

Length three feet and a half; abdominal scales three hundred and thirty-two; caudal forty. Native of India.

Major. Livid, with brown diarent bands, and hexagonal abruptly carinated scales. Shaw.

Deforbed from a specimen in the British Museum. Its length is more than three feet; its colour pale or livid, marked throughout the whole length of the back by a series of large transverse, semi-current dusky bands; the tail banded more deeply. The length of the tail is about four inches, and the scales which cover it are of a somewhat square or lozenge form, and so disposed as to resemble in some degree the side of a fish; they are all marked by an abrupt middle carina; the dorsal, the body are chiefly hexagonal, and are carinated in the same manner. It appears to be of the poisonous kind, as one of the teeth on each side in the upper jaw is longer than the rest, and on being examined with a lens is evidently tubular, the flot towards the end being much longer in proportion than in that of the rattle-snake. The species is a native of the Indian seas.

Graceis. Anterior part of the body slender, and covered with smooth ovate scales; the posterior end thicker, and covered with smooth abruptly carinated hexagonal scales. Shaw.

Length two feet; head very small, and not of greater diameter than the neck; the tail about an inch and three-quarters in length, colour uncertain, but appears to have been banded all along the upper parts, from the head to the tail,
HYDRAS.

tail, with numerous, equidistant, brown, and somewhat obtusely pointed bands reaching almost to the abdomen, those on the small or cylindrical part of the body being continued into annuli.

**C. ELEGANS.** Blue with dusky blue decurrent bands, and white abdomen. Shaw.

A native of the East Indies; the length two feet; in appearance resembles *Hydrous* major, but the abdomen has a single and perfectly undivided row of hexagonal scales, from the throat to the beginning of the tail; of about the length of an inch in diameter, and forming a carina on that part; back marked by a carina also; tail two inches and a quarter long, and moderately broad. Colour above pale livid blue, beneath white, and marked throughout its whole length by decurrent bands of deeper blue.

**C. CURTUS.** Short, yellowish, with dusky decurrent sub-accumulated bands, somewhat confluent above. Shaw.

A native of the East Indies; the length one foot, the body compressed, and considerably thicker in proportion to its length than the species *c. elegans*; the head flattish; neck and anterior part but little thinner than the rest of the body; tail about an inch long, and of the usual form; back and abdomen carinated, the carina of the latter more obtuse. The general colour is pale yellow, with a pretty close series of deeply decurrent dusky bands from head to tail, and which are so disposed as to appear alternately confluent on the upper part of the back, more especially near the head. Described from a specimen in the British Museum.

**S. LANCETIFERUS.** Yellowish, with brown bands longitudinally confluent beneath; the body spirally contorted. Shaw.

An elegant species, of a slender form, and about two feet in length, the body much compressed throughout; the dorsal carina very acute, that of the abdomen with a flattened edge of scales somewhat wider than the rest, and about the fifteenth of an inch in diameter; the head small, mouth wide; scales on the head large, those on the body moderately small, ovate, and slightly carinated. The general colour is yellow, with bars of deep chestnut brown, each divided on the abdomen; and the back from about the middle nearly to the tail is marked with a series of large round, blackish spots. "The most remarkable circumstance in this snake (says Dr. Shaw) is the singular obliquity of its form; the body in different parts being alternately flatter on one side than the other, and the pattern completely expressed on the flattened side only; the other, or more convex side, being unmarked by round spots, and lying as it were beneath; thus constituting several alternate spiral curves." Gen. Zool.

**Genus Enhydris.**

**CASPUS.** Cinereous olive with four rows of obicular black spots disposed in quincunx order down the back; abdomen yellow, tesselated with black. *Caluber hydrus*, Pallas.

Inhabitats the Caspian sea and also the Rhine, the length about three feet; tail almost black, and terminated by a small double point, one beneath the other. The head is small, the eyes surrounded by a yellow circle; teeth numerous, small, and placed in two rows; the tongue very long and black.

Described by Dr. Ruffel as being about twenty inches in length, the colour dark blue and changeable; the yellow of the abdomen inclining to white; head small and covered with large scales; anterior part of the body slender, the circumference of the trunk, in the thickest part, about two inches and a quarter; and the tail short, small, taper and compressed. The specimen mentioned by Dr. Ruffel was taken in an Indian lake called Aukapally in one of the traps placed there for catching eels. It is supposed to be harmless, having no visible fangs.

Inhabits India; the length three feet and a half, the thickening near the head three inches; in the middle of the body four inches and a half; the snout projecting, broader than the neck, and forming a kind of beak which is discovered with small lambre, the remainder of the head, with the whole of the upper part, becket with ovate or sub-ovicular carinated scales; eyes small and vertical; mouth moderate; teeth close set, small, irregular, and not reflex. Colour of the fealy part of the front pale cinereous. Tail rather compressed, eight inches in length, somewhat tapering, and obtuse at the end.

**PISCATORUS.** Yellowish brown, with numerous round black spots united by black lines, and disposed in oblique rows. *Hydrous piscator*, Schneider. *Nehi Kans*, Ruffel.

Length two feet nine inches; circumference three inches and a half; head rather broad, ovate, and somewhat decussated, with the sides compressed; tail eleven inches in length, slightly carinated, tapering very gradually, and terminating acutely; the abdomen yellowish white. The species is a native of India, and is esteemed a water snake, as it frequents the wet paddy fields; it moves swiftly, and carries its head high, with a menacing air, but is not a poisonous species, and cannot easily be irritated. When provoked it would neither hiss nor snap at a stick presented to it; nor was it provoked to bite a chicken though pecked several times by the animal. It is known to feed on fish.

**PALUSTRIS.** Brownish yellow, with rhomboid brown spots edged with black; abdomen pearl colour; tail above reddish white. *Hydrous palustris*, Schneider. *Porogodon*, Ruffel.

Resembles the last; the length more than two feet; trunk round; head broadish, oblong, and covered with large scales; tail round, about five inches and a half long and very taper; between each of the oblique rows of brown rhomboidal spots is a ferruginous line, the whole having a decussated appearance; the tail plain and immaculate. According to Dr. Ruffel, this species is not uncommon in India, frequenting the damp grounds, and the borders of tanks, and growing to a size much superior to the former.

**DORSALIS.** Dirty white, with a dorsal black band finned at the edges. *L'Enhydris dorsalis*, Boie.

The length about one foot; head ovoid; abdomen carinated. Country unknown.

**Genus Platurus.** Armed with venomous Fangs.

Native of the Indian and American seas; its general length two feet six inches, or more; the head is covered with large scales; the body cylindrical; tail flattened and somewhat dilated at the tip. This is a poisonous serpent, but the fangs are remarkably small in proportion to the size of the creature.

**LANCEOLATUS.** Back blue, under the belly yellowish; tail lanceolate and entirely blue.

A native of the Indian seas, and is called by the inhabitants
..ants in the English settlements Hoglin; it is two feet and a half in length; the series of abdominal scales three hundred and six, and those of the tail forty-eight. This and the following species are extremely dangerous, their bite proving mortal in a few minutes.

ALEU. White with numerous blue bands; tail obtuse.

Described by Dr. Ruffel as a native of India, under the name of Chittul. The length is three feet, the number of abdominal scales is three hundred and eight; and those of the tail forty-eight.

HYELA, in Ancient Geography, a river of Asia, in Bithynia, called by Pliny Hylas.—Alfo, a town of Arabia Felix, in Ptol.

HYELLA, a maritime town of Magna Graecia, in Lucania, called also Hylæa Strabo.

HYELLUM, a town of Asia, in Phrygia, upon the Meander.

HYEMAL SOLSTICE, the fame with winter solstice. See SOLSTICE.

HYEMANTES, in the Primitive Church, offencers who had been guilty of such enormities, that they were not allowed to enter the porch of the churches with the other penitents, but were obliged to stand without, exposed to all the inclemency of the weather.

HYES, in Mythology, a surname given to Bacchus, from the name Hyge, given to his mother Semide: or, according to others, because her face commonly happened in a rainy season; from ἕ, to rain. The Athenians worshipped Jupiter under the character Phivialis, and erected an altar to him on mount Hymetta.

HYETUSSA, in Ancient Geography, a small island situated on the coast of Ionia, over against the mouth of the Meander, and south of the promontory of Trogilium.

HYGEIA, or Hygieia, in Mythology, an epithet given to Minerva, as the goddess of health. Hygieia was represented as one of the four daughters of Eilephus. She often accompanied her father in the mountains of him now remaining, and appears like a young woman, commonly holding a serpent in one hand, and a patera in the other; sometimes the serpent drinks out of the patera; sometimes he twines about the whole body of the goddess.

HYGEINE, Γυγεία, formed of ἱγιάζω, sound, healthy, that branch of medicine which considers health, and discovers proper means and remedies, with their use in the preservation of that state.

The objects of this branch of medicine are, the non-naturals. See AIR, DIET, EXERCISE, &c.

Hygieine, more largely taken, is divided into three parts; prophylactics, which foresees and prevents diseases; sanitaries, employed in preserving health; and analeptics, whose office is to cure diseases, and restore health.

HYGINUS, pope, in Biography, is thought to have been a native of Athens, flourished in the second century, and was brought up as a philosopher by profession. He was elected to the office of bishop of Rome upon the martyrdom of Telesphorus about the year 140, and filled it till his death, which took place three years after. He was the zealous opponent of the doctrines propagated at that period by Valentine and Cerdo, but could not prevent them from making considerable progress. He testified and confirmed the several orders and degrees of the clergy; ordained the solemn consecration of churches, and did many other acts which were regarded, at that period, as of great importance to the interests of the prevailing religion. Moreri.

HYGINUS, CAESAR JULIUS, one of the ancient grammarians, is mentioned by Suetonius as a native of Spain, though some have supposed him an Alexandrian, and to have been brought to Rome after the capture of that city by Julius Caesar. He was appointed keeper of the Palatine library, and received pupils for instruction. He was intimately acquainted with Ovid and other literary characters of the age: he was said to be the imitator of Corinthian Alexander, a Greek grammarian; wrote the lives of illustrious men, which are referred to by Anius Gellius; a volume of examples, and a copious treatise on the cities of Italy. Other works have been attributed to him: but the only pieces that have come down to us, are entitled "Polline Astronomicon, de Munditi et Spheere, ce utrinsque Partium, Declarationes, lib. iv." and a book of fables. The best edition of these works in conjunction is contained in Munkers "Mythographi Latini," Gen. Biog.

HYGRA, of ὑγραῖος, a name given by the ancients to what they called liquid platers, in opposition to those called xeris, or dry ones. These first were a sort of liniments.

HYGROCIRROCELE, composed of ὑγραῖος, moifτ, and σημερός, γύρις χαρταίος, in Medicine, a branch of a vein swelled with ill blood, or other humours: or a varilce tumour of some of the veins of the testes, attended with a gathering of water in the scrotum.

HYGROMETER, or hygrograph, composed of ὑγραῖος, moifτ, and γραφεῖν, in Instrument, a machine, or instrument, whereby to measure the degrees of dryness, or moisture, of the air. It is also called Hygrograph. See the next article.

HYGROMETRY is the term used by Lambert, Saffure, and other writers to denote the science concerning the nature and quantity of aqueous vapour in the atmosphere, and its relation to certain instruments called hygrometers. This branch of meteorology has been greatly improved of late years, and is justly considered of importance, as being intimately connected with physiology, or the science of aqueous meteors in general.

The two great objects of hygrometry are, 1st, To find what quantity of water exists in solution, or in an elastic state, in a given volume of the atmosphere, or, which is still better, in a given perpendicular column reaching to its summit; and, 2dly, To ascertain the disposition of the atmosphere on any occasion to deposit water or to absorb it, or, in more familiar language, its disposition to rain or to be fair.

The earlier philosophers had the second object chiefly in view, on account of the more immediate benefit which seemed likely to be derived from the knowledge of it; but latterly both objects have engaged the attention of those who have pursed this branch of physical investigation. Various means have been applied and instruments used under the name of hygrometers or hygroscopes, to indicate the fluctuations of moisture existing in the atmosphere.

The detail of experimental enquiry may be conveniently digested under five heads; namely, 1. The alternate expansion and contraction of animal and vegetable substances, by dryness and moisture. 2. The quantity of water absorbed from the air by chemical agents having an affinity for it. 3. The quantity of water evaporated under given circumstances. 4. The cold produced by the evaporation of water; and, 5. The dew-point; or that point of temperature at or below which dew is deposited from the atmosphere upon glases or any other smooth substance.

1. On the Expansion and Contraction of Animal and Vegetable Substances by Dryness and Moisture.—It has been long known that animal and vegetable substances of different kinds are subject to contraction and dilatation by moisture and dryness. Mr. Boyle made experiments on ropes, by suspending weights of 30 or 100 lb. to them, which he found were raised 3 M and
and lowered alternately by the moisture and dryness of the air. Amongst the hygrometrical substances of this kind, that have been more or less noticed, may be reckoned ropes and cords of various materials, such as whip-cord, catgut, &c., wood, particularly deal, ivory, whalebone, hair, board of a wild cat, and several other vegetable productions. &c. If these bodies retained the property of being affected by moisture undiminished, they would form comparable instruments for hygrometers or rather hygroscopes; but unfortunately they all in time become lefs tenible than at first.

We shall here give in brief detail an account of the manner in which hygrometers, consisting of the above-mentioned materials, have been constructed.

Stretch a hempen cord or a fiddle-string, as A B (Plate XII. Hydraulics, fig. 1.) along a wall, bringing it over a truckle or pulley B, and to the other extreme D tie a weight E, into which fit a flyle, or index, F G. On the fame wall fit a plate of metal H I, divided into any number of equal parts, and the hygrometer is complete.

For it is a matter of undoubtedly observation, that moistures feelingly shortens the length of cords and stringes; and that as the moisture evaporates they return to their former length; and the like may be laid of a fiddle-string. The weight, therefore, in the present cafe, upon an increafe of the moisture of the air, will affend; and upon a diminution of the fame, it will defend.

Hence, as the index F G will fwe the fpace of afcent and defcent, and thofe fpaces are equal to the increments and decreafes of the length of the cord or gut A B D, the instrument will defcribe whether the air be more or lefs humid now than it was at another given time.

Or thus: if a more fensible and accurate hygrometer be required, drain a whip-cord, or fiddle-string, over feveral truckles, or pulleys, A, D, E, F, and G (fig. 2.), and proceed with the reft as in the former example. Nor does it matter whether the feveral parts of the cord A B, C D, D E, E F, F G, be parallel to the horizon, as expréffed in the prefent figure, or perpendicular to the fame. The advantage of this, above the former hygrometer, is, that we have a greater length of cord in the fame compafs; and the longer the cord, the greater its contraction and dilafion.

Or thus: fallen a twifled hempen cord, or fiddle-string, H W, by one end, falling a weight W (fig. 3.) to an iron hook; and let the other end defcend upon the middle of an horizontal board, or table, A B, and fit an index I. Let it, from the centre B defcribe a circle; which divide into any number of equal parts.

Now, it is matter of obfervation, that a cord or gut twifls itfelf as it is moiftened, and untwifls again as it dries. Mr. Molyneux, fecretary of the Dublin society, writes, that he could perceive this alternate twifling and untwifling in a cord, by only breathing on it eight or ten times, and then applying a cande towards it. Hence, upon an increafe or decreafe of the humidity of the air, the index will fhew the quantity of twifling or untwifling; and, confequently, the increafe or decreafe of humidity, or dryness.

Or thus, fallen one end of a cord or fiddle-string, H I, (fig. 4.) to a hook H, and to the other end fallen a ball K, of a pound weight. Draw two concentric circles on the ball, and divide them into any number of equal parts; fit a flyle, or index, N O, into a proper support, N, fo as the extremity O may almoft touch the divifions of the ball.

Here the cord or gut twifling or untwifling, as in the former cafe, will indicate the change of moisture, &c. by the fucceflive application of feveral divifions of the circles to the index.

Or thus: provide two wooden frames, A B and C D (fig. 5.) with grooves in them; and between these grooves fit two thin leaves of aia, A E F C and G B D H, fo that they may easily slide either way. At the extremes of the frames A, B, C, D, confine the leaves with nails, leaving between them the space E G H F, about an inch wide. On I fall a flip of brafs dented, I K; and in I, a little dented wheel, upon whose edge, on the other fide of the machine, an index is to be put. Laftly, from the centre of the axis, on the fame fide, draw a circle, and divide it into any number of equal parts.

Now, it being found by experience, that ailen wood readily imbibes the moisture of the air, and swells with it; and that moisture flacks, shrinks again; upon any increafe of the moisture of the air, the two leaves A F and B H, growing turgid, will approach nearer each other; and, again, as the moisture abates they will fhrink, and again recede. Hence, as the diftance of the leaves can neither be increased nor diminished without turning the wheel L, the index will point out the changes in refpect of humidity and dryness.

It is to be noted, that all the hygrometers above defcribed become feffibly lefs and lefs accurate; and, at length, undergo no fensible alteration at all from the humidity of the air. The following is much more lafiting; though no hygrometer will ferre for years, like a barometer and thermometer; but whatever be the fubfance of which it is made, will be altered as to become in a great degree useless.

Take the manifold described in the laft article, and in- fift three or four days in the exhausted ball E, (fig. 6.) fublime a sponge, or other body which eafily imbibes moisture. To prepare the fponge, it may be neceffary to wash it firft in water; and when dry again, in water or vinegar, wherein falt ammoniac, or falt of tartar, has been difolved, and let it dry again.

Now, if the air become moist, the fponge, growing heavier, will preponderate; if dry the fponge will be hoifted up, and, consequently, the index will fhew the increafe or decreafe of humidity of the air.

In the laft mentioned hygrometer, Mr. Gould, in the Philosophical Transactions, instead of a fponge, recom- mends oil of vitriol, which is found to grow feffibly lighter or heavier, in proportion to the leffer or greater quantity of moisture it imbibes from the air; fo that being fattiated in the moifell weather, it afterwards retains or lofes its acquired weight, as the air proves more or lefs moist. The alteration in this liquor is fo great, that in the space of fifty-seven days it has been known to change its weight from three drachms to nine; and has shifted an index or tongue of a balance thirty degrees. A single grain, after its full increafe, has varied its equilibrium fo feffibly, that the tongue of a balance, only an inch and a half long, has defcribed an arch one-third of an inch in compafs; which arch would have been abfolute three inches, if the tongue had been one foot, even with fo small a quantity of liquor; confequently, if more liquor, expanded under a large furface, were used, a pair of scales might afford as nice an hygrometer as any kind yet invented. The fame author fuggeds, that oil of fulphur per compamm, or oil of tartar per dilquium, or the liquor of fixed nitre, might be fublimated in lieu of the oil of vitriol.

This balance may be contrived two ways; by either having the pin in the middle of the beam, with a faminer tongue, a foot and a half long, pointing to the divifions on an arched plate, as represented in fig. 6.

Or, the fcale with the liquor may be hung to the point of the beam near the pin, and the other extreme be made fo longs.
long, as to describe a large arch on a board placed for the purpose, as represented in fig. 7.

Mr. Arderon has made some amendment in the sponge hygrometer. He directs the sponge A (fig. 8.) to be so cut as to contain as large a superficial as possible, and to hang by a fine thread of silk, upon the beam of a balance, and exactly balanced on the other side by another thread of silk at D, swung with the smallest lead-shot, at equal distances, so adjusted as to cause an index E, to point at G, the middle of a graduated arch, FG H, when the air is in a middle-state, between the greatest moisture and the greatest dryness. Under this silk to swing with that, is placed a little table or shelf I, for that part of the silk and shot which is not suspended to rest upon. When the moisture imbibed by the sponge increases its weight, it will raise the index, and also part of the shot, from the table, and vice versa, when the air is dry. Phil. Trans. N. vol. 479. p. 496.

From a series of hygroscopical observations, made with an apparatus of dead wood, described in the Philosophical Transactions, N. vol. 480, Mr. Coniers concludes, 1. That the wood shrinks most in summer, and swells most in winter, but is most liable to change at spring and fall. 2. That this motion happens chiefly in the day-time, there being scarcely any variation in the night. 3. That there is a motion even in dry weather, the wood dwelling in the morning, and shrinking in the afternoon. 4. The wood, by night as well as day, uniformly shrinks when the wind is in the north, north-east, and south, both in winter and summer. 5. That by constant observation of the motion and rest of the wood, with the help of a thermometer, one may tell the situation of the wind without a weather-cock.

He adds that the time of the year may be known by it; for in spring it moves quicker and more in winter; in summer it is more shrunk than in spring; and has less motion in autumn than in summer.

Dr. Hooke's hygrometer was made of the board of a wild oak, A, in a full box, with a dial plate and an index. See his Micrographia, vol. i. p. 260, &c.

An hygrometer of this kind may be constructed in the following manner. Let ABCD (fig. 9.) be a square brass plate, about four inches square, with a ring or circle fixed to it, graduated on the flat and the inner edge. IC represents a very light index of brass or steel, with a small cylindrical lump in its centre, into which is fastened the top of the beam of a wild oak, by a little peg, and the other end of it in another lump, about an inch under the plate, which, having a little hole under C, allows the beam of the oak to come through, in order to carry the hand, and yet keep it in its place, without hindering it to twitl and untwine.

There are also two wires coming down under the middle of the path, which hold a little croos bar, making a small frame to carry the lump that holds the bottom of the oak exposed to the air. The four feet of this instrument, two of which are seen at C, must be about one inch and a quarter long, to keep the frame under the plate from touching any thing which the instrument is set upon. AB, in fig. 10, represents the plate, F and F two of its feet, C and D the little lumps to which the wild oak-headed, CD, is fastened; ef and gh the wires supporting the piece fh, and all together form an open frame, to hold the lump D. The beard passes through the hole h, in order to carry the index i, which points to the degrees on the graduated circle A B.

The following hygrometer was contriv'd by Dr. Halley and Dampier, Pl. p. 9, c. (fig. 11.) is a piece of lignum victoriae, cylindrical at C, P; but in C, P a truncated cone, and screwed like the fusee of a watch, but not tapper. The length of the instrument is about a foot, the cylindrical part an inch in diameter, and half an inch long; the large part of the screw about three quarters of an inch, and the small part half an inch; at each end there are fine steel pivots, bearing on two fine conic holes in brasses in the frame that carries the instrument, that it may turn easily. A sponge, S, hangs by a silk from the cylinder of the instrument, so as to turn by its rising or falling; a weight W, hanging from another silk, coded upon the screw C, keeps the sponge in equilibrio. When the sponge becomes heavier, by imbibing moisture from the air, it runs down, and draws up W; but as W comes up, its string pull advance towards C, so, where, hanging farther from its centre, its power will be so increased, that it will keep the sponge in equilibrio, though its weight be increased. But as the weight rises, it will fly on the scale, D D, how much the sponge is heavier, and consequently the air moister. This instrument will be made still more sensible, when its pivots are supported by four friction wheels. Salt of tartar, or any other salt, or pot-ashes, may be put into the scale of a balance, and used instead of the sponge. Defag. Exp. Phil. vol. ii. p. 300.

In an hygrometer invented and described by Mr. Ferguson, A A A A (fig. 12.) is a frame of wainscot or mahogany, grooved in the longest sides, to hold the panel B B B of white deal board, without pinching it. The panel is about the thickness of a crown-piece, and fifteen inches long croos-wise to the grain of the wood. The middle part projects at C and C, where it is fastened into the frame by two screws; so that this part always remains in the fame place, whilst the rest of the panel expands by moist air towards both ends of the frame, and contracts towards the middle, when the air is dry. To a pin at F is fastened one end of a small flexible cord D E, and the other end goes round the pulley G, and is fixed into the bottom of its groove at h. One end of another small cord, I K, is fixed into the groove of the large pulley H, at a, going round the part at i H, and passing round to M, round a small pulley L, the axis of which is the piece O, lying above it, and secured to the frame at C. To the end of the cord is appended a flattish weight N. The diameters of the pulleys G and L are equal, and about one-tenth of the diameter of H. The distance of the pulleys G, and pin F, will determine the expansion of the panel between F and G: which will cause the pulley, G, to turn backward, and any point in H ten times as much; and in this proportion will the weight N be raised: therefore, if the panel extend one-tenth of an inch by moist air, the pulley L will be turned quite round. As the air grows dry, the panel contracts, the weight N descends, and turns all the pulleys the contrary way. The back of the plate A A, (fig. 13.) is screwed to the other side of the frame, so that the upright edge of the plate may be even with the uppermost part of the frame, and the centre B may be directly over the centre of the pulley G (fig. 12.), on whose axis the index B C (fig. 13.) is fixed, which, by moving on the graduated edge of the plate, indicates the moisture or dryness of the air. The panel should be changed in three or four years. (Phil. Trans. vol. iv. art. 47.) Mr. Smeaton has given the construction of an hygrometer of cord: it is, doubtless, the best that has been published condicted of that substance.

Mr. Smeaton's hygrometer is exhibited in (Plate XIII. fig. 1.) and 2. A B C (fig. 1.) is an orthographic delineation of the whole instrument ten in front, with the box-cover H, which
HYGROMETRY.

Defends the index, &c. from injury, and by a gias expels the scale to view. FG in both figures represents a flaxen cord, about 35 inches long, suspended by the turning peg Π, attached to a loop of brafs wire at A. This cord is that which is called by net makers in London flaxen thread-thread tided, and is between one 20th and one 30th of an inch diameter. It is fixedly boid, and the solution of two pennyweights troy of common salt in one pound avoiduopoe of water, boiled till the whole is reduced to fix ounces avoiduopoe. The cord soaked in this brine is dried, and then stretched, by tying three or four yards of it to two nails against a wall, in a horizontal position, and hanging a weight of a pound or two to the middle. When it has remained in this position for a week or more in a room, it will be fit for use. G I. (fig. 2) are two loops, or long links of brafs-wire, laying hold of the index K L, which is moveable on a small fluid or centre K. The cord FG is kept moderately strained by a weight M, about half a pound avoiduopoe. As the cord lengthens or shortens, the end of the index passes over the scale N Q, diposped in the arc of a circle, and containing 100 equal divisions. This scale is attached to the brafs sliding ruler Q P, which moves on the directing piece R S, fixed by ferews to the board, which makes the frame or base of the whole; and the scale and ruler, N Q P, are retained in any place nearer to or farther from the centre K, by the screw S. Fig. 3, represents in profile the sliding piece and fluid I, which travels on that part of the index next the centre K; and which can, by the two screws of the flad, be retained upon any part of the index that is made parallel, and which is done for three or four inches from the centre, for that purpose. The flad is filled to the edges like the fulcrum of a scale-beam, one being formed on the under-side, and the other upon the upper, as near as possible to one another. A hook formed at the lower end of the wire loops, G I, retains the index by the lowermost end of the flad, while the weight M hangs by a small hook upon the upper edge. By these means the index is kept ready, and the cords strained by the weight, with very little friction or burthen upon the central fluid K.

Fig. 4. is a parallelogram of plate brafs to keep out dust, which is attached to the upper edge of the box-cover H, and serves to shut the part of the cover, necessarily cut away, to give leave for the wire, G I, to travel with the sliding fluid (fig. 3.) nearer to or farther from the centre of the index K. In this (fig 4.) there is a hole a, about one-fifth of an inch diameter, for the wire G I to pass through, in the motion of the index, without touching; b is a slit of a letter size, sufficient for the wire to pass, and allow the cover to come off without deranging the end of the index; c, c, are two small ferews applied to two flats, by which the plate slides lengthways, in order to adapt the hole a to the wire G I, at any place of the fluid I, upon the index K I. This index is 12 inches long, four inches of which, from the extreme end, are fixed so narrow, that any part of them may serve for an index to the divisions of the scale; the scale itself also slides four inches. The directing piece, R S, is parallel to a line drawn from o upon the scale to the centre, K, of the index; consequently, as the attenuated part of the index forms a part of a right line drawn from the fame centre, whenever the index points to o upon the scale, though the scale be removed nearer to or farther from the centre of the index, yet it produces no change in the place to which the index points. When the divided arc of the scale is at 10 inches from the centre, which is its mean distance, then the centre of the arc and the centre of the index are coincident. At other distances, the extremes of which are eight or 12 inches, the centre of the divisions, and the centre of the index, pointing to them, not being coincident, the index cannot move over spaces geometrically proportional to one another in all situations of the scale; yet the whole scale not exceeding 30 degrees of a circle, it will be found, on computation, that the error can never be so great as $\frac{1}{10}$th part of the scale, or one degree of the hygrometer.

For adjusting the instrument, take off the box-cover, and let the instrument nearly upright about a yard from a moderate fire; there let it remain, till the index sinks as low as it will go, froking the cord occasionally between the thumb and finger downwards. When it is become stationary, raise or depress the index by means of the peg at top, till it lies over the point o; then remove the instrument from the fire, and with a camel-hair pencil dipped in warm water, moisten the cord, withoutuffering any drops of wet to fall from it till it is fattened, and the index becomes stationary. If the index lies over the degree marked 100, all is right; if not, slacken the screw S, and slide the scale nearer to or farther from the centre, till the point 100 come under the index, and the instrument is adjusted for use. The intermediate space must then be divided into equal parts. The adjustment may be repeated two or three times a year, or as often as may be judged necessary to adapt the scale to the existing capacity of the cord. If the compass of the flad be not sufficient to effect this, slacken the proper ferews, and move the sliding fluid I nearer to or farther from the centre of the index, as the angle, formed by the index between the points of dry and wet, happens to be too small or too large for the scale. Mr. Smeaton was led by observation to mark the point of 0 dry, 20 the mean, 40 neutral, 70 very moist, and 100 wet. Phil. Trans. vol. xi. part 1. art. 24.

Other instruments of a more delicate and portable nature have since been invented. We may form an idea of the flow and gradual manner by which a cord of this kind losses its power, by the result of a series of experiments made by Mr. Dalton, and published in his Meteorological Essays, 1793. A piece of whip-cord, six yards long, was hung up in a room and thrown over a pulley; it was then stretched by a weight of three ounces for some months; after which an index and a scale of inches and decimals were attached to the end having the weight. A regular series of observations were made on it three times a day for two years, and once a day for three succeeding years. The room was without fire, but not airy.

The results are below; the higher numbers denote greater dryness, all other circumstances being the same.

- November: 10.2
- December: 9.75

Hence
HYGROMETRY.

Hence it appears that a cord, in these circumstances, increases every year in length, but lefts and less each year, and that the range of variation diminishes each year. The quantity, however, is such as to render instruments of Smeaton's construction occasionally adjusted very comparable.

Another still more simple form of this sort of hygrometer consists of a short piece of cord or cat-gut, from four to ten inches, suspended by a hook over a horizontal board; to the lower end of the cord is fixed a horizontal index having a circular graduated scale on the board. As the cord attracts moisture or the contrary, it twists or untwists, and thereby turns the index. On this principle, the Dutch toys, called weather-houses, are made; one end of the index supports a small image of a man, and the other that of a woman; the former appears, or is brought out, in wet weather, and the latter in fair weather.

M. de Luc some time ago constructed an hygrometer of ivory. The part of his hygrometer which is affected by the moisture of the air, is a hollow tube of ivory $a a b$ (fig. 5.), two inches eight lines long and internally two lines and a half in diameter. This tube is open at the end $a$, and closed at $b$, terminating in a point, and the thickness of its side, for the length of two inches, is three lines from the bottom, is but three sixteenths of a line; it is this thin part which does the office of an hygrometer; the remaining part of the cylinder, towards its orifice $a$, must be kept a little thicker, in order to hear the pressure of a tube of glass, about fourteen inches long, the lower end of which is seen at $d e t$. The internal diameter of this tube is about three-eighths of a line, and the outside diameter about two lines, in order that the part $g g$ of a brass piece $f f g g$, through which it passes, and which is to enter into the ivory pipe, be as thick as possible. In order to hinder that part of the tube which incloses the brass piece from being affected by the variations of moisture, it is covered with a brass ferrul $b b i i$. These pieces are united together with gum luc or mutfich, which melts by the heating of the glass and brasses. M. de Luc's reason for chusing ivory for his hygrometer, is, that this matter appeared to him more proper than any other for receiving the impression of the moisture of the air, without suffering thereby any material change. The cylinder made of it becomes more capacious, in proportion as it grows moister; and this is the only principle on which the construction of M. de Luc has also found, that upon letting this cylinder lie for some time in water of an uniform temperature, it swells to a certain point, after which it dilates no farther. This circumstance furnished him with a maximum of humidity; and, consequently, with one point of comparison in the scale of the hygrometer; and this point he has fixed at the temperature of melting ice. For measuring the differences in the capacity of this ivory cylinder, and thereby discovering its different degrees of moisture, M. de Luc makes use of quicksilver, with which he fills the cylinder, and a part of the communicating glass tube. The more capacious this cylinder is, or, which is the same, the moister it is, the lower does the mercury stand in the glass tube, and vice versa. Now M. de Luc has found, that the point of melting the ivory cylinder 5. in being melted in ice, he therefore names or graduates this point $o$ in the scale of his hygrometer; and, consequently, the degrees of this scale are degrees of dryness, counted from below upwards, as the quicksilver rises in the glass tube. To give these degrees a determinate length, and thus to render the hygrometers capable of being compared with each other, M. de Luc employs in constructing them such glass tubes as have been previously prepared, by being made into thermometers, and filled with mercury, so as to ascertain upon

them the points of melting ice and boiling water, and to take exactly the distance between these points by any scale at pleasure. When this is done, the bulb of this preparatory thermometer must be broken, and the quicksilver it contains exactly weighed. It is by knowing the weight of this, together with the distance between the fixed points of the thermometer, that the scale of the hygrometer is determined. *E. gr.* Let the weight of the quicksilver be one ounce, and the distance between the above-mentioned points one thousand parts of a certain scale; then suppose that the quicksilver in the hygrometer to which this tube is to be applied, weighs only half an ounce; this will give a fundamental line, consisting of 500 parts of the same scale. The fundamental line, thus found, is applied to the scale of the hygrometer, beginning at $o$, and measuring it off about four times over, that the whole variation of the instrument may be comprehended. Each of these spaces being afterwards divided into 40 equal parts, gives such degrees as M. de Luc has found most convenient. In general terms, the length of the fundamental line of the hygrometer must be to the interval between the two fixed points of the preparatory thermometer, as the weight of the quicksilver in the hygrometer is to the weight of the quicksilver in that thermometer. This proportion between the scale of the hygrometer, and that of the preparatory thermometer, furnishes an easy method of correcting in this instrument the effects of heat upon the mercury which it contains. It will easily be conceived, from the construction of the scale of this hygrometer, that if its cylinder of ivory was suddenly changed into glass, the instrument would become a true thermometer, in which the interval between the points, answering to melting ice and boiling water, would be divided into 40 parts. If, therefore, a thermometer with a scale similarly divided into 40 parts between the fixed points, be placed near the hygrometer, it will shew immediately the correction to be made on that instrument for its variations as a thermometer, under particular restrictions, which M. de Luc has stated.

The part of the frame of the instrument on which the scale is marked is immovable; so that, before observing the point at which the mercury stands, it may be pulled upwards or downwards, according as the thermometer has risen or fallen with respect to the point of melting ice; and all the indications of the hygrometer can at once be freed from the errors which would arise from the difference in the volume of the quicksilver, on account of the different degrees of heat.

For this purpose, at the top of this scale, there is an index over-against another small scale, marked upon the unmovable part of the frame; the degrees of this small scale are eightieth parts of the fundamental line, and answering to the degrees of the thermometer on the same frame. When the index points to $o$ of the small scale, the thread which indicates upon the tube of the hygrometer the point to which the mercury stands in the melting ice, answers likewise to $o$ in the scale of the hygrometer. See an elaborate account of the principles and advantages of this hygrometer, the particular process of its construction, and observations made with it by M. de Luc, in the Phil. Trans. vol. lxiii. part ii. art. 38.

The instrument, with its frame, is seen in fig. 6. It is mounted on deal, because this wood suffers the least change in the length of its fibres. The lower part of the frame is fitted through the whole length of the ivory pipe, in order that the air may circulate freely round this pipe, and the bulb of an annexed thermometer. The hygrometer is fastened in three parts, viz. at bottom on a small bracket, at top by a tube passing through a piece either of hard wood or...
HYGROMETRY.

or of metal fastened by screws, and chiefly by means of a brazen wire on the neck of the brass piece, which unites the glass with the ivory pipe. This piece is laid in a small plate of a hard wood, which in that place fills a groove originally made through the whole length of the board. To prevent dust from getting through the opening of the tube, it is fixed up in a small ivory case. The scale of the hygrometer is marked upon a deal slip, which slides along the groove just mentioned. This and all the other parts of the frame must be lined with paper, for marking the necessary scales, and this paper is afterwards varnished over. The scale of the hygrometer is carried to the upper point, by means of a knob fixed on a small piece of hard wood or metal screwed to the bottom of the board, and which affords a free passage to the tube of the hygrometer.

Méfius Sauffure and D. Luc have both successfully prosecuted their investigations in the science of hygrometry. The former of these gentlemen wrote an essay on hygrometry, which was published in 1783. In this elaborate, and in many respects excellent work, Sauffure contends for the superiority of human hair, for the purpose of hygrometers. Hair, he finds, after it has been boiled in a weak alkaline lixivium, will expand by moisture nearly 1/4-th of its length, and contract again by dryness; and that it is less liable to lose this effect by time than most other substances, and is moreover, from its tenuity, very quickly reduced to the present state of the atmosphere. On these accounts he gives it the preference to other substances, and constructs his hygrometer with it accordingly. The principle of the construction is to render one end of the hair to a fixed point, and the other to the arm of a small wheel, which carries a fine needle at one extremity; this needle points out, upon a graduated circular arch, the hygrometric degrees. The hair is stretched by a counterpoise of three or four grains, suspended from the same arrow by a fine silk thread. A more particular description of the construction is given by the author, in reference to plate 1, fig. 1, of the essay. See Plate XI. Hydraulics, fig. 7.

The inferior extremity of the hair, a b, is held by the mouth of the screw-pincers, b; these pincers, represented separately in B, terminate in a screw, which enters into the female screw at C: this screw turns continually in an empty screw, and serves to raise or lower the box at pleasure. The other extremity, a, of the hair is held by the inferior mouth of the double moveable pincers, represented separately in A. These pincers, at their lower mouth, take hold of the hair, and at their upper a fine well tempered silver wire, which is wound round the arrow, c, which is represented separately in D F. This arrow, which carries the needle e, marked e in the separate figure, is cut like a screw, and the bottom of the thread is flat and cut square to receive the silver wire fastened to a, and connected to the hair. I was forced to use a silver wire, because, when the hair was fixed to the cylinder and wound round it, it grew rough, and contracted a stiffness, which the counterpoise could not overcome; whereas, a well tempered silver wire always keeps the same flexibility. It was necessary to cut the arrow like a screw, in order that this wire might not be wound upon itself and thicken the arrow, nor take a fixation too oblique and variable. The wire is fixed to the arrow by a small pin F. The other end of the arrow, D, has the form of a pulley, flat at the bottom, to receive a fine flexible wire thread, to which is suspended the counterpoise marked g, in the great figure, and G in the separate figure. This counterpoise intended to stretch the hair, acts in a direction contrary to that of the hair, and of the moveable pincers to which it is fastened. If then it is defined the hair should be stretched with a weight of four grains, it is necessary the counterpoise should weigh four grains more than the pincers. The fame arrow passes on one end through the centre of the dial, and turns in a very small hole upon a true and well polished pivot. The other end has a similar pivot, which is received in a hole made at the end of the arm b of the double square b i, H I. This double square is fixed behind to the dial by the screw l. The dial k e k, divided into 360 degrees, is supported by two ears b, l; these are fastened to two tubes, which surround the cylindrical columns m, m, n. The screws of prehension, r, n, pass through these tubes, and serve to fix the dial, and the arrow attached to it, to any desired height. These two columns which support the dial, are firmly fixed to the base of the hygrometer, which rolls on the four screws w, x, y, z, by which it may be placed in a vertical position. The square column w, which rolls upon the farther cross bar of the base of the hygrometer, carries a box g, to which is fixed a kind of pencil case r, the vacancy of which is of the fame diameter as the cylindrical counterpoise g. When the hygrometer is to be transported from one place to another, and some fear may be entertained that the vibrations of the counterpoise may do harm, the case is raised to receive the counterpoise which is then fixed by the screw prefers a, and the box itself is fixed by another screw i. When the hygrometer is in use, the counterpoise is disengaged and the box lowered, as in the figure. Lastly, there is seen on the top of the instrument a piece of crooked metal x, y, z, which holds together the three columns just described. This piece is pierced in y with a square hole, which is convenient when the hygrometer is to be suffused.

M. de Luc, however contends, in his "Idées sur la Meteorologie, 1786," that hairs, and all other animal or vegetable hygrometric substances taken lengthwise, or in the direction of their fibres, undergo contrary changes from different variations of humidity; that when immersed in water they lengthen first and then shorten; that when they are nearest the extreme of humidity, they shorten with an increscent and lengthen with a diminution of humidity. These observations may be just; but the irregularities happening only in or near one extreme, and being small, may be neglected. Sauffure takes his point of extreme moisture from the air confined under a glass bell, the sides of which are kept moist; De Luc objects to this as not exhibiting the maximum of moisture, and observes, that it lean in an elastic state does not render bodies moist, as is proved by the experience of Mr. Watt, who found that wood, exposed to the lean of a steam-engine, was constantly dried and cracked as if exposed to the fire. This objection can scarcely apply, however, to the case. For the lean in an engine is generally some degrees warmer than the temperature necessary for its support as an elastic fluid, and a degree or two in temperature at the heat of the boiling water, have an infinitely greater effect in drying than they have at the ordinary temperature of the atmosphere. Besides, the point of extreme moisture in a hygrometer should most evidently indicate that state of the atmosphere when evaporation is at a stand, or the air is saturated with moisture without any visible deposition of water. It cannot be supposed that there is any interval between saturation and precipitation. De Luc prefers whale-bone upon the whole for a hygrometer, and of that a small thin slip cut across the grain. The description of his whale-bone hygrometer is given in the 3d vol. of the Philos. Tranac. part ii. as follows.

The frame will be sufficiently known from the figure (fig. 8) therefore, we shall confine ourselves to the description of some particulars. The slip of whale-bone is represented by a b, and at its end, a, is seen a fort of pincers made only of a flattened bent wire, tapering in the part that holds the slip, and prefixed by a sliding ring. The end b is fixed to a moveable
HYGROMETRY.

Mr. Leflie has proposed a new hygrometer, or rather a new method of finding the rate of evaporation of water in the air; it may be seen in Nicholson's Journal, 4th vol. 2, or in the 53d vol. of the Annales de Chimie. It is founded on the principle that evaporation produces cold, and consists of a kind of air-thermometer nicely adjusted, the bulk of which, by being moistened with water, immediately cools to a lower degree in consequence of the evaporation of the water, and the more the quicker the evaporation. Hence a law might be found to indicate, from the degree of cold produced, the rapidity of evaporation. If so, it would be a convenient substitute for the method pointed out in the preceding division. The author has not yet developed the advantages of this instrument so as to bring it into general use.

5. On the dew-point; or that point of temperature at or below which dew is deposited from the atmosphere upon glass or any other smooth surface.—L. Le Roi was the first, according to Sauffure, who made a practice to find the dew-point of the air with hygrometrical views; he used to take a glass nearly full of water; then he gradually put into it ice-cold water, till a dew was deposited on the outside of the glass, and noted the temperature of the water. This temperature may be called the dew-point. Instead of ice-water, Sauffure used pounded sal-ammoniac to cool the water; and a mixture of nitre and sal-ammoniac is still better. Sauffure, however, conceives this expedient insufficient to answer the purposes of an hygrometer; though he allows the value of it taken in conjunction with the others previously described. Of late Mr. Dalton has revived the practice of Le Roi, flown the rationale of the experiment, and founded upon it a new system of hygrometry. See Manchester Memoirs, vol. 5, part 2, pages 535 and 671: also vol. 1, second serie page 252. Some account of his views may be seen under evaporation.

Mr. Dalton first establishes the fact, which indeed had been ably maintained before by De Luc, that the extreme quantity and force of vapour, in a vacuum of given dimensions, are the same as the extreme quantity of force of vapour in the same volume of any kind of air, provided the temperature is the same in both cases. That is, aqueous vapour exerts just the same whether air is present or absent, and its maximum is regulated solely by the temperature, imposing water as a source always to be present. He finds experimentally the utmost force of steam in a vacuum for each temperature, from 0° to 212° of Fahrenheit or upwards. This force is expressed in inches and decimals of mercury, which it can support in a barometer. When the force of steam in the air is required, it may be found from the dew-point; as this manifestly throws the temperature at which the steam of the air begins to be condensed. For instance, suppose the dew-point is 45°; then the extreme force of vapour of that temperature, in a vacuum or in air, is per table, 316 of an inch of mercury, or 1/4th of the force of the atmosphere. Or, in a given volume of air, the weight of the vapour is 3/4th of the weight of the whole, allowing 7 for the specific gravity of pure steam. Hence we see the great importance of the dew-point, as it is the quantity of steam in any given volume of atmospheric air may be determined. Mr. Dalton extends his principles still farther than this.
HYGROMETRY.

The abstract of a series of observations on the dew-point for Manchester, lat. 55° 20' N., which it may be proper to subjoin.

Aug. Mean for 11 days = 56°, but too high for the monthly mean; highest 60°.

Sept. Dew-point above 50° for 6 days; highest 60°.

Oct. Dew-point mostly below 52°, highest 59°.

1801. May. Dew-point above 50° for 4 days; highest 55°.

June. Mean for 10 days 49° 1/2; highest 57 1/2; lowest 39°.

July. Mean for 8 days 53°; highest 56°.

Aug. Mean for 22 days 54 1/2; highest 61°.

Sept. Mean for 14 days 54°; highest 60°.

Oct. Dew-point for 5 days above 50°; highest 57°.

Nov. Highest 54°; lowest 22°.

Dec. Highest 44°; lowest 18°.

* On the 13th, great damage done to potatoes, &c. by the cold which accompanied this remarkably low state of vapour for the season. The dew-point was 46 on the 12th, and 40° on the 14th.

In order to make the observations on the dew-point sufficiently to the purpose of a complete hygrometer, that is, one to denote both the actual quantity of vapour in the air, and the rate at which evaporation is going on, it is necessary to notice the temperature of the air at the time of observation. In a series of meteorological observations this would be almost matter of course. Then the rate of evaporation obtained as above would indicate the drying power of the air at the time. A series of hygrometrical observations might then be thrown into the following form. The numbers in the last column are all multiplied by 100, to make them more suitable to common notation.

Table of the Quantity of aqueous Vapour in the Atmosphere at different Temperatures.

Saufure determined by some very important experiments; the quantity of water in a cubic foot of air at the temperature 66°, both by abstracting the vapour from saturated air, and by saturating previously dried air. The results agree very nearly with the above theory. But when he attempted to ascertain the quantity of water in other temperatures, above and below, by means of his hygrometer, he succeeded in the experiment, but he did not succeed; at least the results will not agree with those deduced as above. He finds the quantities of water too large in the lower temperatures, and too small in the higher. This will be shown by the following table.
In the construction of this table, the force of vapour is taken from the table in the Manchester Memoirs, vol. v. part 2, and it is supposed to result from the pressure of an atmosphere of fluid air, and the vertical column is calculated. The specific gravity of steam is supposed to be .7, that of common air being 1. Sauvages'table in his Hygrometer, 8vo, page 261, is reduced from French grains and feet to English, by multiplying by two, and dividing by three; the grains which he gives as contained in saturated air.

A reduction is also made from Réaumur's scale to Fahrenheit's.

Mr. B. M. Forster has favoured us with the following description of the winding oat-beard hygrometer.

The principal differences in this hygrometer from those usually made of oat-beards are the following.

The graduated circle (Plate XXi. Hydrometers, fig. 2.) is numbered completely round instead of half round each way, as usual. On the top of the oat-beard, the (avena feroles) of Linnaeus, preferred on account of its size to the common oat, is cemented a circular piece of paper A, on which is fixed a tubular piece of straw B, which is capped with another piece of paper C: D is a support to keep the beard upright, made of card paper. On the straw tube, or little cylinder, is fastened a piece of fine linen flinging, on which is hung a pea, to serve as a weight to keep the flinging stretched.

As the oat-beard unswells with moisture, the index (made of straw) moves the same way round as the hand of a watch, and thus moving coils the flinging round the straw tube or axis, by which means the number of revolutions from any time observed may be known, and thus the confusion will be avoided, which is occasioned by the index moving more than once round, which it does in plying from extreme dryness to wet.

The spring may be so placed as to wind up when the index moves the contrary way, that is, from moist to dry. If the maker has care, and in this case the circle must be numbered the contrary way from the above. The oat-beard is fixed, and the index is not to be turned or felt to a certain point, as is the case with the common hygrometer, by a contrivance behind the case. The method of keeping a register to this hygrometer will be thus.

When on the upper part of the axis there is one coil, and the index points at - - - 6, fold down 1 - 6.

If the circle be divided into 100 divisions, reckoning there will be no coil, and the hand at 10; fold down 10.

1 Coils - 10 110,

2 Coils - 10 210, &c.

which, if the circle be large enough, will be a very convenient mode of registering. An account of this instrument was communicated by the inventor to the editor of the Philosophical Magazine. See vol. xi. p. 167.

Kater's hygrometer, as constructed by Mr. Thomas Jones, of Kenton-street. (See fig. 3.) The substance of which this hygrometer is composed, was discovered in India by captain Kater about the year 1800; and it is the Andropogon contoritum of Linnaeus, a species of grass, and is called in the Myfory country, in the Camarca language, "Ooeeox or Idaho." It is best when gathered in the month of January; and should be thoroughly dried in the sun (in India) before it is used. While captain Kater was in India he had one made, which he used with great effect, for the refraction, during a series of observations, which he was then officially employed in making. The instrument was described in the Asiatic Researches, 1803, and was afterwards brought to England in the year 1825. Mr. Thomas Jones then made several on that plan; but it is now laid aside in consequence of a superior method which he has contrived. It may be proper to remark, that this hygrometric substance acts in the same manner as our beard of the English oat, in that it poiffesses much greater durability, and is exceedingly serviceable, making from eight to twelve revolutions from extreme dry to extreme moist, simply of itself, without the means of an increased scale, by wheels and pinions. Each of those revolutions being divided into one hundred parts, gives the observer a scale of from 800 to 1200 parts from dry to moist, being an extent of scale which no other hygrometer poiffesses. The revolutions and parts are seen on a dial plate by means of two small hands. The instrument is of a cylindrical form, one inch and a half in diameter, and two inches long, extremely portable, and not in the least liable to injury in travelling in a carriage. Its sensibility is so great, that it may be truly said to be hardly ever at rest in the open air, particularly in the summer season, when the opening or shutting a door or window, or the approach of a person, is sure to be indicated. Perhaps it may not be amiss to remark, that it is sensibly affected in the hand of a person who may be in health or otherwise. The great sensibility of this instrument makes it particularly valuable where small quantities of moisture, &c., are required to be measured, in chemical or philosophical experiments; likewise for agricultural operations, and iron, steel, and cotton manufactories, &c. &c.

This genus is removed from Ruellia on account of the corolla and tubular calyx, which latter separates moreover into five deep furcations, in consequence of the swelling of the capsule. R. ringens of Linnaeus is one species, for which the Flora Zeylanica of that author, and the Hortus Malabaricus of Rhodea, are, according to Mr. Brown, improperly quoted in the Species Plantarum. Another species, very nearly allied to the former, is H. angulifolia of Brown. "Leaves lanceolate-linear, approximated in pairs, with hairy axils. Upper joints of the stem shorter than the corolla. Found by Sir Joseph Banks in the tropical part of New Holland."

These are cauleiflant plants, with narrow leaves, and axillary, crowded, nearly sessile flowers. The bracteas are small and fringed. Capsule sessile, its valves compressed at the back. Each seed is supported by a small prop, or chaffy appendage.

HYGROPHOBIA, in Medicine, is sometimes used in the same sense with hydropobia.

HYGROSCOPE, compounded of γρος, moist, and 2 Corinth. I observe, or confide, is commonly used in the same sense with hygrometer, which is.

Wolius, however, regarding the etymology of the word, makes some difference. According to him, the hygroscope only shows the alterations of the air in respect of humidity and dryness; but the hygrometer measures them. A hygroscope, therefore, is a less accurate hygrometer.

HYIOTES, f. filiation. See Adoption.

HYKES, a sort of blankets, in great use among the natives of Barbary. They are woven by the women, who make no use of a fluttler therein, but conduct every thread of the web with their fingers. One of these hykes is usually five yards long, and five or six broad, serving the Kabyle as well as Arab, both male and female, for a complete dress in the day, and for his bed and covering in the night. It is a loose and trouble some kind of garment, being frequently

N 3
HYL

frequently disconcerted, and falling on the ground, so that the wearer is every moment to be taking it up, and folding it anew round his body. Dr. Shaw (Trav. p. 286) takes it to be much the same with the peplos, if not with the toga, of the ancients.

HYLEAI, in Ancient Geography, a country of Europe in Scythia.

HYLARCHIUS, formed of ἴλος, matter, and ἀρχή, government, or hylarhic principle, a word by which some authors express what they call a ruling and predilect spirit, which governs and actuates all matter. See PLANTIC.

HYLAS, in Ancient Geography, a river, fountain, and lake in Bithynia.

HYL, in Biography, a musician and dancer, brought up at Rome, under Pyldes the Pautoimim, and passionately beloved by him. He was so vain of his talents, that he arrogantly challenged his master. The challenge was accepted, the day fixed, and all Rome thronged to the theatre. The two actors had to represent Agamemnon. The young Hylas, to add to his stature, had buckles on, which made him taller than usual, and he had a tip-top on his slippers with all his might. The Roman youth were in raptures, and applauded with unbounded fury, crying out that he was divine!

Pyldes then appeared, with a noble and dignified countenance, expressing by his steps and gestures, all the different sentiments which occupied the mind of the great king. The spectators, unanimously impelled by an irrepressible approbation, rapturously cried out that he had obtained the victory.

"Young man," says Pyldes to Hylas, "we had to represent a king who commanded twenty kings; you have made him tall, and I have made him great.

HYL, or Hyle, from ἴλος, which signifies matter, among Athens, is their first matter, or it is matter considered as produced by nature herself; called also chaos.

HYLEG, or HYLE, in ALBROLOGY, an Arabic term for a planet, or for a point of the heavens, which in a man's fancy becomes, as is pretended, the moderator and significator of life.

HYLEGIAL PLACES, among ALBROGERS, are those wherein a planet being found, is qualified to have the government of life attributed to it.

HYLEHROC, in Geography, a very narrow island, about three miles long, on the Baltic, near the S. coast of Lapland. N. lat. 54° 36'. E. long. 11° 32'.

HYLIS, in Ancient Geography, a peninsula, called also the "Promontory of Diomedes," a cape of Liburnia, on the Adriatic sea.

HYLOBI, or HYLOBIANS, compounded of ἴλος, which, besides matter, signifies also wood, forest, and ἐλπις, a fact of Indian philosophers, thus denominated by the Greeks, because they retired to forests, to be more at leisure for the contemplation of nature.

HYLOPATHIANS, formed of ἴλος, matter, and παθή, of ἔρχεσθαι, I suffer. See the following article, and ANAXIMANDRIANS.

HOLOZOISTS, formed of ἴλος, matter, and ἴλος, life, the name of a fact of atheists among the ancient Greek philosophers, who held matter to be animated: maintaining that matter had some natural perception, without animal sensation, or reflection, in itself considered: but that this imperfect life occasioned that organization, whence sensation and reflection afterwards arose. Of these, some hold only one life which they called a plastric life, predilect regularly and invariably over the whole corporeal universe, which they represented as a kind of large plant or vegetable: these were called the cosmoplastic and florical atheists, because the Stoics held such a nature, though many of them supposed it to be the instrument of the Deity. Others thought that every particle of matter was endued with life, and made the mundane plasmatoms to depend upon a certain mixture of chance and plastric or orderly nature united together. These were called the Stratonic, from Strato Lacinianus, a disciple of Theophrastus, called also Physicows, (Cicero, De Nat. Deor. lib. i. cap. 13.) who was first a celebrated Peripatetic, and afterwards formed this new system of atheism for Linus.

Besides these two forms of atheism, some of the ancient philosophers, or Anaximandrians, deriving all things from dead and plastric matter, in the way of qualities and forms, generable and corruptible; and others again adopted the anatomical or Demoricated system, which abridge the production of the universe to atoms and figures. See on this subject Cudworth's Intellectual System, vol. i. chap. 3. Birch's edit. 1743.

HYLOGYNAE and HYLOGYAT, in Ancient Geography, a people of Ethiopia, who lived near one another, and were distinguished by similar manners; they made their habitations in the trees during the night for fear of wild beasts. Disorders has described them.

HYMENAE, in the Ancient Greek Myth. See EPIPLAIA.

HYMEN, in Anatomy, from ivv or, a membrane, a fold of membrane of various sizes in different individuals, closing to a greater or less degree the entrance of the vagina in the virgin, but not found after marriage. See GENERATION.

HYMEN, Imperfect. See VAGINA, Imperfecta.

HYMEN, in Botany, is used for a fine, delicate skin, where-with flowers are inclosed while in the bud, and which bursts as the flower blows or opens.

The term Hymen in this sense, is particularly used in speaking of roses.

HYMEN, in Mythology and Poetry, a term of invocation. Hymen, or Hymenaeus, is properly a fabulous divinity, supposed by the ancients to preside over marriages; and who accordingly was invoked in epithalamiums, and other matrimonial ceremonies, under the formula, Hymen a Hymenaei.

The poets generally crown this deity with a chaplet, sometimes of roses, at other times of sweet marjoram; and represent him, as it were, disdained and enervated with pleasures; drest in a yellow robe, and shoes of the same colour, with a torch in his right-hand, and a flame-coloured veil in his left. Catullus, in one of his epigrams, addresses him thus:

"Cinge tempora flaribus,
Suaveolentia amaranil."

Gen. Ch. Common calyx of many leaves, set in a double row, these leaves are loosely spreading, oblong, obtuse, green and downy at the base, white above, permanent. Cor. compound, tubular, uniform; florets all similar, perfect, fertile, longer than the calyx, funnel-shaped, hairy on the outside; tube thread-shaped; limb five-lobed, lanceolate, acute, revolute. *Stem.* Filaments five, capillary, erect; united anthers cylindrical, tubular, five-touched, as long as the florets. *Pil.* German inferior, tubinate, hairy, crowned with the seed-down, and terminated by a roundish body which the thread-shaped style perforates; stigma on the outside, bifid, revolute. *Peric.* none, except the permanent calyx. *Seeds* solitary, anguated, truncated, elevated by the disk; in two concentric rows, ambibicated, villos, brown; down of it 1.5 approximating, erect, ovate, concave, somewhat torn or entire, membranous, pellucid scales. *Recept.* naked, rather small.

1. H. tubuliflorus. L'Heritier Monogr. — *Calyx* of Carolina, flowering towards the end of autumn. *Receptacle* annual, somewhat tapering, and flabby, a little branched at the sides, of a chestnut colour. *Stem* erect, branching, angulated, rather woolly, two feet high. *Leaves* alternate; radical ones on footstalks; *stem-leaves* gradually sessile, bi-pinnatifid; *segments* lanceolate, acute, green above dotted with little tubercles; downy and grey beneath; spreading. *Flowers* forming a corimb on, white, very fragrant.

The publication of l'Heritier, in which this new genus is founded and delineated, is one of those monographs, of which twelve copies only were printed, mentioned in our account of that author. See l'HERITIER.—Lamark has described the same plant under the name of *Rothia caroliniana*, in the *Journal d'Histoire Nat.*, vol. 1.

Gen. Ch. Fructifications in the margin of the frond, distinct, *Involucrem* two-valved, flattish, straight, opening outwardly, including the column.

Eff. Ch. Fructifications placed at the edge of the frond. *Involucrum* of two valves, opening outwardly.

Obf. “The bivalve involucrum and short column so distinct from the univalve divided involucrum, and long column or style, of the true *Trichomanes*,” have induced Dr. Smith to establish this new genus, in his dissertation on *Ferum*, printed by the academy of Turin.

rocks which it clothes in large tufts in Wales, Westmoreland, and the north of Yorkshire, and also by Powys-court cascade near Dublin, but more especially about Tunbridge, which is its original habitat. It flowers in May and June.—Res creeping, capillary, wiry, throwing out fibres occasionally and producing numerous upright fronds, which curl backwards from drought. Their substance is extremely membranous and pellucid, appearing finely reticulated under a microscope; their segments linear, sharply serrated and furnished with a strong central rib. Fructifications in the place of the first segment, each terminating its appropriate nerve and pointing upwards. involucrum arising from the substance of the leaf, of two deeply concave valves, between which is a short column, beset with small, round, bivalve capsules, each embraced with an elastic ring as in the more common ferns.

2. H. alatum. Wing-tailed Filmy-leaf. Eng. Bot. t. 1207. (H. Tunbridgefe & Sm. Fl. Brit. t. 942.)—“Tronds tritipinate, lobed, decurrent; segments linear, bluntish, entire. Main flilk and branches winged. Fructification oblong, crenate, foliary at the upper edge of the base of each subdivision of the frond.”—Gathered in the county of Kerry, by Mr. Mackay, gardener to the botanic garden at Dublin.—This rare fern manifestly differs from the last in having a larger and more compound frond, and in its main flulk being winged from the very bottom; but more especially in the margin of the segments being always entire, and in the involucrum or calyx being oblong and cylindrical, not obvolute and compressefl, except towards the summit; neither is its margin serrated or toothed, but finely and obtusely crenate. Dr. Smith remarks of this species, “Few of our British plants have been more enveloped in doubt than this; very few could better repay the scrutiny of the curious botanist.” We are now competent to describe it as a new species, for it does not agree with the character of any Hymenophyllum in Dr. Swartz’s Essay on Ferns in Schrader’s Journal. Dr. Swartz has there described 20 species, but the only two British ones known may serve as a sufficient epitome of the genus. We must not omit to mention that Mr. Brown, in his Prodr. Nov. Holl. v. 1. 159, refers the H. alatum to Trichomanes.

HYMENOPTERA, in Entomology, an order instituted by Linnaeus for the reception of those insects which have four membranaceous wings, and the abdomen of the female mostly armed with a sting. The genera are cymips, tenthredo, firex, ichneumon, sphex, amphipolla, ficola, thynnus, lenocopsis, tippa, chalectis, chrysis, velpa, apis, formica, and mutilla.

HYMETTITIUM MARMOR. See MARBLE.

HYMETTUS, in Ancient Geography, a mountain of Attica, S.W. of Athens, and of the Iliss, extending from the S.W. to the N.E., at the distance of a league from the city. It was celebrated for the excellent quality of its honey, which is highly extolled by Strabo, l. i. It was also famous for its marble. On this mountain were altars, one consecrated to Jupiter, and the other to Apollo. See Paufasias, in Attica, c. 32.

HYMN, a long, or ode in honour of God; or a poem proper to be long, composed in honour of some deity. See Ode, and Sonet.

The word is Greek, ὕμνος, hymnos; formed of the verb ὕμνει, ὕμνημαι, I celebrate.

Hymn, on this word, remarks, that hymn is properly a song of joy, full of the praises of God; by which, according to him, it is distinguished from threnos, which is a mourning song, full of lamentation.

The hymns, or odes, of the ancients, generally consisted of three stanzas or couplets; the first called strophæ; the second, antistrophæ; and the last, epode.

St. Hilary, bishop of Poitiers, is said to have been the first that composed hymns to be sung in churches; he was followed by St. Ambrose. Most of those in the Roman breviary were composed by Prudentius. They have been translated into French verse by Meffeurs De Port Royal.

The Te Deum is also commonly called a hymn, though it be not in verse; so also is the Gloria in excelsis.

In the Greek Liturgy there are four kinds of hymns; but then the word is not taken in the sense of a prayer offered in verse, but simply of laud, or praise. The angelic hymn, or Gloria in excelsis, makes the first kind; the triagion, the second; the cherubic hymn, the third; and the hymn of victory and triumph, called epanoeis, the last.

HYMN of Castor, in the Myth of the Ancients. The Lacedemonians, in marching to battle, played on the flute what they called Calloroc Mætas. Some authors pretend that Castor himself invented this hymn, and that from him it had its name; others that Minerva invented the hymn of Castor, and that this air served at first for the Pærich dance.

HYMN of Ayes little to Hermes.

Aristotle honored his friend and kinman, Hermes, prince of Atarneus, with a hymn, or canticle, which is preserved in Athenaeus, and in Diogenes Laertius, for which he is said to have been arraigned at a court of justice, when he was accused of impiously lavishing upon a mortal such honour and praise, as were due only to the gods.

Aristotle's Hymn to Hermes.

“Virtue! thou soure of pure delight,
Whose rugged men can never affright.
The man with courage fir'd;
For thee the sons of Greece have run
To certain ills, which others shun,
And gloriously expir'd."

“When art thy sacred feeds take root,
Immortal are the flow'rs and fruit,
Unfading are the leaves;
Dearer than smiles of parent kind,
Than balmy sleep, or gold refin'd,
The joys thy triumph gives."

“For thee the Twins of mighty Jove,
For thee divine Alcides strove,
From vice the world to free;
For thee Achilles quits the light,
And Ajax plunges into night,
Eternal night, for thee."

“Hermes, the darling of mankind,
Shall leave a deathless name behind
For the untimely slain;
As long as Jove's bright altars blaze,
His worth shall furnish grateful praise,
To all the Muse's train.”

The offence given by Aristotile in this poem, which his enemies denounced a Præan, seems to have been the saying that the actions of his friend would be sung by the Mætas, as long as the worship of Jupiter Hospitales continued. Athenaeus, however, did not regard it as a true Præan, because the characteristical exclamation Io Præan did not occur in any part of it.

HYMN of Battle, a kind of air which was sung by the Greeks when they advanced to battle, and began to charge instead of the flute, which was used at other times. Traces of this custom are still found amongst the Arnauts, inhabitants
ants of Macedonia, now subject to the Turks. These people, stout and bold, like their ancestors, engage with a rapid pace; the chief fings, and his troops answer, whilist they press forward with an accelerated velocity. These hymns ought to be short, and consist of short verses, set to a lively air. Horace speaks in one of his odes of a poet called Tyrtaeus, who, in the wars of Melina, animated by his verses the Lacedaemonians to such a degree, that they thus gained a complete victory. In the time of Thucydides, however, the Lacedaemonians marched in silence to the sound of flutes, and by its cadence regulated their steps, the better to preserve their ranks. It was this, without doubt, which gave Marshal Saxe the first idea of marching to time; one of the best plans that could be devised to perfect the military art.

HYMNIA, in Mythology, a surname given to Diana, under which appellation the was worshipped, and had a temple in Arcadia.

HYMNUM, Lat. insp., Gr. a song in honour of gods or heroes. The difference between a hymn and a canticle consists in this, that the canticle more generally relates to actions, and the hymn to perfections. The first songs of all nations have been canticles or hymns. Orpheus and Linus puffed among the Greeks for the authors of the first hymns, and there remain among the works of Homer a collection of hymns to the gods.

HYNGLOUGH, in Geography, the name given to a small bay on the south coast of Ireland, in the county of Cork, which lies west of Tooz-head, between it and Baltimore.

HYNNERY, a town of Sweden, in the province of Smaland; 45 miles W.S.W. of Wexio.

HYOBANCHE, in Botany, from a, its, b, a hog, and 2x, to choke or strangle; at least it appears by the analogy of Orobanche, which Linnaeus certainly had in view.

Gen. Ch. Cal. Perianth of seven, linear, pointed, cleft leaves, as long as the corolla. Cor. of one petal, ringed, upper lip valved, emarginate; lower lip none. Stam. Filaments four, in pairs, inserted at the base of the corolla, of a middling length; anthers ovate, drooping, bursing on the upper side. Pifl. Germen superior, ovate; style thread-shaped, curved at the top; stigma thickish, obtuse, emarginate. Peric. Capsule roundish, two-celled, Seeds numerous, small.

Obs. This genus is separated from Orobanche on account of the structure of its calyx and corolla.

1. H. fanginaea. Linn. Mant. 253. (Orobanche mauritania, flore pureo; Pet. Gaz. t. 37. f. 4.)—Found at the Cape of Good Hope growing parasitically on other roots. Stem about six inches high, quite simple, woody, imbricated with leaves which are formed of ovate, thickly imbricated, outwardly convex, smooth, obtuse scales. Spike terminal, villose, imbricated with bracteas and flowers, which latter are solitary and sessile. In habit and structure this genus is nearly allied to Orobanche, but is of a blood-red colour throughout.

HYO-GLOSSUS, in Anatomy, a muscle of the tongue. See DEGLUTITION.

HYOIDES, from υ, and ὕος, form, a bone reclambling the Greek letter upsilon in its shape, and connected to the root of the tongue. See DEGLUTITION.

HYO-PHARYNGEUS, a name sometimes given to the middle constrictor pharyngeus muscle. See DEGLUTITION.

Gen. Ch. Cal. Perianth of one leaf, tubular, ventricose below, with a five-cleft, acute mouth, permanent. Cor. of one petal, funnel-shaped; tube cylindrical, short; limb, bright and spreading, five-cleft half way down, its segments obovate, one broader than the rest. Stam. Filaments five, awl-shaped, inclining; anthers roundish. Pfl. Germen roundish; style thread-shaped, as long as the filaments; stigma capitate. Peric. Capsule ovate, obtuse, marked with a line on each side, two-celled, seeming to be formed of two capsules closely approximating; with a lid opening horizontally; receptacles half-ovate, affixed to the partition. Seeds numerous, rugose.

2. H. reticulatus. Egyptian Henbane. Linn. Sp. Pl. 257. (H. flore rubello; Gér. em. 355; f. 5.)—"Stem-leaves on footstalls, finusted, acute; floral-leaves entire. Flowers ventricose." Native of Crete, Syria and Egypt. It flowers in July. —This annual is very similar to the common Henbane, but differs in having its stem-leaves ovate, bent upwards, and smoother on the upper side; the floral-ones feifieolate and entire. Flowers on a very short stalk, bell-shaped, red, beautifully reticulated with dark veins; their tube fowled.

3. H. albif. White Henbane. Linn. Sp. Pl. 257. Gér. em. 355. —"Leaves on footstalls, finusted, obtuse. Flowers feifieolated." —Native of the south of Europe, flowering in August. —This also resembles H. niger in habit and structure, but the leaves are more rounded or obtuse, very soft, clothed with white hairs, as is also the stem. Flowers fewer; lower ones on longer stalks than the upper. Capsule membranaceous, ventricose at the bottom. Seeds numerous, small, kidney-shaped, of a whitish ash-colour.

Linnaeus observed a variety of this species having the throat of the corolla coloured with dark purple and green.

flax, bobbed, dentate, acute. Flowers on flax. Fruit pendulous. —A native of Crete and other parts of the East. It is commonly cultivated in this country, as it flowers almost through the summer, and is extremely ornamental. — Root biennial (perhaps perennial). Leaves roundish, acutely indented on their edges, hairy. Flowers at each joint of the stem, of a bright yellow colour with a dark purple base. Style much longer than the corolla. Alpinus and other authors make two varieties of this, differing only in size and the shade of colour in the corolla.

6. H. pulillus. Dwarf. Sm. 258. (H. pulillus aureus americanus; Pink. 1t. 37. f. 5.) — Stem slender, lanceolate, toothed; floral leaves in pairs, entire. Calyx furnished with spines. — Native of Peru. — Root annual. Stems six inches in height, brittle, hairy. Leaves alternate, on long hairy stalks. Calyx tuberine, ten-angled, nearly the length of the corolla, and broader than its tube, fimbria at top. Corolla yellow with a black throat, divided on the lower side beyond the limb. Stemma declining.

HYSCHAMUS Peruviana, inhab. of Peru, a name by which Dodonæus and many other authors have called the tobacco plant, more usually known by the name nicotiana.

Gen. Ch. Common calyx cylindric-angular, about eight or ten-cleft; petals lanceolate, erect, acute, fimbriate, keeled, equal, calyced at the base with short cleft sepalis. Cor. compound, somewhat laciniate, uniform; each flower hemispheric, proper, one petal, tongue-shaped, linear, truncate, five-toothed. Stamens five, capillary, very short; anthers united, tubular. Fil. German oblong; style thread-like, the length of the stamens; stigma two, reflexed. Petes none; common permanent calyx clofe or spreading. Seed solitary, oblong, membraneous, streaked on one side along the middle, almost the length of the calyx; the marginal ones broadest; down fimbriate, chaffy. Receptacle naked.

Several species of this genus, of which Willdenow reckons eight in all, require revision, nor are the generic characters well defined. In some instances the crown of the seed is encompassed with hairs.

HYOSYRIS, a name given by Pliny and some other authors to the common knapweed, or jaca nigra.

HYO-THyroideus, or Hyoschos, in Anatomy, a muscle passing between the os hyoidei and the thyroid cartilage, and described in the article DEGLUTITION.

HYPACARIS, or Hypocaris, in Ancient Geography, a river of Scythia, which sprang, according to Herodotus, from a lake, and passing through the middle of the country of the Scythian Nomades, discharged itself into the Euxine sea, near the town of Carcinus, forming on the right Hylax and the Curus Achillies.

HYPACTIC MEDICINES, formed of τέρας, Tete, a term used by some authors for cathartic medicines.

HYP.EA, in Ancient Geography, one of the islands called Steepeades, now Eria, situated on the coast of Gallia Narbonensis.

HYP.EPA, a town of Lydia, between the Tmolus and the Caylfier.

HYP.ERIA, a country of the Peloponnese, in Triphylia.

HYPÆTHROS, or HYPÆTHRON, οθηθρόν, formed of θρόνοι, under, and ρηθρα, air, in the Ancient Architecture, a kind of temple, open at the top, and thereby exposed to the air.

The hypathron, according to Vitruvius, is an open building or portico, such as anciently were certain temples that had no roof or covering. Of this we have an instance in the temple of Jupiter Olympus, built by Cononius, a Roman architect at Athens.

Of hypathrons, some were decalified, others pycnophile; but they had all rows of columns within-side, forming a kind of peristyle; which was essential to this sort of temple.

HYPALLAGE, IMMUTATION, a grammatical figure, whereby,
HYPATIA, in Ancient Geography, a town of Triphyllis, E. of Achaea and N. of TYPANAI.

HYPANAI, a town of the Peloponnese in the Elide; probably the same with TYPANAI.

HYPANAI, a town of European Scythia, once named the Bay. According to the ancients it originated in a large lake, called the Sea of the Hyanai.

HYPANAI, or HYPANTE, or HYPANTE, a name which the Greeks give to the feast or purification of the holy Virgin, or the presentation of Jesus in the temple.

The words are Greek, παναί, or παναί, which properly signify humble, and lowly meeting; being compounded of παν, under, beneath, and αί, or α Predicate, meet, meet, against. The denominations are taken from the meeting of old Simeon, and Anna the prophetesses, in the temple, at the time the child Christ Jesus was brought thither.

HYPARNA, in Ancient Geography, a town of Achaia, in Lycia, according to Arris. 

HYPATIA, a town of Greece, and one of the principal towns of Thessaly, according to Apollodorus, Achaia. A.D. 1. 
—Achis, a country of Achaia, on the river Sangar.

HYPATE, or HYPATIA, in the Greek Myth, an epithet by which the Greeks distinguished the lowest tetrachord, and the lowest string of each of the two lowest tetrachords.

HYPATE, HIPPATIA, was a more than the prelambism, See Great Scale and Notation.

HYPATE Major, or HYPATIA, the lowest string of the second tetrachord, which was also the most acute of the first, as the tetrachords were conjunct. See Conjoint.

HYPATE Primus, in HYPATIA, is an interval, so called by M. Henbling, whose ratio is \( \frac{1}{2} = 357 \frac{3}{2} + 7 \frac{1}{2} \), or the Fifth, which is.

HYPATIA, in Biography, a female philosopher of the Ecdatic sect, was the daughter of Theon, a celebrated mathematician of Alexandria, who flourishing in the fourth and fifth centuries. The talents of his daughter were cultivated with great fertility, and she was made mistress of the different branches of polite learning, and became intimately connect, in the sciences of geometry and astronomy, as they were at that day understood. She next applied herself to philosophy, and in order to have excelled all the philosophers of her time. So high was her reputation, that she was strongly solicited to become a public preacher in the school where Ammonius, Hierocles, and other celebrated philosophers taught: and such was her attachment to science, that the yielded to the public voice, and became minister in the schools. Here she explained the principles of philosophy, and endeavoured to reconcile the syllemes of Plato, Aristotle, and other masters. The celebrity of her name attracted scholars from all parts, and she gained the respect and admiration not only of those who formed her auditors in the schools, but the most eminent characters in Alexandria, and was even consulted by the magistrates in cases of importance. She is said, however, to have been intoxicated by the respect which was paid to her from all quarters; that though the excellence of the philosophers of the age in mathematical learning and science, the discovered no pride, and though she was in person exceedingly beautiful, the never yielded to the impulse of vanity, nor ever gave occasion to the slightest suspicion against her chastity. Possessed of such extraordinary accomplishments and virtues, her house became the resort of persons of learning and distinction; but her talents excited the jealousy of some and little minds, and the attentions to which she was indebted for her celebrity proved the occasion of her destruction. Orestes, a man of liberal education, and intimately acquainted with Hypatia, who, from his frequent consultations, was governor of Alexandria, and Cyril, a bishop of great authority, but haughty, violent, and intolerant in the highest degree, filled the patriarchal chair of that city. This prelate, who perhaps did not with to appear the avowed persecutor, inflamed the populace to plunder the property of the Jews, by forcibly expelling them from Alexandria. Orestes, retaking his conduc, laid the affair before the emperor; who, declaring to interfere in the dispute, the city became a scene of frequent tumults and contests between the partisans of the prelate and governor. The intimacy of Orestes with Hypatia, now became a ground of jealousy to Cyril, who felt indignant that his rival should leave it in his power to be benefited by her sage advice, on which account he was calumniated by the bishop's friends among the monks and Christian populace, and at length the fell a sacrifice to their malignity. Not satisfied with her life, they put her to the most extreme torture, and then treated her dead body with the utmost indignity. Hypatia was murdered in the year 415, under the reign of Theodosius II. by the contending parties, if not by the direct instigation, of Cyril, a bishop of whom was falsely called Christianity. The Christian religion teaches everything that is excellent, kind, and praiseworthy, and the actions of malignant priests are not to be imputed to the creed which teaches, but to the corruption of heart, which is but too frequent found in the temples of the world, in ecclesiastical as well as in civil polity. Moretti. Eschyle's Hist. Phil.

HYPATOIDE, in Mycet, a zone, or air, in a low pitch. 

HYPATOIDES, grave founds. See LEPSIS.

HYPATON, DIATOM, See DIATOMS.

HYPATON, System.

HYPATON, in Botany, a name of whose meaning we can discover nothing. Can it have been corrupted from the Hypolytron of Richard and Perfolin, which has a great appearance of being the same genus? For this suggestion we are indebted to Mr. Brown.—Vahl. Enum. v. 2. 283. Brown. Prod. Nov. Holl. v. 1. 219.—Clafa and order, Trandria Monogynia. Nat. Ord. Calamarm, Linn. Opp帚ds, Jull.

Gen. Ch. Cal. Spike closely imbricated on all sides, with obtuse concave scales, one of them to each flower; perianth of two membranous linear valves, nearly as long, and opposite to each scale. Cor. none. Stam. Filaments three; anthers linear. Pilt. German superior, oblong-ovate; style one, cloven, deciduous; stigmas two or three, undivided. Peric. none. Seed solitary, naked, obscurely triangular, without any hairs at the base.

This genus is allied to Kyllingia, with which it agrees in habit. The species in Vahl are four:

HYP

Leaves linear."—Found at Tranquebar. A foot high. 

Spikes white, brown when old.

The roots of all are fibrous and purple. Stems triangular, erect, without joints. Leaves two or three, channelled, rigid, rough-edged, sheathing. Involucrum mostly two-leaved. Spikes terminal, sessile.

To these Mr. Brown adds a fifth.

The stem is slender, triangular.

Gen. Ch. Cal. Periansh small, of two, ovate, acute, crenet, opposite, deciduous leaves. Cor. of four petals, the two exterior ones opposite, broader, trident, obtuse; the two inner alternate with the others, trifid half way down; the middle segment concave, comprefed, erect. Stam. Filaments four, awl-shaped, erect, covered by the middle segment of the inner petals; anthers crenet, long. PI. Ger. superior, oblong, cylindrical; filaments two, very short; flages acute. Peric. Pod long, curved inwards, joined. Seeds glabrefe, comprefed, a single one in each articulation of the seed-vessel.

Obf. The filaments of H. ceratum appear to be tetradrasti. 

Ed. Ch. Calyx of two leaves. Petals four, the two outer ones broader. Fruit a pod.

1. H. procumbens. Linn. Sp. Pl. 181. (Cunnelum cor- 

scutulatum, five Hypocon Clutifi; Gex. em. 1067. 3)—"Pods curved, comprefed, joined. The two larger petals obtusely three-lobed." Native of the south of Europe, and cultivated, by Gerarde, in this country, before 1507. It flowers in June and July, ripening feed in August. 

Rosw simple, annual, fibrous. Leaves chiefly radical, much divided, pale green, with a greyish or glaucous tinge. Stamens several, fender, comprefed, naked at bottom, but bifurcified with a few leaves at the upper part, amongst which the flo- 

ers-flaks appear, each bifurcating a small yellow flower. Pod grooved with longitudinal flacks. Seeds from ten to twenty, dark brown.—H. patens, Willd. Hort. Berol. t. 5. seems not different from this.

Ic. Rar. v. 2. t. 309.—"Pods jointed, comprefed, curved. Petals entire, the outer ones longer and linear-furcate."—A native of dry sand on the shores of Germany. This is scarcely more than a variety of the last, as it differs only in the leaves being shorter and more acutely toothed, with entire and paler petals.

3. H. pendulum. Linn. Sp. Pl. 181. (Cunnelum filique-

sum; Ger. em. 1067. 2)—"Pods drooping, round, cylindrical. The larger petals obtusely three-lobed."—A native of the south of France, flowering in June and July. —Stem more slender, and flanging more crenet than in H. procumbens. Leaves also longer and narrower. Flowers smaller, appearing at the divisions of the branches, they are yellow like 

those of the greater Celandine, but less.

"Pods oblong, round, torulose. The larger petals encrinate, three-lobed." Ammon received seeds of this plant from Dauria, and Miller from Istria; the latter cultivated it here before 1579. This has much the appearance of the leaf in leaf and flower, but its pods grow erect, and are whitish and twisted about.

5. H. immerre. Sm. Prodr. Fl. Græc. n. 358.—Pods curved, comprefed, joined. All the petals broader.— 

Found by Dr. J. Sibbich in the isle of Cyprus. A figure of this species is defined for the Fl. Græc. t. 156. It has the habit of the rot.

Obf. The juice of these plants is of a yellow colour, re-

sembling that of Celandine, and is said to have the fame narcotic effect as opium.

HYPERLATE, from εμα, under, and εω, a fur-tree, fo-

Moncey, Schreb. rather Cældria Mangysta.

Gen. Ch Perfekt Flowers. Cal. Periansh of five (fodem 

four) ovate, concave, spreading, deciduous leaves, two of which are less than the rot. Cor. Petals five, ovate, a little less than the calys., deciduous, with a nectariferous cell about the germen. Stam. Filaments eight, if readings, placed round the base of the germen, the length of the corolla; anthers ovates-cordate. PI. Ger. globoso, superior; fyle short, erect; flages deflexed, triangular, three-fur-

ved, acute. Peric. Drys pullus, roundsh. Seefl. Nut oval, very smooth; kernel solitary. Male Flowers on the fame tree, but in a distinct panicles. Cal. Cor, and Neff, the fame as in the perfect flowers, from the middle of which half arife the Stam. Filaments eight, converging at the base, either erect, reflexed or ascending, broader at the base; anthers ovates-cordate. PI. The triangular rudiment of a germen; fyle awl-shaped, very small.

(Cytisus arboreus, folia obtusus glabri; Sisane Jam. v. 2. 

33.) Found at Jamaica by the river-side under the town and on the red hills very plentifully. This tree has many trunks, each about four or five inches in diameter, covered with a smooth cinnamon-coloured bark. Branches upright. Leaves always three together at the end of a common footstalk, of a yellowish green colour, very smooth, having one middle rib, and some transverse ones. Dr. Browne observes that it is full of slender branches, and furnished with many leaves of the fame texture and grain with those of Lignum Vicie, but remarkably different in form and disposition. He never saw the fruit in a perfect state.

HYPERNEMUS, an epithet applied by authors to barren 

egresses, or such as a few days before the has been troyed by the cock. They are also called αφριανες, and had both 

these names from the winds being supposed to generate them.

HYPER, a Grek word used in the composition of di-

vers terms derived from that language.

The Greek preposition ιερ, hyper, literally signifies above, beyond; and in composition it expresses some excess, or something beyond the significations of the simple word it is jointed with.

HYPER, Supra, below. See Epi.

HYPER-EOLIAN, the penultima in the ace of the fifteen modes in Greek music, of which the fundamental or key-note was a fourth above the Eolian mode. Neither the hyper-eolian, nor the hyper-lydian mode was to ancient as the reft; nor is either of them mentioned by 

Ariosto;
Anitoxenus; and Ptolemy, who admitted only seven modes, comprehended neither of them in his list.

HYPERANTHERA, in Botany, from τήρει, open, and αιιον, an author, so named by Forskall, in allusion to the superior length or projection of two of the flaments. Forsk. 

The hyberbaton, Longinus observes, is no other than a transpositional of sentiments, or words, out of the natural order or method of discourse, and always implies great violence, or strength of passion, which naturally hurries a man out of himself, and distracts him variously. Thucydides is very liberal in hyperbatons.

Obf. The last species has a bivalve legume, and seeds without wings.

1. H. decandra. Willd. n. 1. (Anoma Moringa; Lourie. Cochinich.)—"Flowers decandrous. Leaves bipinnate; lower leaflets ternate. Legumes somewhat octagonal."—A native of many parts of India; observed by Lourie at Bengal. This tree is of a middling size. Branches spreading. Leaves alternate, unequally bipinnate; leaflets obovate, smooth, entire. Flowers white, in scattered panicles. Legume awl-shaped. Seeds furnished with three membranous wings, and arranged in a straight and simple order along the valves.

2. H. Moringa. Willd. n. 2. (Anoma Moringa; Lourie. Cochinich. Guilandina Moringa; Linn. Pl. Sp. 546. Jacq. C. Rar. v. 3. t. 456.)—"Flowers semi-decandrous. Leaves bipinnate, lower leaflets ternate. Legumes triangular."—A native of Ceylon and Egypt. This species very nearly approaches the last in size and habit, but its leaves are opposite, and flowers less brilliant. Legume more than a foot long, triangular, sometimes square. Seeds triangular and winged, disposed in a single row; these are the "Ben-nuts," formerly much used by perfumers for their oil, which absorbs and retains scents very powerfully.

3. H. semidecandra. Willd. n. 3. Val. Symb. v. 1. 30.—"Flowers semi-decandrous. Leaves bipinnate, finely pinnate at the top."—A native of Arabia. Leaves unequally bipinnate, consisting of six or eight pair of opposite leaflets, on short stalks, larger by degrees towards the top, remote, smooth. Flowers in paniculated clusters. The common and partial alypte-flower-altarate.

HYPERBATAON, or HYPERBAMS, in Grammar and Rhetoric, is a transposition, or a figurative construction, inverting the natural and proper order of the terms of a discourse.

The word is ὑπερβατον, or ὑπερβαμα, derived of ὑπ' τηρει, ultra, beyond, and ἓρμον, go, I go.

Vol. XVIII.
opposite to AC, through O, the intersection of AE and DC, will bisect AC.

Let BF cut DE in G. Then, because the parallels DE and AC are cut by three lines drawn through B,

\[ BD : DE :: AC : CF. \]

And because the same parallels are cut by three lines drawn through O,

\[ DE : EG :: AC : AF. \]

Therefore (11. 5. E.)

\[ AC : CF :: AC : AF. \]

Consequently (9. 5. E.) \( AF = FC \).

4. A straight line drawn from the intersection of two tangents of an hyperbola (figs. 3. and 4.), or opposite hyperbolas, through the centre, will bisect the line drawn between the points of contact.

Let TM and TN be two lines touching an hyperbola, or opposite hyperbolas in M and N; then TC, drawn through the centre, will bisect MN. Let the line which touches the curve in M meet the asymptotes in G and H; and the line touching in N, meet the same lines in K and L; join HK and GL. Then the two triangles GCH and LCK are equal (2); take away, or add, the triangle KCH, and the two triangles KGH and KHL will likewise be equal; therefore KH is parallel to LG (39. 1. E.); and MN, which bisects HG and KL (21. Con.), will likewise be parallel to KH and GL (2. 6. E.). Now TC will bisect GL (Lem.), therefore it will also bisect MN parallel to GL.

5. If a tangent of an hyperbola meet a diameter, and an ordinate be applied to the same diameter from the point of contact; then the semi-diameter will be a mean proportion between the segments lying between the centre and the tangent, and the centre and the ordinate.

First let a tangent HB (fig. 5. and 6.) meet a transverse diameter CA, and let HF be an ordinate to the same; draw AM a tangent of the curve to meet BH in M; draw HA and CM cutting AH in O, and HF in N; join AN. Because AH is bisected in O (4), and AM parallel to HF (1. Cor. 16. Con.), it is manifest that AMHN is a parallelogram. Because AM is parallel to HF, therefore

\[ CM : CN :: BA : BF. \]

And because AN is parallel to BH, therefore

\[ CM : CN :: CB : BA. \]

Consequently (11. 5. E.)

\[ CB : BA :: CB : BF. \]

Secondly, let the tangent HB and ordinate HF be drawn to a second diameter CA; draw the diameter CD, conjugate to CA, and therefore parallel to HF; draw also HT parallel to CA, and therefore an ordinate to CD; let HB cut CA in S.

Then (29. Con. et alterando)

\[ CA : CA' :: CF : CD' :: CD' : HF'. \]

But, on account of similar triangles,

\[ CB : BF :: FS : HF, \text{ or } CS : HF :: HF'. \]

But, by the first case, \( CS \times HF = CS \times CT = CD' \); therefore (11. 5. E.)

\[ CA : CA' :: CF : CB : BF. \]

Converting \( CA' : CF' :: CB : CF, \text{ or } CB \times CF : CF'. \]

Therefore \( CA' = CB \times CF \).

6. The difference of the squares of any two conjugate diameters of an hyperbola, is equal to the difference of the squares of the two axes.

Let CD (fig. 7.) be the transverse axis of an hyperbola, and CM any other transverse diameter, and draw the tangents BD, PMQ, limited by the asymptotes; also draw C.R from the centre perpendicular to PQ. Then because the triangles BCD and PCQ are equal (2), the rectangle BC \times CD and PC \times CQ will also be equal (23. 6. E.); but,

\[ 2 BC \cdot CE = BC \cdot CE' - BE' \]

\[ 2 PC \cdot CQ = PC \cdot CQ' - PQ' \} \]

therefore \( BC' + CE' - BE' = PC' + CQ' - PQ' \}

\[ CP' = \]

(because BE and PQ are bisected in D and M (21. Con.))

\[ CP' = \]

Therefore \( CD = BD = CN = MP \).

and BD is half the conjugate axis, and MP half the diameter conjugate to CM.

7. If a parallelogram be completed by drawing straight lines through the extremities of two conjugate diameters of opposite hyperbolas, so as to be parallel to the diameters themselves, that parallelogram will be conically of the same magnitude, and equal to the rectangle contained by the two axes.

Let MN and PQ (fig. 8.) be two conjugate diameters of opposite hyperbolas, and let the parallelogram FHKG be formed by drawing parallels to MN and PQ through the extremities of the same names; then, because HM and MK, as well as FN and NG, are all equal to PC or CQ (Def. 16. Con.); and HK and FG, both parallel to PQ, are tangents of the hyperbolas, it is plain that the four angular points of the parallelogram will be upon the hyperbola, and therefore HCK is always of the same magnitude (2); and consequently the parallelogram FHKG, which is quadruple of the triangle, is conically of the same magnitude. And the same parallelogram is equal to the rectangle contained by the axes; because the parallelogram becomes a rectangle when the conjugate diameters MN and PQ become the two axes of the hyperbola.

8. If NE and MF (fig. 9.), two tangents of opposite hyperbolas, be both parallel to the same diameter CQ, and be intersected by a third tangent DQ, which cuts them in E and F; then CQ' = NE \times MF; and if the semi-diameter CQ be parallel to the tangent DQ, then CQ = DE \times DF.

Join MN, which will pass through the centre C (Cor. 15. Con.), and draw DO parallel to NE and MF, and DR parallel to MN. Then MC and CP are conjugate semi-diameters, and DO is an ordinate to MC, and DR an ordinate to PC; therefore

\[ OC : CN :: CN : CL \]

Converting et Alternando, \( ON : NL :: CN : CL \)

Therefore, by similar triangles

\[ OD, \text{ or } RC : NE :: MF : CS. \]

Consequently \( MF \times NE = RC \times CS = CP' \) (5).

Again,

\[ DE : EN :: CQ : CP \}

\[ DF : MF :: CQ : CP \}

therefore \( DE \times DF = MF \times EN :: CQ' : CP' \}

and because MF \times EN = CP' therefore \( DE \times DF = CQ' \).

9. Two straight lines MF and M (fig. 10.), drawn from any point in the curve of an hyperbola, make equal angles with the tangent MT drawn from the same point.

Let MT meet the transverse axis in T, and draw MK perpendicular to the same axis produced. Then\[ MF = MF = f K - K f' \]

that is, \( (MF + MF) \times (MF - MF) = f f' (fK + Kf) \).
HYPERBOLA.

but \( MF = MF - 2AC \) (42. Con.), \( fK + KF = 2CK \);

therefore \( AC \times \frac{MF + MF}{MF - MF} = CF \times CK \);

Consequently, \( AC : CF :: CK : \frac{MF + MF}{MF - MF} \);

but (5), \( CT : CA :: CA : CK = \frac{MF + MF}{2} \), ex quo,

\[ \text{and, compendo et dividendo} \]

\[ fT : T \cdot MF : MF. \]

Therefore (3. E. \( M \cdot T \)) \( MT \) bisects the angle \( MF \).f.m.

10. If \( MP \) (fig. 10.) touch an hyperbola, and \( MF \) be drawn from the point of contact to either focus, then \( CP \), drawn from the centre parallel to \( MF \), and limited by the tangent, will be equal to \( AC \), half the transverse axis.

Draw \( MF \) to the other focus, and draw \( fP \) meeting \( MF \), produced if necessary, in \( H \); because \( fC = FC \), and \( CP \) is parallel to \( FH \), therefore \( fP = PH \); consequently, since \( MP \) bisects the angle \( fM \) (9), \( MH = \frac{MF}{fC} \); therefore \( FH = MF - MF = AB \) (42. Con.); and \( CP = \frac{1}{2} FH = AC \).

Cor. 1.—The line \( fP \) will be perpendicular to \( MP \).

For \( MP \), which bisects the vertical angle of the isosceles triangle \( fH \) \( M \) \( H \), will cut the base \( MH \) at right angles.

Cor. 2.—If \( fP \) and \( fP \) be drawn from the two foci perpendicular to a tangent of the hyperbola, the points \( P \) and \( P \) will be in the circumference of the circle described upon the transverse axis as a diameter.

11. The rectangle under \( fP \) and \( fA \) (fig. 10.), two perpendiculars drawn to any tangent of the curve, is equal to the square of half the conjugate axis.

For the points \( P \) and \( P \) are in the circumference of the circle described upon the greater axis \( AB \); therefore if \( fP \) meet the circle again in \( O \), the segment \( OP \), which contains a right angle, will be a semi-circle, and \( OC \) and \( CP \) will be one straight line, and the triangles \( fC O \) and \( fC P \) will be equal, and \( AO = \frac{1}{2} fP \). But \( fP \times fO = fP \times fP = fA \times fB = fC \); therefore \( \frac{1}{2} fP \) square half the conjugate axis (Def. 23. Con.).

12. A straight line \( fT \) (fig. 11.) drawn from the intersection of two tangents of an hyperbola, or opposite hyperbolas, to one of the foci, will make equal angles with the lines \( MF \) and \( NF \) drawn from the points of contact to the same focus. Draw \( MH \), \( MF \) to the other focus, and in \( MF \), \( NF \), produced, if necessary, take \( MQ = MF \), and \( NP = NF \); and join \( TP \). Because \( T \) \( N \) bisects the angle \( fN \) (9), and \( NF = NP \), therefore \( TP = \frac{MF}{fT} \); for a like reason \( TQ = TQ \); therefore \( MF = MF \); because \( TQ = TM \), and \( FO = MF - MF \), therefore \( TM = TM \) (42. Con.) Hence it is plain that the angle \( TFM = TFM = TFM \) (81. E.)

Cor. 1.—The angles which \( T \) makes with one tangent, are equal to the angles \( T \) makes with the other tangent.

For the triangles \( MTf \) and \( MQ \) are equal, and the angle \( MTf = \) the angle \( MTQ \); also, the angle \( FPT = \) the angle \( FPT \).

And taking the differences of these equals,

\[ fT = MF = MF ; \]

therefore \( fP = MF = MF \).

And \( NF = NTf \) \( MTf = NTf. \)

Cor. 2.—If two tangents of an hyperbola, drawn from the extremities of a chord passing through the focus, meet in \( T \) (fig. 12.); then \( TF \) will be perpendicular to the chord \( MN \). For the angles \( MFN \), \( NTF \), are in all cases equal; and if \( MF \) and \( FN \) become one right line, each of the angles is a right angle.

13. If \( MN \) (fig. 12.) be any chord drawn through the focus of an hyperbola, and \( PQ \), likewise drawn through the focus, be ordinately applied to the transverse axis, then

\[ MF \times FN = MN \times PO. \]

Draw \( MS \), \( NR \), perpendicular to the transverse axis, and \( NG \), \( PH \), \( MK \), perpendicular to the directrix that corresponds to the focus \( F \). Then (43. Conics)

\[ PF : PH \times PL = \frac{MF}{2} \times \frac{MF}{2} ; \]

in like manner, \( PF : PH : PF = FN : FR \)

(11. E.) and alternando, \( MF = PF = PF = FN = FS \);

whence \( MF \times FN = MN \times PF \); and

\[ MF \times FN = MN \times PO. \]

14. If a tangent of an hyperbola, as \( DE \) (Plate XI., fig. 13.), intersect two perpendiculars drawn from the extremities of the transverse axis in the points \( D \) and \( E \); then two right lines, drawn from these points to one of the foci, as \( F \), will contain a right angle.

Draw \( FM \) to the point in which \( DE \) touches the curve, and produce \( FM \) to \( S \); then, because \( DB \) and \( DM \) are tangents, therefore the angle \( DFM = FDM \) (12).

And, in like manner, because \( AE \) and \( EM \) are tangents, the angle \( AFE = FES \). Therefore the angle \( EFD = \frac{1}{2} \) the sum of the angles \( AFS \) and \( AFM \), or a right angle.

Of Conjugate Hyperbolas.—It has been proved, that if \( MN \) (fig. 14.), limited by the asymptotes of an hyperbola, touch the curve in \( P \), then \( MN \) will be bisected in \( P \) (21. Con.), and the triangle \( MCN \) will be constantly of the same magnitude; whence it follows that, supposing \( MN \) to be drawn so as to make the triangle \( MCN \) always of one constant magnitude, the middle point \( P \) of \( MN \) will be constantly in the curve of an hyperbola, of which \( CP \) and \( CQ \) (\( CQ \) being parallel and equal to \( PM \)) are conjugate semi-diameters, and the lines \( CM \) and \( CN \) are the asymptotes.

Draw \( MG \), in the angle adjacent to \( MCN \), to pass through \( Q \); then the triangle \( MCG \) will be equal to the triangle \( MCN \), and \( Q \) will be the middle of \( MG \); therefore, according to what has been observed, \( Q \) will always be found in the curve of an hyperbola, of which \( MG \) is a tangent, and \( MC \) and \( CG \) are the asymptotes; and this hyperbola is said related to the first one, that the terminations of the feet of the diameters of the one curve are in the other curve, as is plain from what has already been said. Four hyperbolas, comprehending the two we have been describing, and their conjugate opposites, are called conjugate hyperbolas: such curves lie in opposite angles of the same asymptotes, and the extremities of the second diameters of two of the opposite hyperbolas are in the two remaining opposite hyperbolas.

The most remarkable properties of conjugate hyperbolas are as follows:

1. The second diameters of two of the opposite hyperbolas are all transverse diameters of the other two.

2. Two conjugate diameters of two of the opposite hyperbolas are also conjugate diameters of the other two curves.

3. If a parallelogram \( F \) \( F \) \( C \) be completed, by drawing parallels to the asymptotes through any point in one of
four conjugate hyperbolas, as $F$, that parallelogram will be constantly of one and the same magnitude.

For such a parallelogram will be equal to one-fourth of the triangle $MCN$, or to one-fourth of the triangle $MCG$, which is equal to $MCN$.

4. And hence, if from any point $F$, in one of the curves, $FH$ be drawn parallel to one asymptote to meet the other; then $CH \times HF$ will be constantly of the same magnitude.

5. A line $FK$, terminated by two adjacent hyperbolas, and parallel to one asymptote, is bisected by the other asymptote.

For $CH \times HF = CH \times HK$.

It may be remarked, that while opposite hyperbolas must be regarded as two different branches of the same curve, conjugate hyperbolas are two different curves, possessing, indeed, some analogous properties, but really unconnected by the law of continuity. For, in the first place, when a plane cuts two opposite cones, it produces no more than two opposite hyperbolas, without the smallest trace of the conjugate hyperbolas. And in the next place, if we consider the hyperbola as it is determined by an algebraic equation, no such equation can be found that, preserving the same system of the co-ordinates, will comprehend all the four conjugate hyperbolas. Let the curves be defined by two rectangular co-ordinates $x$ and $y$, parallel to the two axes; then, if, in the equation which belongs to two opposite hyperbolas, the ordinate $x$ be necessarily greater than $y$, in the equation of the two conjugate hyperbolas, the same ordinate $x$ will necessarily be less than $y$; a circumstance which plainly excludes the two latter curves from the equation that defines the two frit. Again, if we define the curves by means of two co-ordinates $x$ and $y$, parallel to the asymptotes, which leads to this equation, $a \times b = x \times y$; then, making $x$ and $y$ both positive in one of the angles of the asymptotes, they will become $-x$ and $-y$, in the opposite angles; and in the two angles adjacent to these, they will be $x$ and $-y$, and $-x$ and $y$. Now, the equations $a \times b = x \times y$ and $a \times b = -x \times -y$, which belong to the two opposite hyperbolas, are consistent with one another, but they are both inconsistent with the equations $a \times b = x \times -y$, and $a \times b = -x \times y$, which would belong to the conjugate hyperbolas, if the same system of the co-ordinates were preserved.

Of the Description of a Hyperbola in Planes. — 1. When the transverse axis and the two foci are given (fig. 15.), any number of points in the opposite hyperbolas may be thus found: Take any point $O$, in the transverse axis produced beyond the foci, and describe a triangle upon $FF$ (22. 1. $E.$), that shall have its fides respectably equal to the distances of $O$ from $A$ and $B$, the vertices of the transverse axis; then the vertex of this triangle, $M$ or $m$, will be in one of the hyperbolas; and in this way, may as many points in both curves be found as shall be thought necessary.

When the two axes are given, the foci may be readily found (Cor. Def. 23. $C.$), and then the curves may be described by this method.

2. A hyperbola that has its two axes equal to one another, and the angle of the asymptotes equal to a right angle, is called an equilateral hyperbola; such a curve may be thus described, by finding an indefinite number of points. Let $AB = DD$ be the two semi-axes; in $AB$, produced either way, assume any point $O$, and, having drawn an indefinite perpendicular through $O$, cut $CO$ in $L$ with a circle described from the centre $D$ with the radius $CO$, and let off OP, $O$ upon the perpendicular, each equal to $CL$; then will $P$ and $O$ be points in one of the opposite curves.

3. When the two foci $F$ and $F$, and the transverse axis $AB$ (fig. 16.) are given, the hyperbola may be described by the following mechanical contrivance. Provide a straight ruler, and let it be made to turn round one focus $f$, so as to have its straight edge $fE$ always directed to $f$; take a thread, which is shorter than the whole length of the ruler, by the length of the transverse axis $AB$, and having fixed one end of the thread in the other focus $f$, attach the other end to the extremity of the ruler at $E$; then if the ruler be turned round about $f$, while the thread is stretched tight by a pin $P$ which slides along the straight edge of the ruler, the point of the pin will trace the hyperbola required. For the excess of $fP$ above $PF$ is equal to the excess of the whole ruler above the whole length of the thread; that is, to the transverse axis $AB$.

4. When the directrix $AM$ (fig. 17.), the corresponding focus $F$, and the vertex $V$ are given; from $V$, as a centre with the distance $VF$, describe a circle, and it will cut the directrix in a point, as $H$; for $FA$ cuts the directrix at right angles, and $VF$ is greater than $VA$ (43. Con.): join $VH$, and provide a ruler $MEN$, with two straight edges, making an angle equal to the angle $VHA$, and place it on the same side of the directrix $MA$ with the focus $F$, so that the edge $ME$ may be in the direction of $MA$, and the other edge $EN$ may be turned toward $F$; fix one end of a thread, which is equal in length to $EN$ in $F$, and attach the other end to $N$: then, if the thread be stretched tight by a pin $P$, which slides along $EN$, the point of that pin will describe the hyperbola required. For, draw $PR$ perpendicular to the directrix, then $PE = PF$; and, because the angles $MEN$ and $AHV$ are equal, by similar triangles $PE$ or $PF = PR = VH$ or $VF = VA$.

Therefore $P$ describes the hyperbola required (43. Con.)

Of the Area of the Hyperbola. — In the treating of the ellipse we have shown that the area of a whole ellipse, or of any segment of it, has to the area of the whole circle described on the transverse axis, or to the corresponding segment of that circle, the same proportion that the conjugate axis has to the transverse axis; and the same reasoning by which this area is treated will apply equally to any two curves whatever have their ordinates answering to the same abscissae where the same proportion: whence it follows, that the constant proportion of the co-ordinates will be that of the areas taken between the same limits. Now, if we suppose any number of hyperbolas to be described on the same transverse axis, then as it is easy to prove, the ordinates of these curves drawn to the common axis, answering to the same abscissae, will be proportional to the second axis of the several curves: and therefore, according to what has been observed, the hyperbolic areas cut off by the ordinates will be proportional to the second axis. This proposition does not, indeed, enable us to square the hyperbolic spaces: but we learn from it that the problem will be accomplished generally for all hyperbolas, if we can find the quadrature of any one in particular, as the equilateral hyperbola, which is the simplest of all.

In further treating of the quadrature of the hyperbola, we shall consider the area contained between the curve and its asymptote, and shall begin with shewing that the spaces comprehended between the ordinates are the measures of the ratio of the abscissae taken on the asymptotes; in other words, that the asymptotic spaces are the logarithms of the abscissae.

1. If through $F$ and $G$ (fig. 18.) two points assumed in a hyperbola, two ordinates $TH$ and $GK$ be drawn parallel
HYPERBOLA.

to one asymptote to cut the other in H and K; then the hyperbolic factor FCG will be equal to the mixtilinear space FHG.

For the triangle CFH will be equal to the triangle CGK, and when these are taken from the space CFGK, the remains, which are the factor FCG and the space FHG, will likewise be equal.

1. If the abscissæ CH, CK, CM, be taken in continued proportion, the asymptotic spaces FHG, GKML will be equal.

Draw FL, CF, CG, CL, and let CG cut FH in N, FL in O, and ML produced in P. Because CH, CL, CM are in continued proportion, therefore HN, GK, and PM will also be in continued proportion. Again, L M : K G :: C K : C M (Cor. i.)

by similar triangles, G K : M P :: C K : C M ; therefore L M : K G :: G K : M P.

And, because HN, KG, and PM were before shown to be in continued proportion, therefore LM = HN. In like manner, it may be shown that FH = PM. Therefore PL = FN, and FL will be bisected in O. Therefore every line drawn in the hyperbola parallel to FL will be bisected by the diameter CG (15. Con. i) and hence is easy to infer that the hyperbolic segment cut off by FL will be bisected by GO. And because CO likewise bisects the triangle FCL, it is plain that the factors FCG and GCL are equal; and consequently so are the spaces FHG and GKML, which are equal to the factors.

2. If the ratio of the abscissæ CG and CF (fig. 19.) be equal to the ratio of the abscissæ CD and CF, then will the asymptotic spaces KGHLM and EDFL, comprehended between the ordinates, be equal.

For we take CS a mean proportional between CG and CF, it will also be a mean proportional between CH and CD. Therefore the space KGRS = space RFSFL, and the space LHRSC = space RFSED: consequently the space KGRH = space RFSF.

3. The asymptotic spaces comprehended between the ordinates are the means of the ratios of the abscissæ.

Let the ratio of CB to CM be a small ratio, and suppose that of CG to CF to be an exact multiple of the ratio of CB to CM; then, according to what has been shown, it is plain that the asymptotic space KGF will be the like multiple of the space ABCMN. Now, the ratio of CB to CM may be taken so small that all other ratios may be considered as exact multiples of it; and then the corresponding hyperbolic spaces will be the like multiples of the area ABCMN: which proves what was proposed.

What has here been demonstrated of the abscissæ and the asymptotic spaces is exactly the same relation that subsists between numbers and their logarithms: and therefore if the abscissæ be taken to represent the series of natural numbers, the hyperbolic spaces comprehended between the ordinates will be proportional to the logarithms of the numbers.

5. Supposing the abscissæ to be given, it is proposed to investigate a series for the asymptotic space in the equilateral hyperbola.

The vertex of the hyperbola being at A, let the ordinate AB = BC = 1, BF = x, and put z to represent the hyperbolic area A B F I; between CB and CF interpolate as many mean proportionals Cm, Cp, &c. as there are units in the whole number denoted by i: then, according to what has been proved, all the areas A B m n, m n C K, &c. of which the number is i, will be equal; and therefore the space A B m n = \(1\) \(+\) \(x\) \(^{i}\); but, because C F = \(1\) \(+\) \(x\), therefore

fore C m = \((1 + x)^{i}\); and B m \(\times\) B A = \((1 + x)^{i} - 1\): now when i is a very great number, and consequently B m very small, the rectangle B m \(\times\) B A may be considered as equivalent to the hyperbolic space A B m n; therefore \(z\) \(=\) \(i\) \(\times\) \(\left\{\left(1 + x^{2}\right)^{i} - 1\right\}\); and expanding the radical by the binomial theorem, we get

\[z = x - \frac{1}{2} \cdot x^{2} + \frac{1}{3} \cdot x^{3} - \frac{1}{4} \cdot x^{4} + &c.\]

This expression of the value of z is greater than the truth for all values of i, but it differs less and less from the truth as is taken greater and greater; and therefore, by taking the limit to which the expression confluently approaches as i increases, we shall have accurately

\[z = x - \frac{1}{2} \cdot x^{2} + \frac{1}{3} \cdot x^{3} - \frac{1}{4} \cdot x^{4} + &c.\]

This is the series which Mercator invented for the quadrature of the hyperbola, and which he published (in 1667) in his Logarithmotechnia. If the area denoted by z lie on the other side of A B, and B Z = x, then it may be shown, in the same manner as before, that z = \(i\) \(\times\) \(\left\{1 - (1 - x)^{i}\right\}\); and, by expanding and taking the limit we shall get

\[z = x + \frac{1}{2} \cdot x^{2} + \frac{1}{3} \cdot x^{3} + \frac{1}{4} \cdot x^{4} + &c.\]

This series, which may appear to be a very easy extension of Mercator's invention, was first given by Dr. Wallis of Oxford, in a letter to Lord Brouncker, published in the third volume of the Philosophical Transactions.

The same investigation will apply to any hyperbola (fig. 20.): for preferring the same denominations as before, we shall have the space A B m n = \(\frac{z}{i}\); and if m denote the fine of the angle of the asymptotes, then the space A B m n = m \(\times\) A B \(\times\) m B = m \(\times\) \(\left\{1 - (1 - x)^{i}\right\}\); therefore

\[z = m \times \left\{1 - \frac{1}{2} \cdot x^{2} + \frac{1}{3} \cdot x^{3} - \frac{1}{4} \cdot x^{4} + &c.\right\}\]

And in like manner when the area is on the other side of the ordinate A B, we shall have

\[z = m \times \left\{1 + \frac{1}{2} \cdot x^{2} + \frac{1}{3} \cdot x^{3} + \frac{1}{4} \cdot x^{4} + &c.\right\}\]

It readily follows from what has been proved, that, in different hyperbolas (fig. 22. 19 and 20.), if we take CF to C B in the same proportion, the asymptotic spaces A B F I, or the equivalent factors A C I, will be proportional to the fines of the angles formed by the asymptotes: this supposes that C B is unit in all the hyperbolas; when this is not the case, the space of every hyperbola will be proportional to the square of B C multiplied by the fine of the angle of the asymptotes, or, which is an equivalent space, to half the product of the two axes of the curve.

It has already been remarked that the hyperbolic trapezia, or sectors, bear the same relation to the corresponding abscissæ, that the logarithms of numbers do to the numbers themselves; and by taking m, or the fine of the angle contained by the asymptotes of a proper magnitude, the hyperbolic trapezia or sectors will be measured by the very same numbers as the logarithms in any proposed system. Thus in the equilateral hyperbola, when m = 1, the hyperbolic spaces agree in numerical value with the logarithms.
HYPERBOLA.

The logarithms of Napier's system; and if \( m = \frac{1}{2} \), the hyperbolic spaces will be equivalent to the logarithms of Briggs's system, which are those contained in the tables in common use. From what has now been said we derive an easy rule for computing the area of any hyperbola by means of a table of logarithms. Let the semi-transverse axis of an hyperbola be \( a \) (fig. 20.), the semi-conjugate \( b \), the absciss of the transverse \( CX = y \); then the ordinate \( XI = \frac{b}{a} \sqrt{y^2 - a^2} \); and if \( XI \) cut the asymptotes in \( O \) and \( E \), then

\[
\text{XO} = \frac{b}{a} \cdot y; \text{therefore} \ I O = \frac{b}{a} \cdot (y + \sqrt{y^2 - a^2}) \quad \text{now} \quad I E : E F :: A Y : B Y; \text{or} \quad B C :: O I : C F; \quad \text{therefore} \quad A Y = \frac{b}{a} \cdot \left(y + \frac{\sqrt{y^2 - a^2}}{a}\right) \quad \text{CF} \quad \text{of value} \quad \frac{C F}{B C} \text{when} \quad B C \text{is unit} \quad \text{then} \quad \text{the hyperbolic trapezium} \quad \text{ABFI} \text{I}, \quad \text{or the equivalent sector \( A C I \)}, \text{will be equal to} \quad \frac{a \times b}{2} \times \text{Napier's logarithm of} \quad \frac{y + \sqrt{y^2 - a^2}}{a}; \quad \text{or if} \quad M = \frac{1}{2} \quad \text{the same space will be equal to} \quad \frac{a \times b}{2 \cdot M} \times \text{Briggs's logarithm of} \quad \frac{y + \sqrt{y^2 - a^2}}{a}.

With regard to the area \( X A I \), it is the difference of the triangle \( I C X \) and the sector \( A C I \).

Napier's logarithms, which are expressed by the sectors, or asymptotic trapeziums of an equilateral hyperbola, in which \( CB \) is unit, have obtained the appellation of hyperbolic logarithms; but they do not seem to be better entitled to this name than Briggs's logarithms, which are equivalent to the sectors, or asymptotic trapeziums of the hyperbola, in which \( BC \) is unit, and the line of the angle of the asymptotes \( = \frac{1}{2} \). Nay, what is more, the latter sort of logarithms may be expressed by the areas of an equilateral hyperbola, as well as the former: for this purpose we have only to make \( BC = \frac{1}{2} \); and the sector \( A C I \), or the trapezium \( ABFI \), will be equal to Briggs's logarithm of the number equal to \( \frac{BC}{BC} \).

6. We shall now finish what we have to say on the quadrature of the hyperbola with considering the inverse problem, for determining the absciss when the hyperbolic area is given; or, which is the same thing, for determining the number when the logarithm is given. Now, according to what has already been shewn, we have, in a hyperbola that has the line of the angle of the asymptotes \( = m, \quad z = m \times x \times \left(1 + \frac{x}{1 + x}\right); \quad \text{and, by expanding by the binomial theorem, we get} \quad 1 + x = 1 + \frac{x}{m} + \frac{i - 1}{2} \cdot \frac{z}{m^2} + \frac{i - 2}{2} \cdot \frac{z^2}{m^3} \quad \text{and \( z^3 \), \( z^4 \), \( i - 3 \), \( i - 4 \), \( m^4 \), \( m^5 \), \&c. \quad \text{This equation is not rigorously exact for any value of} \quad i, \quad \text{but it is the more nearly true, the greater is the number that} \quad i \quad \text{stands for; and therefore when we take the limit to which the series continually approaches, we shall have accurately} \quad 1 + x = 1 + \frac{x}{m} + \frac{1}{1 \cdot 2 \cdot 3} \cdot \frac{z}{m^2} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} \cdot \frac{z^2}{m^3} \quad \text{and if the area} \quad z \quad \text{be taken on the other side of the ordinate \( A B \), then, in like manner,} \quad 1 - x = 1 - \frac{z}{m} + \frac{1}{1 \cdot 2} \cdot \frac{z}{m^2} + \frac{1}{1 \cdot 2 \cdot 3} \cdot \frac{z^2}{m^3} + \&c.

Of the Rectification of the Hyperbola. Let \( CB \) (fig. 20.) the semi-transverse axis of an hyperbola, be unit, the distance of the focus from the centre \( \text{CF} = \epsilon \); and consequently the semi-conjugate axis \( = \sqrt{\epsilon^2 - 1} = CD \); let \( CP \), an absciss of the transverse axis, \( = x \); the corresponding ordinate \( MP = \gamma \); and draw \( MT \) a tangent of the curve; then, by the property of the curve, we have

\[
\text{CB} :: \text{CD} :: \text{CP} \quad \text{or} \quad 1: \epsilon - 1 :: x^2 - 1 :: \gamma.
\]

hence \( y = \sqrt{\epsilon^2 - 1} \cdot x^2 - 1 \). Let the length of the arc \( MB \) of the hyperbola be denoted by \( H \); then

\[
H = \sqrt{x^2 + y^2} = x \cdot \sqrt{1 + \frac{(\epsilon - 1)^2}{x^2 - 1}} \cdot \frac{\sqrt{\epsilon^2 - 1}}{x^2 - 1}.
\]

If the tangent \( MT \) cut the transverse in \( T \), then \( CT \times CP = CB \); hence \( CT = \frac{x}{\epsilon} \); and \( TP = x - \frac{1}{\epsilon} \cdot x = x^2 - 1 \); therefore \( MT = \sqrt{TP^2 + MP^2} = \frac{x^2 - 1}{\sqrt{\epsilon^2 - 1}} \). Put \( \tau = MT \), then by taking the fluxions in the value of \( \tau \), we shall get

\[
\tau = \frac{x}{\sqrt{\epsilon^2 - 1}} \cdot \frac{x^2 - 1}{\sqrt{x^2 - 1}} \quad \text{and} \quad \tau = \frac{\sqrt{\epsilon^2 - 1}}{x^2 - 1}.
\]

the rectification of the hyperbola is reduced to the investigation of the fluent of \( \frac{\sqrt{\epsilon^2 - 1}}{x^2 - 1} \), generated while the absciss increases from unit to any indefinite value; for it is clear from what has been proved, that this fluent will express the difference between the hyperbolic arc \( MB \) and its tangent \( MT \). And because a tangent of the hyperbola approaches indefinitely to the asymptote as the point of contact recedes from the vertex, we may likewise infer from what has been said, that the whole fluent generated while \( x \) increases from being equal to unit to be infinitely great, is equivalent to the excess of the asymptote above the curve, when both are indefinitely extended: this last case being the most interesting one of the problem, we shall principally have it in view in what we have farther to add on this subject.

Let \( \sqrt{x^2 - 1} = \tan \epsilon \), and while \( x \) increases from \( 1 \) to be infinitely great, the arc \( \phi \) will increase from \( 0 \) to a quadrant, or \( \frac{\epsilon}{2} \) (denoting \( 0.14159 \), &c.) then \( x = \frac{1}{\cos \phi} \)

\[
\sqrt{x^2 - 1} = \tan \phi \quad \text{and} \quad \phi = \frac{\sin \phi}{\cos \phi} \quad \text{therefore by substitution}
\]

\[
\tau - H = \int \frac{x}{\sqrt{x^2 - 1}} = \int \frac{\sin \phi}{\cos \phi} \quad \text{and, because} \quad \sin \phi = \frac{x}{\sqrt{x^2 - 1}} \quad \text{and} \quad \cos \phi = \frac{1}{\cos \phi} \quad \text{therefore}
\]

\[
\tau - H = \frac{1}{2} \int \frac{1}{\sqrt{x^2 - 1}} = \frac{\sin \phi}{\cos \phi} \quad \text{therefore}
\]

\[
\tau - H = \frac{1}{2} \int \frac{1}{\sqrt{x^2 - 1}} = \frac{1}{2} \int \frac{1}{\sqrt{x^2 - 1}}
\]

affirm.
assumed, \( a^2 + b^2 = c^2 - \frac{1}{4} \); \( 2ab = \frac{1}{2} \); then \( a + b = c \),

\[
a - b = \sqrt{c^2 - 1}; \quad a = \frac{\epsilon + \sqrt{\epsilon^2 - 1}}{2}
\]

\[
b = \frac{\epsilon - \sqrt{\epsilon^2 - 1}}{2}; \quad \text{consequently, } \sqrt{c^2 - 1} - \frac{1}{4} \text{ col. } 2 \phi
\]

\[
(\text{putting } f = \frac{b}{a})
\]

\[
a = \frac{\epsilon + \sqrt{\epsilon^2 - 1}}{2}
\]

\[
b = \frac{\epsilon - \sqrt{\epsilon^2 - 1}}{2}
\]

\[
\text{and } a + b = c, \quad \text{then } \text{col. } 2 \phi
\]

\[
\text{again, let } \Delta = \frac{\epsilon}{2} + \frac{\epsilon}{2} = \frac{\epsilon^2 - 1}{2}; \quad \text{and } \frac{1}{\Delta} = \frac{\epsilon}{2}
\]

\[
- \frac{1}{2} \left( \frac{\epsilon}{2} - 1 \right) \text{; therefore } \tau = H = \frac{1}{a^2}
\]

\[
\int \frac{(1 - \cos 2\phi)}{f} \, d\phi
\]

\[
\frac{1}{\Delta} = \frac{\epsilon + \sqrt{\epsilon^2 - 1}}{2}, \quad \text{and } \frac{(\epsilon - 1)^2}{4} = \frac{\epsilon}{2} + \sqrt{\epsilon^2 - 1}
\]

\[
\tau = H = \frac{\epsilon}{2} + \frac{\sqrt{\epsilon^2 - 1}}{2} \times \int \frac{1}{\Delta} \, d\phi = \frac{2}{\epsilon^2 - 1}
\]

\[
\Delta = A \phi + A \psi \text{ col. } 2 \phi + A \phi \text{ col. } 3 \phi + \text{c.c.}
\]

\[
\frac{1}{\Delta} = B \phi + B \psi \text{ col. } 2 \phi + B \phi \text{ col. } 3 \phi + \text{c.c.}
\]

then, taking the whole fluents from \( \varphi = 0 \) to \( \varphi = \frac{\pi}{2} \), we have \( f \Delta \varphi = \frac{\pi}{4} \), and \( \int \frac{1}{\Delta} \, d\phi = \frac{\pi}{2} \).

with regard to \( A \phi \) and \( B \phi \), they will be found by these series, viz.

\[
A \phi = 1 + \left( \frac{1}{4} \right) \frac{1}{\phi} + \left( \frac{1}{2} \right)^2 \phi + \left( \frac{1}{2} \right)^3 \phi^2 + \text{c.c.}
\]

\[
B \phi = 1 + \left( \frac{1}{4} \right) \frac{1}{\phi} + \left( \frac{1}{2} \right)^2 \phi + \left( \frac{1}{2} \right)^3 \phi^2 + \text{c.c.}
\]

and thus we get the following values of the excess of the asymptote above the hyperbolic curve, when both are infinitely extended, viz.

\[
\frac{\pi}{2} \times \left\{ \frac{\epsilon}{2} + \frac{\sqrt{\epsilon^2 - 1}}{2}, A \phi - \frac{2}{\epsilon} (\epsilon - 1) \frac{\epsilon}{2} + \sqrt{\epsilon^2 - 1}, B \phi \right\}
\]

and this expression is, in most cases, very commodious for computation, because, on account of the smallness of \( f' = \frac{\epsilon - \sqrt{\epsilon^2 - 1}}{2} \), the series for \( A \phi \) and \( B \phi \) converge very rapidly.

**Hyperbola, Acute.** An hyperbola whose asymptotes make an acute angle.

**Hyperbola, Oblique.** This has one of its infinite legs inscribed, and the other circumscribed. See **Oblique**.

**Hyperbola, Equilateral or Rectangular.** Is that wherein the conjugate axes are equal, and whose asymptotes make a right angle. Since the parameter is a third proportional to the conjugate axis, it is also equal to the axis; wherefore, if in the equation \( x^2 = \frac{b}{a} + \frac{b}{a} \), expressing the nature of the hyperbola, you suppose \( b = a \); the equation \( y^2 = ax + x \), will express the nature of the equilateral hyperbola. And hence the abscissae of the ordinates \( y^2 \) and \( \alpha \) are to each other as \( a \alpha + x \) and \( \alpha \psi + \psi' \); that is, as the rectangles of the abscissae into right lines composed of the abscissae and parameter. See **Hyperbola, supra**.

**Hyperbolas, Infinite.** Or **Hyperbolas of the higher kind** are those defined by the equation \( x^2 + x^2 = \frac{(a + x)}{a} \). Hence in the infinite hyperbolas \( a \psi + \psi' = b \phi \); \( b \phi = \frac{(a + x)}{a} \); \( b \phi = \frac{(a + z)}{a} \); that is \( \frac{\psi}{a} + \psi' = \psi + \psi' ; \frac{a}{a} \psi = \frac{a + x}{a} \). See **Hyperbologid**.

As the hyperbola of the first kind, or order, has two asymptotes; that of the second kind, or order, has three; that of the third four, &c.

In respect of these, the hyperbola of the first kind is called the **Asymptotic or Contour** hyperbola; it is thus called in contradistinction to the hyperbolas of the higher kinds. It is called hyperbola from \( \beta \phi = \alpha \phi \); *to exceed*, because in this curve the square of the ordinate \( y^2 \) is equal to \( b \psi + a \phi \), and therefore exceeds the product of the parameter \( b \phi \) by the absciss \( a \phi \).

**Hyperbola, Inscribed.** See **Inscribed**.

**Hyperbola, for the locus of, see **Locus**.

**Hyperbola, for the quadrature of, see **Quadrature** and **Hyperbola, supra**.

**Hyperbolas, Conjugated.** A name given to four hyperbolas, when the first and second axes of two opposite hyperbolas are the second and first axes of two other opposite hyperbolas. See **Hyperbola, supra**.

**Hyperbolas of all degrees may be expressed by the equation** \( x^2 = \frac{a}{b} + \frac{a}{b} \), where \( a \) is a given quantity, \( x \) an abscissa taken on the asymptote, and \( y \) an ordinate to the asymptote.

**Hyperbolæon.** The hyperbolæon tetrachord was the point acute of the five tetrachords in the Greek syllab. This word is the generic name of the plural subtantive \( \beta \phi \); *summits, extremes*; the most acute sounds being at the summit of the ref. **Hypermelos**, \( \psi \phi \psi \psi \alpha \psi \alpha \psi \), *figuratia*, formed of the verb \( \psi \phi \psi \alpha \psi \alpha \psi \); *to exceed*, in *Rhetoric*, a figure, whereby the truth and reality of things are either excessively enlarged or diminished. See **Exaggeration**.

The character of an hyperbole is to exaggerate or extenuate the idea of the thing spoken of, beyond the bounds of truth, or even probability. As, he ran faster than the wind; he went slower than a tortoise, &c.

Hyperboles, says Seneca, lie without deceiving; they lead the mind to truth by fiction; they convey the sentiment intended, though by expressing it in terms which render it incredible. The hyperbole promiseth too much, in order to make you conceive enough. There is nothing finity in an hyperbole, when it is \( \psi \phi \psi \alpha \psi \alpha \psi \), as Quintilian says, provided that it be not \( \psi \phi \psi \alpha \psi \alpha \psi \).

Aristotle observes, that hyperboles are the favourite figures of young authors, who love excess and exaggeration; but that philosophers should not use them without a great deal of reserve.

The pitch to which an hyperbole may be carried, is a point of great delicacy; to carry it too far is to destroy it; it is of the nature of a bow-string, which by immoderate tension,
tenity, slackness; and frequently has an effect quite contrary to that intended. Longinus.

Those hyperbolas are bell, which are latent, and are not taken for hyperbolas. For this reason, they should scarcely ever be used but in a passion; and in the middle of some important incident: such as the hyperbola of Herodotus speaking of the Lacedaemonians, who fought at Thermopylae: "They defended themselves, for some time, with the arms that were left them, and at last with their hands and teeth; till the barbarians, continually shooting, buried them, as it were, with their arrows." Now what likelihood is there, that naked men should defend themselves with their hands and teeth against armed men; and that so many persons should be buried under their enemies' arrows? Yet does there appear some probability in the thing, by reason it is not fought for the sake of the figure; but the hyperbola seems to arise out of the subject itself. Id.

Of the like kind is that passage of a comic poet, mentioned by Longinus: "He had lands in the country no larger than a Lacedaemonian epistle."

There are certain manners of tempering the harshness of hyperbolas, and giving them an air of probability. Virgil says, that to see the fleets of Antony and Augustus at the battle of Actium, one would have taken them for the Cyclades floating on the water: and Florus, speaking of the expedition wherewith the Romans built a number of vessels in the first Punic war, says, "It seemed not that the ships were built by workmen, but that the trees were transformed into ships by the gods." They do not say, that the ships were floating islands; nor that the trees were metamorphosed into ships; but only that one might have taken them to be so. This precaution serves as a kind of passport to the hyperbola, if we may be allowed the phrase, and makes it go down even in prose; for what is excused before it is said, is always heard favourably, how incredible fier the better. Bouhours. The excess in this trope is called auxesis; as when we say of any thing that is very high, "It reaches to the skies: the defect or contrary extreme is termed mutiss: as when we say of a very lean person, he is nothing but skin and bones, or a mere skeleton.

HYPERBOLIC, or HYPERBOLICAL, something relating either to an hyperbola, or an hyperbola.

HYPERBOLIC CONOID. See CONOID.

HYPERBOLIC CYLINDROID, is a solid figure, whose generation is given by Sir Christopher Wren, in the Philosophical Transactions.

Two opposite hyperbolas being joined by the transverse axis, and through the centre, a right line being drawn at right angles to that axis; and above that, as an axis, the hyperbolas being supposed to revolve; by such revolution, a body will be generated, which is called the hyperbolic cyclindroid, whose bases, and all sections parallel to them, will be circles. In a subsequent trans mutation, the same author applies the new figure to the grinding of hyperbolical glasses; affirming, that they must be formed this way, or not at all. Phil. Trans. vol. iv. p. 561.

HYPERBOLIC LOG of a curve, is that which has an asymptote, or tangent at an infinite distance.

Sir Isaac Newton reduces all curves, both of the first and of the higher kinds, into those with hyperbolic legs, and those with parabolic ones; that is, such as have asymptotes, and such as have not, or such as have tangents at an infinite distance, and such as have not. See CURVE.

HYPERBOLIC LINE is used by some authors for what we call the hyperbola itself.

In this sense the plane surface, terminated by the curve line, is called the hyperbola; and the curve line that terminates it, the hyperbolic line.

HYPERBOLIC LOGARITHMS, or NAPIERIAN LOGARITHMS, are a series of numbers, particularly useful in the determination and computation of fluents, arising from various problems in the higher branches of the mathematics; at the same time they have the property of common logarithms in facilitating many arithmetical operations, such as multiplication, division, extraction of roots, &c. &c.

These numbers are called hyperbolic logarithms, because they express the areas or spaces contained between the asymptote and curve of the hyperbola; those areas being limited by ordinates parallel to the other asymptote: the ordinates themselves decreasing in a geometrical progression. But this does not appear to be a proper method of denoting them, as such areas may be made to denote any system of logarithms whatever: for which reason they are now generally termed Napierian logarithms; from the name of their illustrious inventor, John Napier, baron of Merchiston, in Scotland. (See LOGARITHMS.) As we shall, under the article LOGARITHMS, enter at some length on the history of the invention, and the successive improvements of these very useful numbers, it will only be necessary, under the present article, to attend to the particular system which is the subject of our immediate consideration; by showing, in what way, it happened, that Napier fell upon this system, exclusively of all others: so that it is inferior to that of the common logarithms, for arithmetical and trigonometrical operations; 3dly, that these numbers necerelis arise in the determination and computation of fluents; 4thly, we shall shew their application to the problems before mentioned; and lastly, present the reader with the most extensive table of hyperbolic logarithms that has yet been published; being for every number from 1 to 10,000, and each true to the eighth place of decimals.

Napier, in the construction of his logarithms, did not adapt them to the series of natural numbers 1, 2, 3, 4, 5, 6, &c. as it was not his intention to extend them to arithmetical operations in general; but he confined his labours to that circumference which first suggested to him the necessity of the invention; and therefore he adapted his logarithms to the approximate numbers, which express the natural lines of every minute in the quadrant.

The fame refinement was purged through his method of constructing the logarithms. As the lines of the lines, of all arcs, are parts of the radius, or sine of the quadrant; he conceived the line of the radius to be described or run over by a point moving along it, in such a manner, that in equal portions of time it generated or cut off parts in a decreasing geometrical progression; leaving the several remainders, or lines, in geometrical progression also; while another point in an indefinitely line, described equal parts of it in the same equal portions of time; so that the respective sums of these, or the whole lines generated, were always the arithmetical or logarithms of these lines.

Thus a = the given radius on which all the lines are to be taken, and A, 1, 2, &c. the indefinite

\[ A = \frac{1}{2} \frac{2}{3} \frac{3}{4} \frac{4}{5} \frac{5}{6} \cdots \]

\[ a = \frac{1}{2} \frac{2}{3} \frac{3}{4} \frac{4}{5} \frac{5}{6} \cdots \]

plane containing the logarithms; these lines being both generated by the motion of points, beginning at A and a. Now at the end of the 1st, 2d, 3d, &c. moments or equal portions of time, the moving points being found at the places marked 1, 2, 3, &c. then will a, \( a = 1, 2, 3, \cdots \) &c. be the series of natural lines; and A o, or (o), A 1, A 2, A 3, &c. will be their logarithms, supposing the point which generates
HYPERBOLIC LOGARITHMS.

Let $a = 1 + p$, and $\log a = \log 1 + \log (1 + p)$, where $\log 1 = 0$.

The logarithm of a number is the exponent of that power of some other number, which is equal to the number itself; hence, if $r = a$, then will $x$ represent the logarithm of $a$; and $r$ will be the radix of the system, which is obvious by the above definition. If we take $r = 10$, it will be the common logarithmic system; and if $r$ be taken as $2.7182818$, it gives the hyperbolic logarithmic; and the reason for assigning to $r$ the above value will be evident from the following investigation. Since $r = a$, we must, in order to find the logarithm of $a$, obtain an expression for $x$, in the above equation in terms of $r$ and $a$; which may be effected thus:

Let $a = 1 + p$, and $\log a = \log 1 + \log (1 + p)$, we deduce

$$r = (1 + p)^x = 1 + \left( p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right) + \frac{1}{2} \left( p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right)^2 + \frac{1}{2} \left( p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right)^3 + \frac{1}{2} \left( p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right)^4 + \&c.;$$

and by making $p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. = t$, we shall have

$$1 + x = \frac{1}{2} x^2 + \frac{1}{2} x^3 + \frac{1}{2} x^4 + \frac{1}{2} x^5 + \&c.;$$

$$t = x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \&c.;$$

and

$$t = x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \&c.;$$

or

$$t = x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = x = \frac{1}{x} + \&c.;$

or

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = \frac{1}{x} + \&c.;$

or

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = \frac{1}{x} + \&c.;$

or

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = \frac{1}{x} + \&c.;$

or

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = \frac{1}{x} + \&c.;$

or

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = \frac{1}{x} + \&c.;$

or

$$x = \frac{1}{x} + \&c.;$$

and

$$x = \frac{1}{x} + \&c.;$$

which let be put equal to $q$; then by reverting the series, $x = \frac{1}{x} + \&c.;$
HYPERBOLIC LOGARITHMS.

But this last series is the same as that expressing the hyp. log of 
\( \frac{1}{1 + x} \), therefore the fluent of 
\( \frac{x}{1 + x} \) is the hyp. log. of 
\( 1 + x \). And the same rule is general for every quantity, of 
which the numerator is the fraction, or any multiple of the 
fluxion of the denominator; these being all reducible to the 
same form. (See Fluxions and Fluent.) Thus we have 

the fluent of 
\[ \frac{x}{1 + a} \] 
\( = \) hyp. log. of \( (x + a) \)

the fluent of 
\[ \frac{2a x}{a^2 - x^2} \] 
\( = \) hyp. log. of \( (\frac{x}{a} + a) \)

the fluent of 
\[ \frac{a^2 + x^2}{\sqrt{a^2 + x^2} + 2ax} \] 
\( = \) hyp. log. of \( (\frac{x}{a} + \sqrt{a^2 + 2ax}) \)

Thefe are only a few of the cafs in which hyperbolic 
logarithms are applied to the computation of fluents; and 
for the application of which to practice, the following table 
will be found very ufeful: it will need little or no explanation, 
being the fame in form as the common tables of 
logarithms; and all that is necessary to be observed is, that as the 
index of the logarithm is not repeated in every column, a 
small dash (—) is placed over the firit figure of the decimal, 
when any change takes place in the index. Thus, for 
example, the hyp. log. of 1097 is 7.00033446, the small dash 
indicating, that the index in that place changes from 6 to 7. 
If the hyperbolic logarithm of a fraction be required, we have 
only to subtract the log. of the denominator from that of 
the numerator for the log. fought: thus, the hyp. log. of 
\( \frac{\text{119}}{\text{1172}} \) = 4.77912349 — 7.06646697 = — 2.28734348; the 
whole of which expression is negative, whereas in the common 
system, the decimal part always retains a positive value, 
and the index only becomes negative; and this is again 
one of the inconveniences attending the hyperbolic system. 
When the natural number corresponding to any given hyp. log. 
is required, whether the given log. be positive or nega-
tive, it is always best to add to the given log. the log. of 
such a power of 10 as will bring it as near the end of the 
tables as possible, and then having found the natural number 
the same as in the common tables; divide the result by 
the same power of 10 for the natural number fought: the reason 
for which is, that the differences are too variable in the 
begiming of the table to be of any assistance in deducing the 
proportional parts. Suppose, for example, the given hyperbolic 
logarithm was — 3.28734348, and it was required to 
find the corresponding natural number. Now the hyp. log. 
of 10 = 2.30258509, multiply this by 5, we have 10^5 = 
11.51292545, which being added to the given log. we have 
— 3.28734348 + 11.51292545 = 8.22558197. Again, 

\begin{align*} 
\text{Nat. number} & = 8.22558197 \\
\text{Difference} & = 30781 \div 1 \div 7888 ; \div 2 \\
\end{align*} 

hence \( \frac{3735.2}{100000} \) is the natural number required.

And in this manner may the natural number answering to 
any given hyp. log. not in the table, be reduced to another 
within the limits of the table, by adding or subtracting from 
it such powers of 10 as are sufficient for that purpose; 
oberving always to repeat the reverse operation after the number 
is obtained. And by a similar method, the hyp. log. 
of any number not found in the table may be reduced to 
another, that is, by either multiplying or dividing it by such 
powers of 10 as may be necessary for that purpose; only 
remembering to subtract or add to the logarithm thus found 
the logarithm of the same power of 10, as that by which 
the given number was multiplied or divided. This will be 
more evident from the following examples:

**Exam. 1.** — Find the hyperbolic logarithm of 7854.

First, 7854 = 7854 \( \div 10000 \); and, therefore, the hyp. log. of 

7854 = hyp. log. 7854 \( - \) hyp. log. 10^4 \( = - \) 8.96877824 — 4 \( \times \) 2.30258509 = — 0.24156212, the logarithm fought.

**Exam. 2.** — Find the hyperbolic logarithm of 7854.

Here 7854 = 7854 \( \div 100 \); and, therefore, the hyp. log. of 

7854 = hyp. log. 7854 \( - \) hyp. log. 10^4 \( = - \) 8.96877824 — 2 \( \times \) 2.30258509 = 4.36468866, the log. required.

The following table of hyperbolic logarithms has been 
computed by Mr Peter Barlow, of the Royal Military 
Academy, Woolwich; and it is presumed that it will be 
considered as an acquisition to mathematicians: it forms only 
a small portion of an extensive set of mathematical tables 
calculated by the same gentleman; most of which are entirely 
new, but the flow demand that such works experience 
will, it is feared, prevent the appearance of this useful 
performance.

</tr>
</tbody>
</table>

**Notes:**
- The table continues with similar entries for each row.
- Each row represents a different value of the hyperbolic logarithm, with the values increasing sequentially.
- The table is designed to provide accurate logarithmic values for various calculations.

... (Continued with more rows)
HYPERBOLIC MIRRORS. See Mirror.

HYPERBOLIC SPACE, in the Higher Geometry, the area or space contained between the curve of the hyperbola, the asymptote, and the ordinates.

HYPERBOLICUM ACTUM, a solid made by the revolution of the infinite area of the space contained between the curve of the hyperbola and its asymptote. This produces a solid infinitely long, and yet is demonstrated to be equal to a finite solid or body. See Logarithmic Curve.

HYPERBOLOIDAL FIGURES are such curves as approach, in their properties, to the nature of the hyperbola; called also hyperboloids.

HYPERBOLOIDS are hyperboloids of the higher kind, whose nature is expressed by this equation, \( a y^2 + b x^2 + x^2 = c^2 \). See HYPERBOLA.

HYPERBOLOID denotes also the hyperbolic solid. See HYPERBOLIC.

HYPERBOREAN, \( \text{Hyperborea}, \) in the Ancient Geography. The ancients denominated those people and places Hyperborean, which were to the northward of the Scythians. They had but little acquaintance with these Hyperborean regions; and all they tell us of them is very precarious, and much of it false.

Diodorus Siculus says, the Hyperboreans were thus called because they dwelt beyond the wind Boreas; \( \text{Hyperborea} \) signifying above or beyond; and \( \text{Boreas} \), the north wind. This etymology is very natural and plausible, notwithstanding all that Rudbecks has said against it, who would have the word to be generally Gothic, and to signify nobility.

Herodotus doubts whether or not there were any such thing as Hyperborean nations: Strabo, who professed that he believed there were, does not take Hyperborean to signify beyond Boreas, or the north, as Herodotus understood it; the preposition \( \text{Hyperborea} \), in this case, he supposes only to help in forming a superlative: so that hyperborean, on his principle, means no more than \( \text{most northern} \); by which it appears the ancients scarcely knew themselves what the name meant by it. Strabo affirms for their habitation the country in the vicinity of the Enixe sea. Callimachus the poet places them near the Alps Meotides. Piny and Pomponius Mela place them behind the Riphean mountains, towards the icy sea. Virgil and Catullus are of the same opinion. According to Mela, Piny, and others, they inhabited a country in which they had a day and night of six months each. Moil of our modern geographers, as Hoffman, Cellarius, &c. have placed the Hyperboreans in the northern part of the European continent, among the Siberians and Samoedas; according to them the Hyperboreans of the ancients were those, in general, who lived farthest to the north. The Hyperboreans of our days are those Russians who inhabit between the Volga and the White sea. According to Clavius, the name Celtics was synonymous with that of Hyperboreans. These people, it is said, were accustomed to send the first productions of their fruits to Delos, to be consecrated to Apollo, whom they principally honoured.

HYPERCALECTIC, \( \text{Hypercalectic} \), \( \text{Hypercaldctic} \), composed of \( \text{hyper} \), over, beyond; and \( \text{alphae} \), I put to the number, \( \text{alpha} \); so that hypercalectic denotes as much as \( \text{hyperalted} \), in the Greek and Latin Poetry, is applied to verbs which have one or two syllables too much; or beyond the regular measure. See VERSE.

The Greek and Latin verbs are distinguished, with respect to their measure, into four kinds: \( \text{anticalectic} \) verbs, where nothing is wanting at the end; \( \text{catelectic} \), which want one syllable at the end; \( \text{brachycalectic} \), which want a whole foot at the end; and, lastly, \( \text{hypercaldtic} \), which have one or two syllables too many. These last are also called \( \text{hypermeters} \).

HYPERCATHARSIS, in Medicine, from the Greek \( \text{hypercatharos} \), \( \text{hyper} \), above; \( \text{catharos} \), clean, or \( \text{cleaning} \); or \( \text{purging} \) induced by medicine. Hypercatharsis is said to take place, when the frequency of loose stools, after any cathartic has been administered, continues great, after the operation of the cathartic might have been expected to cease; or when the purging operation is very fevere, being accompanied with a great discharge of serous or mucous fluids from the bowels, or with bloody evacuations. Such extreme purgation is most commonly occasioned by cathartics of a drastic nature; but we have seen it produced, in certain conditions of the constitution, by those of a milder quality, such as the crysals of tartar.

In old and debilitated habits, violent purgatives should be employed with great caution, and only when more violent ones appear to be altogether inadequate to accomplish the object in view; since a hypercatharsis, induced in such habits, may occasion a sudden depredation of the powers of life as may be irrecoverable. The ancients, from the paney of their catalogue of purgative drugs, were compelled to administer the white helibbers, where an active cathartic was required; and it would appear, from the aphorisms of Hippocrates, that convulsions and death occasionally followed the hypercatharsis, which that acid medicine produced.

The most effectual remedy for allaying the inordinate action and irritation in the bowels, in a hypercatharsis, is opium, under any form. If the strength is already considerably reduced, it may be combined with cordial and stimulant medicines, wine, and light but cordial nutriment. The absorbent and astringent substances may be advantageously united with the opiates, but are ineficacious alone; such are chalas, gum kino, the extract of log-wood, and especially the extract of catechu, which, when joined with aromatics and opium, as in the confertic catechu of the Edinburgh Pharmacopoeia, is a very effectual fouter of executive irritation in the alimentary canal. As the irritation, thus excited, is often chiefly seated in the large intestines, the opiates may be frequently administered in m.ulaenae or starch glisters with great and speedy benefit.

HYPERCHIRIA, in Mythology, a title of June, under which the was worshipped in Lucania.

HYPERCRISIS, in Medicine, a term used by Galen and other ancient writers to denote any inordinate critical excration, or \( \text{super-crisis} \), as it were. (See CATARAX.) Thus when a fever terminates by a profuse sweating or diarrhoea, the discharge being greater than the strength of the patient is able to bear, a hypercrisis was said to take place. See Galen, cap. 3. propnoll.

HYPERCRITIC, composed of \( \text{hyper} \), \( \text{critica} \), a judgment, or \( \text{critica} \), of \( \text{hyper} \), \( \text{above} \), \( \text{judex} \), of \( \text{hyper} \), \( \text{judge} \); an over-rigid cenfor, or critic; one who will let nothing pass, but animadverts fiercely on the slightest fault.

HYPER-DIEUXEUXIS, in Music, the disjunction of the two tetrachords, separated by the interval of an octave, as the tetrachord hypertun and hyperbolon.

HYPER-DORI N, a mode so called in Greek music, and sometimes denominated Mixo-Lydan; the fundamental or key-note of which was a fourth above the Dorian. See Mode.

The invention of the hyperdorian mode is ascribed to Pythocles.

HYPERDULIA, \( \text{hyperduliac} \), composed of \( \text{hyper} \), \( \text{above} \), and \( \text{dulia} \), worship, in the Roman Theology, is the worship rendered to the Holy Virgin.

The worship offered to saints is called \( \text{dulia} \); and that to
the Mother of God, hyperalia; as being superior to the former.

HYPERICOIDES, in Botany. See ASCYRUM.

Gen. Ch. Cal. Perianth inferior, in five deep, nearly ovate, concave, permanent segments. Cor. Petals five, oblong-ovate, obtuse, spreading, obliquely twisted according to the sun's motion. Stam. Filaments numerous, capillary, united at the base into three or five bundles; anthers small, roundish. Phy. German superior, roundish; styles three or five, sometimes one or two, simple, dilatant, the length of the filaments; stigmas simple. Peric. Capsule roundish, the number of its cells agreeing with that of the stigles. Seeds numerous, oblong, affixed to the central column.

Eff. Ch. Calyx in five deep segments, inferior. Petals five. Filaments numerous, united by the base into three or five sets. Capsule with many seeds.

A copious and handsome genus, chiefly European, American, or Chinesee, rarely tropical. Willdow has 89 species; 11 are now known as belonging to the British Flora. The stems are either strubby or herbaceous, usually angular. Root perennial. Leaves simple, opposite, sessile, entire. Whole herbage generally smooth, with glandular pellucid dots, and an aromatic scent, rarely downy. Flowers terminal, cymose, yellow and brilliant. Calyx often fringed.

Common wild species are,

H. calycinum, Curt. Mag. t. 146. Engl. Bot. t. 2017, now known to be wild near Cork, in Ireland, is a frequent ornament to shruberies and parks, where its ample blossoms are very confusious.

Several strubby American species are cultivated with us for ornament, as the bicircum, remarkable for its strong fox or goat-like scent.

HYPERIDES, in Biography, an eminent Grecian orator, the son of Glanippus, was born at Athens, and studied under Plato and Iocrates. He cultivated the art of eloquence, became one of the most distinguated orators of his time, and acquired that sway in state affairs which popular oratorical talents never failed to obtain in ancient democracies. He was the steady and zealous opponent of Philip of Macedon, and his zeal cauised him to be made commander of a galley, in which capacity he gained much credit by his promptness and zeal in succouring the Byzantines. When Philip threatened an invasion of Euboea, Hyperides procured a tax to be levied for the equipment of 46 galleys, and fet the example by contributing one for himself and another for his son. In the time of Alexander he was ppossessed of the chief influence in Athens, and when that prince demanded galleys and officers from the Athenians he opposed the grant of either. His life was fully devoted to his country. He moved distingueded honours to Demotethes his great competitor in eloquence; but when this prince of orators was suspected of having taken a bribe from Harpalus, he was appointed to conduct the prosecution against him. Hyperides was himself accused of having acted contrary to the laws, by procuring a decree for granting citizenship to foreigners, and liberty to the slaves, whole families he cauised to be transported to the Pireaus, but he justified himself on the ground of flate necessity, and proved that it was not he who passed the decrees, but the alarm with which Athens was seizd, and the defeat of the Charones. Hyperides continued his opposition to the Macedonian power after the death of Alexander; and when Antipater sent deputies to Athens, who made a high eulogy upon their master as the worthy of men: I know, replied Hyperides, that he is a very worthy man, but we will have no maller however worthy he may be. The approach of Antipater obliged Hyperides and the other leading characters to quit Athens, and he had an interview with Demotethes, also a fugitive at Acina. Departeing thence, he was seeking for a safer place of refuge, when he was apprehended by Archias in the temple where he had taken sanctuary, and carried to Antipater at Cleone. He was put to the torture with the hope of obtaining from him some flate secrets: to prevent this he is said to have bit off part of his tongue; but another account relates that his tongue was cut out by the tyrant as a punishment due to his licene. His body was left unburried till some of his relations secretly committed it to the funeral pile, and brought his ashes to Athens. Quintilian characterizes the oratory of Hyperides as singularly sweet and acute, better adapted to little than to great causes. In the time of Plutius 52 of his orations were extant. Gen. Biog.

HYPERIDROSIS, the diaphation of a part by water.

HYPERINESIS, of ὑπερὶν and ὄνειρον, a word used by Hippocrates for any excessive evacuation, but most frequently in the same sense as hypercatharisis, an over-purging.

HYPER-Ionian, in Ancient Myth, one of the Greek modes, whose fundamental was one fourth above the Ionian. It is the 12th mode ascending in the scale.

HYPERIUS, Gerard Andrew, in Biography, was born at Ypres in Flanders, whence he took his surname, in the year 1511. He was sent to Paris to complete those studies which he had successfully commenced in the Flemish schools. He excelled on the law and medicine, by which he was executed with much diligence till the year 1525. During the vacations he travelled much in different countries, and after he had completed his studies at Paris he spent some time at Louvain, and then visited several other German universities. These visits into heretical countries not only perplexed him from being preferred in the church, but obliged him to seek the secrutiy of his peron in England, which at almost every period of his life has been more or less friendly to the rotaries of freedom. He lived four years in the house of Charles lord Montjoy, who settled on him a handsome stipend, which enabled him to apply himself to the pursuits of literature. During this period he embraced the opportunities offered him of visiting the universities of Cambridge and Oxford, but, alarmed at some proceedings of Henry VIII., he returned to the continent, settled at Marburg in 1542, and was appointed to the theological chair. The duties of this office he performed with great reputation 22 years. He died in the year 154, about the age of 53. He was author of numerous works, some of which were publishd by himself, and the reft were given to the world after his death. They confit of "Commentaries on the Scriptures;" "Theological Diflaffations;" "Controversial Tracts;" treaties in rhetoric, logic, arithmetic, geometriy, altronomy, optics, natural philosophy, &c. Hyperius, says his biographer, had
had a very clear head, and a very happy talent in conveying
instruction. He was meek and polite in conversation,
delighted in fancied convivial intercourse. In a word, he was
a man who poiseffed true wit and good sense, and who added
to those qualities a high degree of virtue and zeal. Bayle.

HYPER-LYDIAN, in Mufic, the most acute of the
15 Greek modes. Its fundamental was a fourth above the
Lydian.

HYPERMETER, composed of διαθ., χόρδ., and χορδο-,
monex, in the Ancient Poetry, the name with hypercatalectic.
HYPEROA, a word applied by authors to the upper
part, or palate of the mouth, and the basal cerebri. It
properly signifies any upper place.

HYPEROCHE of Dr. Bulley, in Mufic. (Mus. Dict.)
is "the difference between the enharmonic and chromatic
dieis," an interval, whose ratio is \( \frac{2097152}{2109375} = 5 \frac{2}{f} \),
which is the semi-comma maxime of Rameau, fee that article.
A doubt, however, remains with us, as Dr. B. has
quoted no author, only mentioning the ancient authors
generally, nor given the ratios, whether by the term "chromatic
dieis," he did not mean the ma of Holder, Chambers, &c.
in which case his hyperocbe would coincide with the
hyperoche of Henfling and others below.

HYPEROCHE of Dr. Calcutt. In purpling the additions
by Dr. Calcutt to the Overend MS. which we have so often quoted,
we met with an interval so named, whose
ratio is \( \frac{1667218}{16666569} = 5 \frac{2}{f} \), which is the
greater residual, fee that article.

HYPEROCHE of Henfling, Travers, Dr. Pepusch,
Overend, Dr. Calcutt (Musical Grammar, art. 23 r.), &c.
is an interval whose ratio is \( \frac{3072}{3125} \), or \( \frac{3}{2} \), its value in Fa-
rey's notation being \( 15 \frac{2}{f} + m \); its common logarithm
is .99257113968, the reciprocal of which is .74288,1032;
Euler's or binary logarithm is .024679, fuch being its
decimal value of the octave \( i \) : it is equal 1.57956 major
commas, and to 1.157524 schifmas. It is equal to the
sum of the following pairs of intervals, \( \text{viz.} \) a diatonic
and a medi-cus, a major comma, and a semi-comma major
of Lameau, a minor comma and a demi-comma maxime of Ra-
meau, a diez minime and a schifma, a prifma and five
schifmas, &c. It refults, as the difference between the follow-
ing pairs of intervals, \( \text{viz.} \) a femtore minor and an
enharmonic dieis, an enharmonic dieis and a major residual,
a femtore subminime and a minor comma, a major comma
and two enharmonic dieis, a chromatic dieis and a major
comma, two femtore minor and a femtore major, two minor
tones and three major femtore, three minor femtore and
a minor tone, &c. The following three intervals also com-
pose it by addition, \( \text{viz.} \) a schifmum, a minor residual and
a diatonic, a schifma, a medi-cus residual, and a major comma,
&c.

If three major thirds be turned upwards, and two minor
thirds and a fourth downwards, each true and without any
beats on an instrument having sufficient string, this interval
will refult; which, in the additions to the Overend MS. by
Dr. Calcutt, is designated by the Greek small \( p \) or \( \pi \).

HYPEROCHE of Ptolomy, is an interval whose ratio
is \( \frac{138}{129} \) or \( \frac{129}{343} \), or 6.8886 \( \frac{2}{f} \), and therefore not in
the diatonic scale: its common logarithm is .99662255935,
and its Euler's log = .01127275, and it is equal to
.6264543 major commas. It cannot, of course, be tuned
by any combinations of perfect concords, though it readily
may by calculating the Beats which it makes. See that
article.

HYPERO-PHARYNGEAL, in Anatomy, a name given
by M. Santorini to the pharynx-pharyngeal muscles.

HYPEROSTOSIS, from base upon, and ōs, a bone,
in Surgery, any hard indolent swelling upon a bone. See
EXOSTOSIS.

HYPER-OXYMURIATES. See the following arti-
cle.

HYPER-OXYMURIATIC ACID, in Chemistry. This
acid contains a greater proportion of oxygen than the oxy-
muriatic acid, and on that account has received its name. It may
be procured in combination with potash, in the following pro-
ces: if a quantity of potash, with six times its weight of
water, be put into one of the bottles of Woulfe's apparatus, and a
stream of oxymuriatic acid gas be passed through it till the
potash is saturated, a crystallised form of fine white scales
fall to the bottom; these are crystals of hyper-oxy-muriatic
of potash, being a compound of potash and hyper-oxy-muriatic
acid. This acid is chiefly known in its saline combination.
These are named hyper-oxy-muriates, and from the peculiarity of their chemical composition—the large quantity
of condensed oxygen existing in them, and retained by no
very strong attraction, their characters are extremely dif-
ferent. The principal are those, they afford very pure oxygen
when exposed to a red heat, detonating with great violence
with inflammable bodies, either on the application of heat,
or by mere percussion or trituration, and causing those
bodies to burn when sulphuric or nitric acid is added to the
mixture of the salt and the inflammable matter. Their taste
is cold and penetrating; they are generally soluble in water,
and crystallizable: the greater number of them are also sol-
uble in alcohol. They do not precipitate any of the metal-
ic salts; nor destroy the vegetable colours, but in small
quantities they heighten them. The hyper-oxy-muriatic acid
contains:

<table>
<thead>
<tr>
<th>Oxygen</th>
<th>65 parts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muriatic acid</td>
<td>35</td>
</tr>
</tbody>
</table>

The order of the affinities of the hyper-oxy-muriatic acid
is the following:

<table>
<thead>
<tr>
<th>Potañf</th>
<th>Lime</th>
</tr>
</thead>
<tbody>
<tr>
<td>Soda</td>
<td>Ammonia</td>
</tr>
<tr>
<td>Barytes</td>
<td>Magnesia</td>
</tr>
<tr>
<td>Stronties</td>
<td>Alumine</td>
</tr>
</tbody>
</table>

From the hyper-oxy-muriates of potash, oxygen-gas can be
obtained in the greatest purity; but the most astonishing
of its properties are those which it exhibits when mixed with
combustibles. All combustible substances are capable of
decomposing it, and in general the decomposition is attended
with violent detonations. When three parts of this salt
and one of sulphur are triturated in a mortar, the mixture
detonates violently: the same effect is produced when the
mixture is placed upon an anvil, and struck smartly with a
hammer. It sometimes detonates spontaneously without any
perceptible friction. Charcoal produces the same effect, though
not so violent. This property led Berthollet to propone it as a
substitute for nitre in the preparation of gunpowder. The
attempt was made in 1788, but as soon as the workmen
began to triturate the mixture of charcoal, sulphur, and the
hyper-oxy-muriate of potash, it exploded with violence, and
proved fatal to two of the experimenters. Phosphorus
detonates with this salt either by trituration or percussion, but

Vol. XVIII.
the quantities used should not be more than half a grain each, or there will be danger in the experiment. When this salt is triturated in a mortar with a little cotton cloth, small repeated exfoliations are heard similar to the crack of a whip, and if the cotton be dry and warm it sometimes takes fire. When nitric acid is poured upon a mixture of oxymuriate of potash and phosphorous, flakes of fire are emitted at intervals for a considerable time. The theory of these phenomena is this: the oxygen of the acid combines with the combustible, and at the same time lets go a quantity of caloric: and a trituration or concussion acts merely by bringing the particles which combine within the sphere of each other's attraction. The constituents of the oxymuriate of potash are:

58.5 Acid, 59.2 Potash, 2.5 Water.

It is prepared by dissolving one part of carbonate of potash in five parts of water, and fusing the potash with oxymuriatic acid gas. When the fusion is nearly completed the oxymuriate falls down in crystals. It is purified by solution in boiling water; as the water cools, the pure hyper-oxymuriate crystallizes. The crystals are to be dried between the folds of blotting paper. Hyper-oxymuriate of soda may be prepared by the same process as hyper-oxymuriate of potash; it crystallizes in cubes, and it produces a sensation of cold in the mouth. The other hyper-oxymuriates that have been examined are those of ammonia, magnesia, lime, barytes, and frontian. See Muriahi Acid, in which article an account of Dr. Davy's experiments on it, with a view to its decomposition, and the results will be given.

Hyper PHRYGIAN, in Ancient Myth, called by Euc-ild hyperminyoidyan, was the most acute of the thirteen modes of Arirloxmas.

Hypersarcoma, or Hypersarcomus, from ευς and σαρκα, flesh, a fleshly excrecence; fungous granulations; proud flesh.

Hyperthyron, formed of ευς, over, and ψαρκα, gate, in the Ancient Architecture, a sort of table used before the manner of a frieze, over the jambs of Doric doors and gates, and the lintels of windows. It lies immediately under the cornice; and is, by our workmen, usually called the king-piece.

Hypethre, two rows of pillars surrounding, and ten at each face of any temple, &c. with a peristyle within of six columns. See Hypethriosts.

HYPHASIS, or Huphasis, in Ancient Geography, a river of India, called anciently by the natives Hyppaia; now the Bega; which see.

HYPHEN, *c* in Grammar, an accent or character, which implies, that two words are to be joined, or connected into one compound word—As, male administration, &c.

Hyphens serve also to connect the syllables of such words as are divided by the end of the line.

HYPHIATRES, EHHIALTES, in Mythology, names given by the Greeks to certain rural divinities answering to the Incubi of the Romans.

Gen. Ch. Male, Cal. Perianth of one leaf, deeply divided into three, obovate, concave, smooth lobes incurved at the top. Cor. none. Stam. Filaments short, capillary, long, inserted, at the angles, above the germen; anthers roundish.

HYPH, or Hyp, in Botany, German empty, inflated, membranous, hexagonal, truncated at the top; style capillary, the length of the flammis; stigmas none.—Female, Col, Cor. and Stam, none.

Hyp, or Hyp, German roundish, with three funnels; style triangular; stigma three, acute. Petal. Capsule membranous, of one cell, and three valves. Seed solitary, ovate, streaked.

1. H. amplexicaulis. (Toniuna floristitis; Aubl. Guian. 837. t. 330.—Ericaulon amplexicaule; Roth. Surinam. t. 1. f. 1.)—An inhabitant of waters at Guiana and Cayenne, flowering and bearing fruit in February. Thistle puts forth many branching, scattered, erect or decumbent little stems, furnished with capillary radicles. Leaves alternate, smooth, narrow, lanceolate, acute, fringed longitudinally with reddish bristles, feathery, embracing the stem. Flowers capitellate, axillary, on solitary flowerstalks.

HYPNOTIC, *c* in Medicine, a remedy which promotes or induces sleep; called also soporific and opiate. See also Narcotics.

HYPNOTICUS SERPENS, the snake, in Zoology, the name of an East Indian species of serpent, called by the Ceylonese ninitpalga, a word importing the same feasts. It is of a deep blackish brown, variegated with spots of white, and is a very fatal kind in its poison, its bite always bringing on a fever which ends in death.

HYPNUM, in Botany, an ancient name for some kind of moss, formerly used in medicine. The word is supposed by Dillenius, who first adopted it for the particular genus to which it is now applied, to originate from ευς; sleep; and he justifies its application on the principle of fragrant substances, like these mossy, producing sleep. Dill. Mufc. 261. Lim. Gen. 564. Schreb. 762. Hedw. Fund. v. 2. 94. Sm. Fl. Brit. 1376. Juss. 11. Lamarck Illufir. t. 84. (Leukia; Schreb. 762. Hedw. Fund. v. 2. 93. t. 10. f. 62—65.)—Claws and order, Cryptogamia Mycit. Nat. Ord. Mycit.

Eff. Ch. Capsule ovate-oblong, from a lateral feathy sheath. Outer fringe of fifteen teeth, dilated at the base; inner a variously-toothed membrane; veil smooth.

This vail and beautiful genus differs from Bryum, (see that article), in no other essential character than the lateral, not terminal, situation of its female flowers. The habit, however, is widely different. Hypnum has usually a lax, spreading, repeatedly branched item, whence its English name of Feather-mosses, cloathing the ground to a wide extent, and being of larger dimensions than most others of this family. The species in the Flora Britannica are 77, and a few others have been found since that work came out. The Species Mufearum of Hedwig defines 83 Hypnum, besides 35 species of Leukia, or Leukia, a genus comprehended under Hypnum in Flor. Brit. Yet there, making together 118, form but an inadequate catalogue of the known species, and some of them are reducible to other genera, H. Smittii of Dickson and Hedwic being a Petroniani; and others belonging to Hookeria. The difference on which Hedwic founds the distinction between Hypnum and Leukia confilts in the inner fringe, the teeth of which in the latter are equal and uniform, usually 16 in number, while in the former there are 16 broad teeth, with single or double intermediate ones. This distinction, however, proves not only extremely difficult to define, but totally unnatural as to the species it brings together or separates, and by no means certain or constant in each. See Frickia of Mosses.

Hypnum is distributed into several sections.

H Y P

Of this H. palebellum, Engl. Bot. t. 2066, and ferioeum, t. 1445, the latter very common on walls, roofs, banks, and trees, may serve for examples.

2. Capsules erect. Shoots compressed, the leaves being disposed in two ranks.

The only two British species here are compostum, Engl. Bot. t. 1492, and trichorhizoides, t. 1493.

3. Capsules drooping or curved. Shoots compressed, the leaves in two ranks.

Such are denticulatum, t. 1260; creultanum, t. 1261; formulatum, t. 1262; and the common riparium, t. 2063. But burra no longer remains here, being now called Hookeria burra, (see Hookeria;) and there is much reason to believe the beautiful undulatum ought also to make one of a new genus, marked by its furrowed capsule.

A handsome tribe, see Splendens, Engl. Bot. t. 1424; prolyherum, t. 1491. Curt. Lond. fasc. t. 72, very common in woods, but rarely in fruit; and prolongum, t. 2035, also very frequent.

Leaves imbricated every way.

A rather numerous faction, in which we find Aloeceurus, Engl. Bot. t. 1182, a native of shady moist rocks; serpens, t. 1237, very common, known by its white stem; /china, t. 1301; and the beautiful though vulgar parum, t. 1399.

6. Capsules drooping or curved. Leaves isochrorous.

The sharp prominent leaves, projecting on all sides of the branches, give the peculiar character of this very distinct faction, as in splendens, t. 1448; fictatum, t. 1648; fictatum, t. 1304; and the great well-known tripentum, t. 1612.

7. Capsules drooping or curved. Leaves culled.

In this elegant faction are rugosa, t. 2250; forrificio, t. 1093, the figure done from too young a specimen, but otherwise correct; cupressiformes, t. 1800; mollissimum, t. 1327, and a near relation of the last, though much finer, the true H. Christi cf. coffeacolo, t. 2108, recently discovered in Scotland by Mr. G. Don.

HYPO, τηπολος, a Greek particle retained in the composition of diverse words borrowed from that language; literally denoting under, beneath.—In which sense it fluids opposed to τηπολος, αντιτροπος, and αντιτροπος, I. e., in Subjection, in Rhetoric, a figure, so called, when several things are mentioned, that seem to make for the contrary side, and each of them refuted in order. This figure, when complete, consists of three parts; a proposition, an enumeration of particulars with their answer, and a conclusion. Thus Cicero, upon his return from banishment, vindicates his conduct in withdrawing to quietly and not opposing the faction that ejected him. Pro. Dom. cap. 35.

HYPOPLETHARYSIS, τηπολος, composed of ηπολος, under, and τροπος, I. e., a change, in Medicine, a too faint or feeble purgation.

HYPOCAUSTUM, τηπολος, formed of the proposition τηπολος, under, and the verb τροπος, I. e., burned, among the Greeks and Romans, was a subterraneous place, wherein was a furnace that served to heat the bath.—Vitruvius calls it caldarium.

The ancients had properly two forts of hypocausts; the one called by Cicero panorarium, and by others ignacaeum, or incalidum; which was a large sweating bath, in which were three brazen vessels called caldarium, tepidarium, and frigidarium, according to the water contained therein.

The other hypocaustum was a fort of furna or oven, to heat their winter parlours, or centauroo hybline.

The latter hypocaustum was called alveus and forius; and the man that tended the fire, forunator. See BATHS.

The remains of a Roman hypocaustum, or sweating-room, were discovered under ground at Lincoln, in 1739. We have an account of these remains in the Phil. Trans. No 401. p. 297. See Abr. vol. ii. p. 455.

HYPOCAUSTUM, among the moderns is that part or place where the fire is kept that warms the bade or bath-house.

Gen. Ch. Common Calyx roundish, imbricated, flowering at the base; the scales lanceolate, acute. Cor. compound, uniform, imbricated, the florets hermaphrodite, equal, numerous, each with one ligulate, linear, abrupt, five-toothed petal. Stam. Filaments five, capillary, very short; anthers united into a cylindrical tube. Pijl. Germin ovate; style thread-shaped, the length of the ifames; stigmas two, reflexed. Peric. none, except the closed calyx, assuming a globose pointed shape. Seeds foliary, oblong. Down feathery, silky. Recept. clothed with linear-lanceolate scales, the length of the seed.

Obs. Haller, Reichard, and others have remarked, that in H. glabra the seeds of the circumference have visible down. See Fl. Brit. 891.

Five species of Hypocheris are defined by Wilklow, one Limnean ones being removed to Seriola. Three are natives of England; and the maculata, Engl. Bot. t. 2575, found in chalky open pastures, but rarely; glabra, t. 575. Curt. Lond. fasc. 3. 53. a native of gravelly fields, sometimes found among turnips in Norfolk, in which case it is very luxuriant; and radicans, Curt. Lond. fasc. 3. 57. Engl. Bot. t. 571, a very common weed.

The third is perennial, with a nodulous, rather large, yellow flower, and toothed, roundish leaves tinted with black. The second is annual, smooth, with several small, pale, yellow flowers, expanding in the morning only. The third is perennial, with rough runcinate leaves, a smooth branching stem, and large flowers of a full yellow.

The other two species in Wilklow are,

1. H. helvetica, Jacq. Ic. Rar. t. 165, a large and handsome plant, confounded by Linneus with his maculata, from which its narrower, lanceolate, unspotted leaves, perfectly simple stem swelling upward, and very large flower distinguish it. This species, found on the Alps, is delineated by Haller, Allioni, and Villars, being a favourite with alpine botanists.

2. H. minima, Desfont. Atlant. v. 2. 298. (H. hylida; Roth. Catal. v. 1. 100.) Native of Bavary, resembling H. glabra, but scarcely half its size, with roughish leaves and a brilify calyx.

HYPOCHEOMENOS, a person afflicted with a cata- ract, or opacity of the crystalline lens of the eye. The term is derived from τηπολος, to suffuse.

HYPOCHONDRIA, in Anatomy, from τηπολος, under, and χονδρα, cartilages, those parts of the cavity of the abdomen which are covered by the inferior ribs and their cartilages.
HYPOCHONDRIASIS.

HYPOCHONDRIASIS, in Medicine, a disorder principally characterized by an anxious and apprehensive state of mind in respect to the patient’s health, and by an imaginary suffering of many morbid affections, together with a deranged state of the digestive organs.

This complaint has been known from ancient times, and has received a great variety of appellations, many of which have been derived from hypothetical views of its nature. The term hypochondriasis or hypochondria, is taken from hypochondrium, organ, which signifies literally under the cartilages, and is the name given by anatomists to the upper and lateral regions of the belly which lie under the cartilages of the false ribs. This appellation was probably given to the disease in question, in consequence of the general uneasy sensations which are experienced by hypochondriacs in these parts of the body, especially on the left side; as well as from the opinion of physicians, that the seat of these sensations, and of the disease itself, is always in some of the organs which lie in the hypochondrium, and which are: the stomach and spleen on the left side, and the liver on the right. The Arabian denominated the disease Mirachia, the word Mirack, in their language, signifying the abdomen or belly. The opinion, which was for a long time prevalent, that the spleen was principally the seat of the disorder, gave occasion to the use of the name of that viscous to denote the malady. And another hypothesis, that the disordered state of the mind was excited by vapours arising from a collection of fetid and offensive matter accumulated in the spleen and false passages, gave rise to the denomination of vapours, by which the malady has also been designated. The French called hypochondriacal persons, maladies imaginaires, from the various imaginary evils of which they complain. The term hyp and hypo, familiarly used in this country, are obviously contractions of the Greek name.

It would be impossible to give a regular history of all the symptoms of a disease, which is varying and irregular in its phenomena, and includes, in different instances, almost all the painful sensations and signs of disordered functions, that are witnessed in the various complaints incident to the human frame. We must content ourselves, therefore, with delineating the peculiar features of the disorder, and enumerating the most remarkable circumstances that have been observed to accompany it. We might say, in a few words, that, after a series of symptoms, evincing a deranged state of the bodily health in general, but especially of the organs of digestion, which have continued for an indefinite length of time, a state of mind gradually steals itself, which is distinguished by the following circumstances: languor, lassitude, or want of resolution and activity with respect to all undertakings; a lowering of spirits, sadness, and timidity; and with respect to all future events, a dread and apprehension of the worst, or most unhappy occurrences, often upon the slightest grounds. But this apprehension is particularly directed to the state of the patient’s health; he attends minutely to every change of sensation, and from every unusual feeling, though of the slightest kind, anticipates great danger, and even death itself. He supposes himself, at different times, as these sensations vary, afflicted with every disorder in succession that he has either seen, heard, or read of; and, in respect to all these feelings and apprehensions, he commonly entertains the most obstinate persuasion and belief, and is even disoblige to any person, who shall intimate that he looks well. He is fond of complaining, and tireless in defending his maladies: never satisfied with medicines, yet constantly anxious to fly from remedy to remedy; and equally detestful of medical counsel, yet fain dissatisfied with every physician. As the disease advances, he is afflicted with most unaccountable sensations and affections, which can be only referred to his imagination.

Such, in brief, is the character of hypochondrias. This state of mind, however, as we have just stated, is ushered in and accompanied by various symptoms of corporeal disease, which are principally referable to a disordered condition of the digestive organs, with which other organs also suffer in sympathy. Thus the person is troubled for a considerable time with flatulency, and a f时常 of heat and pain along the course of the aërophagus and the pit of the stomach, called heart-burn, sometimes attended with acidity and sometimes with a feeling of oiliness and regularity, especially when elevation takes place. The air, which is evolved in the stomach, produces great dilatation of that organ, and this dilatation is always accompanied with an uneasy feeling and sense of anxiety; this wind afterwards descends into the bowels, producing croaking and rumbling noises, called borboris, and exciting prickings of the mouth, flatus, thumpings, and pulsations in the belly,” as Maundeville describes them, which occasion fleshy convulsive motions of the abdominal muscles. The appetite is frequently bad, but in some cases craving, and is generally irregular in the beginning, as well as the alvine discharge. As the disorder advances the patient is generally very colicky, discharging black, hardened excrement, with much pain and straining. At this time the bowels are moved with difficulty, and require strong cathartics to produce any effect: hæmorrhoids or piles, especially internal ones, accompanied with great pain, and not unfrequently with bleeding, are liable to occur. Sometimes a diarrhœa suddenly comes on; but so far from giving relief, it rather exhausts the strength of the patient, and leaves him low and dejected.

While these symptoms of indigestion prevail, others, which appear to be the direct or indirect consequence of them, are often very troublesome. There is often a weight, oppression, or tightness felt about the precordia, with palpitations of the heart: the face is frequently flushed, and flying heats are felt even over the whole body; the head often aches, and the eyes are dim. The urine is various: it is often of a yellow, or yellowish white appearance, which always announces a great weakness and disorder in the chylipode vasa; at other times a pale and limpid urine is passed in large quantities, especially after any agitation of mind, or hurry of spirits. Cold sweats, which alternate with flushes of heat, fainting, giddiness, deafness, ringing in the ears, and disturbed and unrefreshing sleeps, from which the patient wakes in fright, are common symptoms in the advanced stages of the disorder. The whole nervous system is deranged. The patient generally feels a much more oppressive sensation of weakness and fatigue than is natural, considering the muscular strength which he is capable of exerting. Slight symptoms of debility, which in another person would hardly produce any disagreeable effect, for instance, sudden dilatation of the stomach, slight palpitation, or colic, instantly occasion all the alarming feelings of fear and apprehension: these are accompanied with a degree of anxiety which cannot be described.

But the hypochondriac has many painful feelings in parts where no disease apparently exists, and many diseased perceptions which command his belief, and greatly add to the sum of his misery. A number of those distressing feelings are often external pains, felt immediately under the skin, and in parts which, when examined, appear to be in a found state.
HYPOCHONDRIASIS.

flate. Sometimes the pain is felt in the middle of one or two of the ribs; sometimes in the middle of the leg, thigh, or arm; sometimes in the back, and in various parts of the scalp. That these painful feelings are generally transmitted from impressions in the flomach and bowels, appears from this; that they are most frequent, when the patient is troubled with indigestion, flatulency, colicnefs, or colic: what is very remarkable, the external pain is often increased by pressure. Dr. Crichton mentions the cafe of a gentleman who suffered exceedingly from these falle pains. If the finger was pressed upon the painful part, the imaginary excited fpirits in the organs of respiration, and the fneezings, often occasioned fo much agony, as to make him fcreem aloud; after the pressure was removed, the pain ceased. These pains were continually shifting their place, and often wandered over half the patient's body in the course of the day. Dr. Whytt, after enumerating many facts, concludes, "that fadnifhes, tremors, palpitations of the heart, convulptive motions, and great fearnefses, may he often owing more to the internal state of the firft paffages, than to any fault either in the brain or heart." He farther remarks, in regard to himself, "When my fmomach and bowels have been out of order, and affected with an uneasy fenfation from wind, I have not only been liable to general debility and flatnefs of fpirits, but the unexpted deprefsions of the heart, and any fuch trifling unfeen accident, has instantly occasioned an old fcnfation about my heart, extending itself from thence to my head and arms, and, in a lefter degree, to the inferior parts of my body. At other times, when my ftomach is in a firmer flate, I have no fuch feelings, or at leat in a very fmall degree, from caufes which might be thought more apt to produce them." Whytt on Nervous Disorders, chap. iii.

When the disagreeable feelings, dejection of fpirits, and unremittitng anxious attention to their health, and to every new fcnfation, have continued for an indefinite time, which is longer or shorter, according to a variety of circumstances, difeafed perceptions fuddently affume, which claim the belief of hypochondriacs. It would be vain to attempt an enumeration of all the extravagant ideas which enter into the minds of fuch people, since they are infinitely various. Some think that their extremities and posteriors are made of glass; others that their legs are as soft as wine; some think they have no heart, others that they have no foul; others fancy that they are dead, and others that they are changed to mummies, &c. In others, the disorder verges upon melancholy, and ideal pains of poverty, perfecution of enemies, secret vengeance, and calamity, haunt them perpetually: but in this cafe, the difeafe may be confidered as having pafed the limits of hypochondriasis, and put on the character of infanity. When hypochondriacal affections arise from difeafed vifcera, the erroneous ideas, which present themselves to the mind of the patient, generally concern their own frame. It is not very easy to trace these erroneous perceptions to the original painful, yet obscure fcnfations in the body, to which they owe their existence. It is only, indeed, by a long continuance of thefe fcnfations, that they become associated with the strange notions of hypochondriacism. "Nothing can be more interesting," Dr. Crichton remarks, "to a physician who is endowed with only a moderate share of the spirit of obfervation, than the progress of this complaint in a number of patients, especially in regard to its effects on the mind. They always struggle more or lefs in the beginning, with the lownefs and dejection which affect them; and it is not until many a fever conftant has taken place between their natural good fente, and the involuntary fuggen- tions which arise from the obscure and painful feelings of their difeafed nerves, that a ffirm belief in the reality of fuch thoughts gains a full conquest over their judgment. A ffirm belief in any perception never takes place until it has acquired a certain degree of force; and as all fcnfations which arise from the vifcera of the abdomen are naturally obscure, we fee the reafon why thefe muft continue for a great length of time, or be often repeated before they can draw a perfon's attention from the ordinary fcnfations of external objects, which are clear and distinct, and before they acquire such a degree of vividnefs as to destroy the operations of reafon." An Inquiry into the Nature and Origin of Mental Dercarations, vol. i. p. 227.

Dr. Crichton thus attempts to explain the fact, that the fource of the mental illusion generally lies in the abdomen. "Most of the objects which surround us have been examined by feveral of our fentences; we have compared the various fcnfations they have yielded, and ftefe, therefore, become associated in our minds; fo that if any external body, thus examined, be again prefented to only one of our fentences, the idea of all its various qualities is recalled, and we neccffarily believe in their reality. The fources of almost all our perceptions, while we are in health, lie in external objects; for the nerves of the external fcnfences are the only ones of our whole frame which convey clear fcnfations to the parts of the brain. Hence we acquire a natural habit of ascribing all ftrong fcnfations to some external cause. In cafes, therefore, where the caufe of the fcnfation cannot be examined, a falle judgment may easily arise. The languor and pain and various uneasy fcnfations, which a hypochondriac feels, naturally withdraw his attention from surrounding objects; and as the exercife of his judgment is weakened by the fame circumstances, he does not examine the unreasonable ideas with accuracy, when they are first presented to his mind. Painful fcnfations are associated with melancholy thoughts; and new and uncommon fcnfations, upon the fame principle, are ascribed to strange and uncommon caufes. The weaknefs, therefore, which a hypochondriac feels in his limbs, makes him imagine they are unable to support him; but if they cannot do fo, he concludes they must bend or break; the idea of fragility, or flexiblity, however, is often derived from fuch fcnfations as wax and glafs, and lie therefore believes that his limbs are made of fome kind of fillim materials." Loc. cit. p. 208.

In a word, these singular notions of the hypochondriac may be considered as arifting from a long recurrence of novel and distressing fcnfations, connected with a morbid state of the nervous fystem in general, and of the mind or fpirits in particular, which absorb the attention of the individual to the exclusion of common fcnfations: and as the perturbed and agitated mind converts every obscure impression on the fpirit, into visions of horrid form, of the reality of which, if the impressions continue, it conceives a ffirm belief; fo these unnatural fcnfations in the interior of the body become the ground-work of falle and extravagant perceptions.

There is no difficulty in accounting for the ordinary fimp- tions of hypochondriacs, that they are affected with certain dangerous or loathsme difeafes; when it is recollected, that scarcely any organ or portion of the body altogether escapes being the fite of some uneafiness or irregularity of function, which, in the watchful anxiety of the patient's mind, and his disposition to defpicion, at one time becomes the object of his attention and evil forebodings. Like hy- phoria in the female, this difeafe affumes the form, and mimes the symptoms, of almost all other difeafes. When pal- pitations of the heart occur, with intermissions of the pulse, tightnefs in the chest, pulfation in the abdomen, &c. from over-dilution of the flomach by food or flatulency, the hypochondriac
HYPOCHONDRIASIS.

Hypochondriac immediately supposes that hydrothorax, dropsy of the pericardium, aneurism of the heart or of the great artery, auricular paroxysms, or some such formidable disease, with which his reading or enquiries have made him acquainted, is already his lot. If, from sympathy with the name organs, the head is affected with giddiness, or pain, the eyes occasionally dim, the vision double, or otherwise incorrect, the ears affected with a ringing noise, &c. the notion of some disease fixed in the brain immediately occurs, which is at one time supposed to be hydrocephalus, at another an abscess in the brain, or some morbid adhesion among the membranes, &c. And in like manner, every other organ of the body is in its turn believed to be the seat of some fatal and irreremediable malady.

While this general disturbed state of the sensations continues, the sleep is commonly imperfect and interrupted, and every variety of distressing dreams is excited; so that the patients frequently awake suddenly, with startling and in great terror, supposing themselves haunted by all sorts of monsters and visions which imagination can suggest, and suffering much from those oppressive feelings, which are comprehended under the denomination of incubus or night-mare. It is not difficult to conceive, that some of the fancies, entertained by hypochondriacs, may have originated in these dreams, and become rivetted by repetition, from the recurrence of the peculiar fancies which called forth the trains of ideas. See Dreams.

It would be superfluous to attempt to illustrate all the various absurd notions which hypochondriacs have in different infancess entertained, and the strange resolutions which they have formed in consequence; many examples of them are detailed by writers on mental derangement, of which one or two may suffice. Tulpius relates, that a painter of considerable reputation imagined that all his bones were become so soft and pliant, that they must necessarily bend like wax, if he attempted to walk, or if any hard body was struck against them. In conformity with the fears which such a notion inspired, he kept his bed during the whole winter, imagining that if he arose, his legs would be compressed by his own weight into a lump like clay or wax. (See his Off. Med. lib. i. cap. 18.) Marcus Donatus has related, that a baker of Ferrara believed he was made of butter, and on that account would not approach the oven, lest he should melt. (Hist. Med. Rar. lib. ii. cap. 1.) The same author has related the case of a person, the name of Vincentinus, who believed that he was of such an insubstantial frame, that he could not go through the door of his apartment. His physician gave orders that he should be forcibly led through it, which was done accordingly, but not without a fatal effect; for Vincentinus cried out, as he was forced along, that the flesh was torn from his bones, and that his limbs were broken off, of which terrible impression he died in a few days, accusing those who conducted him of being his murderers. (Ibid.) Dr. Darwin had witnessed twice an imaginary itch, and twice an imaginary diarrhœa, when there was not the least vestige of either of these diseases, and once an imaginary deafness, where the patient heard perfectly well; and an imaginary venereal disease, when they had only deceived it, is a very common hallucination among moddly young men. See Zoonomia, vol. ii. clafs iii. p. 1.

Although a great majority of hypochondriacal complaints, especially of the sligher kind, even when they have continued for a considerable time, do not lead to any serious result; yet there are many infinances which the actual state of corporeal disease is ultimately demonstrated, by the termination of the symptoms in dangerous and fatal maladies, such as apoplexy, palsy, jaundice, dropsy, typhany, and pulmonary consumption; not to mention the more complete diseases of the intellect, confirmed mania, melancholy, and insanity, in which they occasionally end. For although the morbid condition of the abdominal viscera may be but slight in the first instance, and will yield to the regimen adopted for its removal; yet diseased vascular action, when long continued, whether idiopathic or sympathetic, frequently leads to morbid structure, to great congealings, and to flow inflammations, with adhesions, effusions of lymph and serum, &c. which are the consequences of the latter. See Whytt on Nervous Disorders, chap. vi.

Causes of Hypochondria. — Some persons are obviously much more liable to hypochondriacal affections than others; and this predisposition to the disease appears to consist in a peculiarity of constitution of the nervous system, and of the digestive organs. This constitution is not always to be distinguished by external character; but it belongs more particularly to the male sex, to the advanced periods of life, and to the melancholy temperament; it is commonly original, or distinguishes the individual from his birth; and is often hereditary, having exiled in his progenitors; but it may be brought on by disease, by improper aliment, and certain modes of life. The disease, however, occasionally takes place in persons of the languid temperament, as we shall state immediately. With respect to the constitution of the digestive organs, it is remarked by Dr. Whytt and Dr. Crichton, that this does not consist solely in debility; since we sometimes see the appetite good, and digestion well performed, on the one hand, and, on the other, we often meet with indigestion and disordered states of the stomach and bowels, in persons who have never suffered any hypochondria. It is to be considered, therefore, as a peculiar sensibility of the nerves of these parts, which are readily put into an unnatural or depraved state of feeling.

The exciting causes are such circumstances as tend to augment or produce this derangement of the chyloneptic viscera, and of the general state of the nervous power. Among these we may enumerate great watching; excessive fatigue; anxious pursuit of business; a sordid life; intemperance in eating; excess in venery; all the depressing passions, however produced, as grief, anxiety, and fear; general repulsion in respect to food, or the use of improper diet; intermittent and remitting fevers. To these most writers on the subject have added, the prevalence of a gouty humour, or the existence of atomic, misplaced or retrocedent gout; the recession of certain cutaneous eruptions; and the retention and suppuration of acuteloned evacuations, as the cutaneous and lichenaceous.

The former of these causes invariably influence the digestive organs, destroy the appetite for food, and render the stomach incapable of converting that which is taken into nutriment; hence the load and oppression after eating, the torpor, sleeplessness, &c. which ensue. At the same time an extreme mobility of the nervous system is induced, especially by exhaustion, from watching, hard study, or any other continued and anxious pursuit, or where there is any severe depreting emotion of mind. These causes, therefore, at once give rise to that disturbed state of the nervous system which takes the alarm at every disagreeable or unsuitable sensation, and to that derangement of the organs of digestion, which, from their peculiar and universal sympathy with every other part of the body, tends to modify those morbid sensations. Hoffmann remarks, that intemperance operates in an additional way, in consequence of the pollution of the fluids; who, in leaning forward immediately after the dinner is digested with food, necessarily occasion a pressure upon the visera of the abdomen, and especially upon the mesentric veins;
HYPOCHONDRIASIS.

veins; whence the circulation through the liver is impeded, and consequently congestion may take place in the various organs of that cavity. (Synt. Med. Ration. tom. 1. lib. ii. cap. 10.) This disease, therefore, has been observed to be particularly frequent in literate men. These congegations have, in fact, formed the subject of that in such cases, Dr. Whytt says, "in the bodies of those who have died of the hypochondriac disease, the mesenteric and other veins which meet to form the vena portae (the great vessel which supplies the liver), have been often found greatly dilated with blood. But," he adds, "this dilation of those veins, if any thing preternatural, was probably only a consequence of some obstruction of the liver, and not to be reckoned, as it has been by some authors, the cause of that distemper." (Loc. cit. chap. 5.) Obstruction by direct pressure on the vena portae mult occasion the same effects on the other abdominal vasa as obstruction in the liver itself; and these effects, Dr. Whytt alleges, are occasioned "by hindering the free circulation of the fluids through these parts, by afflicting their nerves with an uneasie sensation, and by preventing digestion; in the liver and spleen, by impeding the secretion of bile, and, by their weight, occasioning a disagreeable sensation, not only in these, but in the neighbouring parts by sympathy; in the mesentery, by preventing the further preparation of the chyle, and its course towards the thoracic duct; in the uterus and ovaria, by disturbing the functions of these organs; and by confett affecting the stomach and bowels."

The latter causes above-mentioned, especially the previous occurrence of intermitting and remitting fevers, may give rise to hypochondriasis, by their well-known influence on the abdominal vasa, especially the liver and spleen, which they often leave in an enlarged, indurated, or fibrous state; from which the rest of the adjoining organs will be disordered in the way just stated. The observation, that wandering gout, as it has been called, gives rise to these nervous derangements is as old as Aristeus; and Mufgrave, Whytt, and others among the moderns, have borne testimony to the correctness of the observation. It is, however, only an hypothetical expression of the fact, that when a regular fit of gout has occurred, these local and varying complaints have for a time disappeared; but affords no just grounds for the supposition of a morbid humour abode in the fystem. (See Gout and Humoral Pathology.) And in the same manner, the relief of hypochondriacal symptoms, on the appearance of certain purulent, eczematous, or other cutaneous eruptions, has been deemed a further proof that complaints of this kind proceed from some morbid humour in the blood; a notion which we have endeavoured to refute in the articles just referred to. See Whytt, loc. cit. Mufgrave de Arthritis Anomala, cap. 19.

With respect to the proximate cause, or the essential constituent part of the disease, almost all writers have agreed in referring it to a morbid condition of the chymoletic and other abdominal vasa, as we learn from the following enumeration by Dr. Whytt. "Many authors," he observes, "have ascribed this disorder in men to obstructions in the spleen, liver, and mesentery. Highmore to a vitiated constitution of the fystem. (Exercit. de phaumyly et affect. hyphochond.) Willis to an indisposition of the brain and nerves, to a fault of the spirits. Struhalie, who confounds the hypochondriac disease, when in a higher degree, with the fcurvy, has written a dissertation to prove that its seat is not in the spleen, but in the intestines, especially in that part of the colon which lies in the left hypochondre, and where much wind is pent up. (Opera p. 1820.) Sydenham ascribes the same disease to an ataxy or confusion of the spirits. (Epith. ad D. Cole.) Mandeville to a disordered chymollization, and a deficiency or paeuity of the spirits. (Trestise on the hypochond. and hyster. Pallions, Dial. 1. and 2.) Joiner makes the causa praemia of the hypochondriac affection to consist in an obstruction of the blood in the vena portarum and vasa connected with it. (Conspiculus Medicine. p. 186.) Boerhaave derives it from an atablist humour lodging in the pancreas, spleen, stomach, and neighbouring organs. (Aphorian 1896.) Hoffmann from a perverted perspectival motion of the fystem and intestines. (Synt. Med. Ration. tom. iii. p. 5. cap. 5.) And lastly, Dr. Cheyne is of opinion, that all great nervous disorders proceed from some glandular obstruction in the stomach, bowels, liver, spleen, mesentery, or other organs of the lower belly. (Engl. Malady, part ii. cap. 7.)"

It may be observed, then, that the observations of physicians from early times have nearly coincided, in referring the seat of the diseased action, upon which the symptoms of hypochondriacal depend, to the vasa of the abdomen; that the very appellation of the disease is deduced from such observations; that the uneasy sensations of patients, under this disease, are principally ascribed to the same part of the body; and that the disease often terminates in actual morbid structure of the organs there contained. The manner in which the disease in these organs may give rise to the singular morbid sensations in distant organs, has been briefly touched upon above; and those who wish for farther illustration, in regard to the wonderful and widely extended sympathy, which obtains between the alimentary canal and almost the whole fystem, will be gratified by the perusal of the first chapter of Dr. Whytt's treatise, so often referred to in this article. (See also Symptomat.) A very able and experienced teacher in London infers from these facts, which opinion, he alleges, is corroborated by the superior success of a particular mode of treatment, "that the proximate cause of hypochondriasis, in a curative view, consists in a flagitious and irregular state of the hepatic function." Dr. Curry's Syllabus of Lectures at Guy's Hospital, p. 199.

Diagnofis. — There is some difficulty in drawing a precise line of distinction between hypochondriasis, on the one hand, and dysepsia (indigestion), hystera, and melancholia, on the other. This arises partly from the circumstance, that these diseases have all several symptoms in common; that hypochondriasis is often combined with one or other of them; and that they sometimes reciprocally pass into each other. There are few cases of hypochondriasis in which some degree of dysepsia is not present; but Dr. Cullen has pointed out a striking difference in the disease, as it occurs in two different temperaments, or states of the constitution; first, as it occurs in young persons of both sexes, in men of a sanguine temperament, and of a lax and amiable habit; and, secondly, as it occurs in elderly persons of both sexes, in a melancholic temperament, and of a firm and rigid habit. "These two different cases of the combination of vapours and dysepsia," he says, "I consider as two distinct diseases, to be distinguished chiefly by the temperament prevailing in the persons affected. As the dysepsia of sanguine temperaments is often without vapours; and as the vapours, when joined with dysepsia in melancholic temperaments, may be considered as perhaps always a symptom of the affection of the stomach, so to this combination of dysepsia and vapours, I would apply the appellation of dysepsia; and the combination of dysepsia and vapours in melancholic temperaments, as the vapours, or the turn of mind peculiar to the temperament, are essential circumstances of the disease; and as this turn of mind is often with few or only slight symptoms of dysepsia, and
and even though the latter be attending, as they seem to be rather the effects of the general temperament than of any primary or topical affection of the stomach, I consider this combination as a very different disease from the former, and would apply to it strictly the appellation of hypochondriasis.

Dr. Cullen farther remarks, "I believe the affection of the mind is commonly different in the two diseases; in dyspepsia it is often languor and timidity only, easily dispelled; while in hypochondriasis it is generally the gloomy and riveted apprehension of evil. The two diseases are also distinguished by some other circumstances. Dyspepsia, as I have said, is often a symptomatic affection, while hypochondriasis is, perhaps, always a primary and idiopathic disease. As debility may be induced by many different causes, dyspepsia is a frequent disease, while hypochondriasis, depending upon a peculiar temperament, is more rare." Cullen, First Lines, par. 1227 and 1231.

Most of the older writers consider hysterical and hypochondriacal affections as essentially the same, differing no more from each other than as the frame of the female sex, in which, hypochondriacal affections, are more often a source of debility than of the male, which is more liable to hypochondriasis; or insomuch as the one and the other is supposed to be the effect of the disease in the one case, while the other, even, or some contiguous viscus, is believed to be chiefly deranged in the other. The intelligent physician, Fred. Hoffmann, seems to have been one of the first to point out the difference of the two diseases, in respect to their symptoms, causes, and termination. (Med. Rat. Syft. tom. iii. p. 4. cap. 5. § 5 & 6.) There is this obvious difference between hypochondriasis as the disease in question, in regard to the state of the spirits, to wit, while in hypochondriasis there are always in some degree low, insipid, and depressed, and the patient with a greater or lesser degree of apprehension with respect to the state of his bodily health; no pernicious, on the contrary, have a greater flow of high spirits than hysterical patients; and the mental affections, which accompany the former clafs to an opposite one, without any evident cause, or on the slightest imagina, is one of the most remarkable features of the hypochondriacal disease, not to mention the peculiar convulsive paroxysms, the globus, &c. which very frequently accompany the latter. See HYSTERIA.

With regard to the distinction between hypochondriasis and melancholy, an ambiguity has arisen, not only from the one occasionally degenerating into the other, but from the diversity of opinion among medical men, as to the use of the terms. The generality of writers agree in confusing the term hypochondriasis to those infinances of spirits and gloomy apprehensions, which relate exclusively to the personal bodily health of the patient, while they appropriate the term melancholy to those causes in which the dejection and anxiety are fixed upon external relations, as the supposed loss of friends, the imaginary influence of calumny, persecution, &c. In the state of melancholy, too, the digestion is often not impaired, whereas indigestion almost invariably accompanies hypochondriasis; and it may be added, that in hypochondriasis the indigestion precedes this sorrowful state of the mind; whereas, in melancholia, when idiopathic, the state of the mind precedes, and is in a great measure connected with the indigestion. (Sims, in Memoirs of Med. Society of Lond. vol. v. p. 393.) Dr. Crichton has expressed an opinion, that it is of little utility to confine our diagnostic observations to the nature of the erroneous ideas, and he includes a much wider range in his notion of hypochondriasis. Nevertheless, he subscribes in some measure to the distinctions above made, in admitting, that "when hypochondriasis arises primarily from digestive errors, the erroneous ideas, which preface themselves to the mind, generally concern their own frame; but when it has primarily arisen from melancholy, then the morbid ideas are for the most part unnatural, or at least unaccountable fancies, either concerning other people, or their own worldly affairs." (Vol. i. p. 201.) These distinctions are all that are requisite with a practical view, and it is immaterial by what name we designate them, provided we avoid the confusion which an undefined acceptance of ordinary terms must occasion.

Cure of Hypochondriasis.—The method of treatment, required for the removal of hypochondriasis, must necessarily vary in different cases, according to the age, temper, and particular symptoms of different individuals, and the attention of the physician must be directed more or less to the body or to the mental indigitation, accordingly as the one or the other is found to predominate. In all cases, indeed, these two indications must principally be kept in view: 1. To correct the particular dyspeptic or morbid state of the alimentary canal, and of the organs more immediately connected with it; and 2. To occupy the mind with a variety of interesting preoccupations, connected by a natural association, and thus gradually to weaken and destroy the morbid concatenation of ideas which had taken place.

So far as the bodily health is concerned, and especially that of the stomach, it might seem necessary only to have recourse to the usual remedies for indigestion; and that practice has generally been carried on with little distinction but Dr. Cullen has justly pointed out some distinction which is to be made. Where the symptoms of indigestion are particularly urgent, then the same means must be resorted to for their relief, as in cases of simple dyspepsia. Thus, where excess of acidity, which, from the slow evacuation of the stomach in melancholic temperaments, often arises to a high degree in hypochondriasis, occurs, it must be obviated and corrected with the utmost care, by the use of the several antacids, and other means adapted to that purpose. (See Indigestion.) In like manner, the distresses arising from flatulency, heartburn, coffeeine, &c., may be alleviated by the appropriate means. (See the same article; also Car- dialgia, Flatulence, and Constipation.) The point in regard to which Dr. Cullen suggests an important distinction in the treatment of hypochondriasis and simple dyspepsia is, that dyspepsia in.fitue habits, relates to the use of corroboration medicines, to relieve the tone of the stomach. "In dyspepsia," he says, "the chief remedies are the tonic medicines, which to me seem none necessary nor safe in hypochondriasis; for in this there is not a less of tone, but a want of activity that is to be remedied." (First Lines, 1239.) And he suggests, that a practice directly opposed to that employed in the case of dyspepsia is often to be followed. Cold bathing, he observes, is often highly useful to the dyspeptic, and as a general stimulant, may sometimes seem useful to the hypochondriac; but it is not commonly fo to the latter; while, on the other hand, warm bathing, hurtful to the dyspeptic, is often extremely useful to the hypochondriac. Another instance, he says, of a contrary practice necessary in the two diseases, and illustrating the respective nature, is, that the drinking tea and coffee is always hurtful to the dyspeptic, but is commonly extremely useful to the hypochondriac. These observations, however, admit of many exceptions. Chalybeate mineral waters have commonly been employed in hypochondriasis, and seemingly with success. But this, Dr. Cullen justly supposes, is probably to be imputed to the amelioration and exercise usually accompanying the use of these waters, rather than to the tonic power of the small quantity of iron which they contain; and that perhaps the elementary water, by
HYPOCHONDRIASIS.

by favouring the exertions, may have a share in relieving the disease.

One of the most important parts of the medical treatment of hypochondriasis, however, regards the diminution of that torpor and sluggishness, with which the hepatic functions are performed; if this is not accomplished, the other remedies, calculated to obviate the symptoms of dyspepsia, will afford but a brief and temporary alleviation of the disorder. This degree of morbid action in the liver, may be known by attending to the state of the bowels, and of the fecal evacuations from them; by the various colour and odour of which the deficiency or morbid condition of the bilious secretion may be estimated. The most useful treatment consists in maintaining a gentle stimulant operation upon the bowels by means of mild mercurial preparations, varying them in point of strength as the torpor of the alimentary canal is greater or less.

Exercife, as it strengthens the sylem in general, and the chyloupoietic vifera in particular, as it obviates the preflure upon thefe vifera, which a fedentary and fubludus habit occasions, and as it contributes to maintain a free and active circulation through the moft minute portions of the arterial sylem, and thus supports the proper performance of all the functions of secretion, (fee Exercise,) proves a particularly advantageous remedy in hypochondriasis. But it is not lefs useful, perhaps, by its operation on the mind, than by that upon the body, as we shall immediately explain.

The management of the mind, in hypochondriacs, has been considered by Dr. Cullen as the most important part of the treatment, and as often a nice and difficult point. But as it must be admitted, that the morbid perceptions, which characterize the disfane, originate actually in corporeal disturbance; so the state of mind must be considered as a symptomatic and secondary part of the complaint. Nevertheless, as the morbid allocations will be strengthened, if not in any way opposed, after they have once gained admiittance, independently of any increase of the corporeal disfane, they should not be treated with neglect. It must be conceded, therefore, to Dr. Cullen, that "the firm perfuasion which generally prevails in fuch patients, does not allow their feelings to be treated as imaginary, nor their apprehension of danger to be considered as groundless;"—fuch patients therefore are not to be treated either by railing or by reasoning. It is faid to be the manner of hypochondriacs to change often their physician, and indeed they often do it confidently; for a physician who does not admit the reality of the disfane, cannot be fuppofed to take much pains to cure it, or to avert the danger of which he entertains no apprehenlion." Hence Dr. Cullen allows, that if the pious fraud of a placebo be admissible at any time, it seems to be in treating hypochondriacs, even with the bold view to their own security and advantage; for they, ever anxious for relief and fond of medicines, will apply to every source where these are offered, and, though frequently disappointed, will fill take every new drug that can be propofed to them; and thus often become the victims of empiricism and ignorance. The following observations from the able profeflor above quoted, seem to comprehend all that is rational in regard to the mode of occupying the minds of hypochondriacs.

"As it is the nature of man to indulge every preffent emotion, fo the hypochondriac cherifhes his fears, and, attentive to every feeling, finds in trifles light as air a strong confirmation of his apprehenions. His cure therefore depends especially upon the interrupfion of his attention, or upon its being diverted to other objects than his own feelings. Whatever avertion to application of any kind may appear in hypochondriacs, there is nothing more pernicious to them than absolute idlenefs, or a vacancy from all earnest purfuit. It is owing to wealth admitting of indulgence, and leading to the purfuit of tranfitory and unsatisfying amufements, or to that of exhausting pleasures only, that the preffent times exhibit to us fo many infatitudes of hypochondriacism. The occupations of businefs fituate to their circumftances and situation in life, if attended with neither emotion, anxiety, nor fatigue, are always to be adminitered, and perfed in by hypochondriacs. But occupations upon which a man's fortune depends, and which are always therefore, objects of anxiety to melancholic men; and more particularly where fuch occupations are exposed to accidental interruptions, difappointments, and failures, it is from these that the hypochondriac is certainly to be withdrawn.

"The hypochondriac who is not necessarily, by circumftances or habits, engaged in businefs, is to be withdrawn from his attention to his own feelings by some amufement. The various kinds of sport and hunting, as purfued with some ardour, and attended with exercife, if not too violent, are amongst the moft useful. All thofe amufements which are in the open air, joined with moderate exercife, and requiring some dexterity, are generally of ufe. Within doors, company which engages attention, which is willingly yielded to, and is, at the fame time, of a cheerful kind, will be always found of great service. Play, in which fome fkill is required, and where the fate is not an object of much anxiety, if not too long protracted, may be often admitted. In dyspepsias, however, gaming, liable to fudden and confiderable emotions, is dangerous; and the long continuance of it, with night-watching, is violently debilitating. But in melancholies, who commonly excel in fkill, and are lefs fufceptible of violent emotions, it is more admirable, and is often the only amufement that can engage them. Music, to a nice ear, is a hazardous amufement, as long attention to it is very fatigueing.

"It frequently happens, that amufements of every kind are rejected by hypochondriacs; and in that cafe, mechanical means of interrupting thought are the remedies to be fought for. Such is to be found in brilke exercife, which requires some attention in the conduct of it. Walking is seldom of this kind, though, as gratifying to the relife in hypochondriacs, it has fometimes been found ufeful. The required interruption of thought is best obtained by riding on horfeback, or in driving a carriage of any kind. The exercife of falling, except it be in an open boat, engaging some attention, does very little service. Exercife in an early carriage, in the direction of which the traveller takes no part, unless it be upon rough roads, or driven pretty quickly, and with long continuance, is of little advantage.

"Whatever exercife may be employed, it will be most effectual when employed in the purfuit of a journey; firft, because it withdraws a perfon from many objects of unceilnifs and care, which might pefent themfelves at home; secondly, as it engages in more confant exercife, and in a greater degree of it than is commonly taken in airing about home; and, lattly, as it is constantly prefenting new objects which call forth a perfon's attention." Cullen, loc. cit.

We must obferve, however, in conclusion, that the exercifes, thus recommended, operate perhaps equally by retining the corporeal health, as by abracting the attention of the mind from its erroneous perceptions. Upon the fame principle, reafoning with hypochondriacs is commonly useless; for, as Dr. Crichton remarks, although the angular notions which they entertain may now and then be eradicated from their minds by means of a little art, there is fel-
HYP

HYP.

dom any real good to be derived from this, except the
diseafe be at the fame time cured; for if diseased impreffions
continue to arife in the mind from the difordered fecrets,
other illusive notions will spring up as one fet is defroyed.
And we have already alluded to a fatal infurance of a forcible
attempt to convince a hypochondriac of his error by a me-
chanical proof.

HYPOCHROPHYTOS, a flight degree of deafnefs.

HYPOCHYMA, or HYPOCHYMIUM, from υποσ γεναι, under,
and γεναι, to pour, in Surgery, the difeafe usually denominat-
ed a carafac, which was suppoled to proceed from a running
under the cryftalline lens. See Cataract.

HYPOCOSTIS, in Botany. Tournef. t. 477. See Cy-
tinus.

HYPOCINTIS, ηυπος κινητος, formed of υποσ, under, and κινη-
tos, in Medicine, a juice used in the composition of theria, &c.

The hypoctis is the juice of a f foot or excrecence of the
fame name, protruding out of the foot of a kind of ciftus,
or rock-rofe, which is called ledos or ludanijera; common
enough in the hot countries.

The flower grows about three or four inches high; and
one, two, or three inches thick; and is somewhat bigger
at top than at bottom; and is foft, succulent, of a yellowness
and colour, and furrounded from fpaces to fpaces with a fot
of rings, or brownift knots. It bears a number of little bell-
flaped flowers, but no leaves.

When gathered, they pound it in a mortar, and expres-
fs the juice; that done, they evaporate it on the fire till it
come to the confistency of a hard blackifh extract, much like
Spanish liquorice; then they make it up into little maffes
for carriage. It is a mild astringent, of no particular smell
or flavour, and recommended for fopping flusks of the belly,
voomings, and hemorrhages; though anciently much more
than prefent. It is also an ingredient in fome ingemts.

It is fometimes ufed as a fubstitute to acacia. — Dr. Quincy
says, it is the more powerful alluring of the two.

HYPOCRANIUM, in Surgery, signifies an afbeccs
under the cranium, between the bone and dura matter.
The term is derived from υπος, under, and χρανη, the skull.

HYPOCRAS. See Hippocras.

HYPOCRATERIFORMIS, Sancer-flapfed, in Botany,
the name given by Mr. Tournefort to a peculiar fort of flow-
ers of plants, of the general order of the infundibuliform,
but not fo deep and narrow at the mouth as thofe fimpify so
called, but expanded into the figure of a faucer.

HYPOCRINE, or Hippocrine. See Helicon.

HYPOCRISY, ηυποκρισις, in Ethics, denoted difsimulation
with regard to the moral or religious character.

HYPODIACONORUM FESTUM. See Calendarium.

HYPDIEZEUHS, in Music, according to Bachi-
us, is, the interval of a fifth between two tetradhrons
separated by a dijsijion, and further by a third interme-
diate tetradhron. Tlius there is a hypo-diezeugus between
the tetradhrons hypatus and diezeugumen, and between the
tetradhrons sylphemenon and hyperbolon. See Tetrachord.

HYPDORIAN, the lowest of all the modes of An-
cient Music. It has its fundamental a fourth below that of
the Dorian mode. It is faid to have been invented by Pli-
louccus. This mode is grand, but cheerful: uniting sweet-
nefs with majesty.

HYPEDROM. See Hippodrom.

HYPOEDES, in Botany, a name given by Dr. Sol-
lander, who meant to write it Hypoefes, from υπος εδες, an
inner segment or covering, expressive of the minute membra-

Claf and order, Diandria Monogynia. Nat. Ord. Perfonata
four-leafed three-flowered involucre. Corolla two-lipped.

A genus separated from Jaffica by Solander and Brown,
containing of canadement herbs or thistles. The involucrons,
naturally three-flowered, though sometimes, by abortion,
single-flowered, grow oppofite, in axillary or terminal spikes,
accompanied by leafy bractes. The flowers are either
purple or white. Within the proper calyx is a small white
membraneous integument.

Examples of this genus are found in the firft fection of
Wildenow's Jiffica, as J. fuficosa, Lind. Mant. 172.
Val. Symb. v. t. t. lent by Koenig from Tranquicar.
To this is nearly allied J. Forfkei of Val.

Mr. Brown found a new species in the tropical part of
New Holland, which he denominates H. floribunda.

HYPOLAEUM, ευπολαιος, formed of υπο- under, and λα-
ειον lighted, in the Ancient Architecture, is a name com-
mmon to all the parts of a building that are under ground;
the cellar, batteries, and the like places.

The term hypolaeum was ufed by the Greeks and Romans
for fulferaneous toms in which they buried their dead.

HYPOLAEUM, ευπολαιος, in Agriculture, is a name given to
the eleffial houses which are below the horizon; and espe-
cially the innum cells, or bottom of heaven.

HYPOLAEUS, from υπος, under, and λαειον, lighted,
which, in Botany, is a name under which the internal ilaces
is often defribed, as the corresponding
vein is also called the hypogallic. More commonly,
however, the name is given to thofe continuations of
the trunks of the internal ilaces, which afcend along the fides
of the bladder to the umbilicus, where they take the name
of umbilical. They go to the place of
their defcription.

HYPOLAEUS Region, is the lower portion of the ab-
dominal cavity. See Abdomen.

HYPOLAEUS is the fame with the HYPOLAEU-
GRIC Region; which fee.

HYPOLAEUSCELE, from υπολαιος, and κελευ
ho, a tumour, in Surgery, a ventral hernia. See Hernia.

HYPOLAEUSTUM, in Botany. See Ruscus.

HYPOLAEUS, in Anatomy, from υπος, under, and λα-
ειος, the tongue, the nerve of the ninth pair, so called
from its situation under the tongue.

HYPOLAEUS, or Hypolaeus, composed of υπος, under,
and λαειος, tongue, is a name given to two glands
of the tongue.

There are four fławes of glands of the tongue; two of them
called hypoglotides, situated under it, near the venes
ranulares; one on each fide of the tongue. They ferve to
filtrate a kind of fervous matter, of the nature of saliva, which
they difcharge into the mouth by little ducts near the gums.

HYPOLAEUS, or Hypolaeus, in Medicine, denotes an
inflammation or ulceration under the tongue; called also
ranula.

HYPOLAEUS, in Music. See Hypolaeus.

HYPOLAEUS, the fecund of the modes of Ancient
Music from the lowefl: Enclid calls it aypo-itarian, and
graft Phrygian. Its fundamental is a fourth below the
Dorian mode.

HYPOLAEUS, or Hypolaeus, in Botany, from υπος, under,
and λαειος, a branch, or covering, alluding to the short integument
HYP

Female, Cal. scales numerous, imbricated. Perianth a hulk of six leaves, terminal, solitary. Style in two or three divisions, deciduous. Nut bony, naked, single-seeded, longer than the perianth.

A genus established by Mr. Brown, who observes, that it has the habit as well as the male flowers, of *Reflca*, for which reason, as well as on account of the want of a lobed external appendage to the perianth, he has separated it from the *Wildenowia* of Thunberg, whose fruit is similar, but its male indorfence (not well described by Thunberg), and its habit are different.

The species are,

Both grow in various of the coater parts of New Holland.

**HypoLepis**, from *i-zo*, under, and *kai*, a scale. Peroon Syn. v. 2. 598. The same; plant as *Phedrae fangiuna* of Thunberg and Wildenow. See Phily-

**HYPOLYDIAN**, the fifth mode of the *Ancient Mus", beginning from the lowest. Euclid calls it hypolai- tan and hypo-lyrian. Its fundamental is a fourth below the Lydian. Euclid distinguishes two hypo-lydian modes; the acute, that is this of that article, and the grave, which is the same as the hypo-olian.

The hypo-lydian mode was proper for funeral chants, sublime and divine meditations: its invention is attributed by some to Polycyntites of Colophon, by others to Damou of Athens.

**Hypolytrum**, in *Botany*, from *i-zo*, under, and *kai*, a cover, or scale, on account, as we presume, of the internal scale covering of the seeds. Peroon Syn. v. 1. 75. Clas and order, *Triandra Monogynia*. Nat. Ord. Cylamaria, Linn. Cylamari. Jaff.

Eff. Ch. "Scales imbricated every way. Seeds with an internal cover, reembling a glume of three or four valves. Stamens two or three. Stigmas one or two." Peroon.

This is supposed to be the same genus with *Hypolytrum*, (see that article,) and even their names are perhaps originally the same. Peroon defines three species, *H. latifolium*, *finis-

"*zoo*, and *gai*, all communicated by M. Richard. Their definitions, however, do not accord with our above-

Figure their species of *Hypolytrum*.

**Hypo-MIXO-LYDIAN**, a mode added by Guido d'Arezzo to the *Ancient Mus", the plagal of the mixo-lydian mode, and its fundamental is the same as that of the Dorian mode.

**HYPOMNEMATOGRAHUS**, from *i-zo*, *kai*, *gai*, *kai*, derived from *kay*, *kai*, *gai*, *kai*, *kai*, *kai*, *kai*, *kai*; in the *Primitive Church*, an officer who attended on the bisho,

"*Upomochlion*, formed of *i-zo*, under, and *kai*, *kai*, *kai*, *kai*, in Mechanics, the fulcrum of a lever, or the point which sustains its prejudice, when employed either in raising or lowering bodies.

The hypomochlion is frequently a roller set under the lever; or under flames, pieces of timber, &c. that they may be the more easily lifted up, or removed.

**HypoNITIS**, in *Botany*, a name given by Dilleniust to a genus of plants, called by Tournefort orobanchoides. See Monotropina.

**HYPOMNEMATOGRAPHUS**, in *Surgery*, from *kai*, under, and *kai*, a phlegmatic ulcer, a deep phlegmetic ulcer.

**Hypophora**, from *kai*, in *Rhetoric*, the first part of the prolepsis, thus, in the following instance: "but some men will lay, how are the dead raised, or with what body do they come?" is the hypophora; and, thou fool, that which thou foulest, &c. is the anthypophora, or solution of the ob-

**HypoPITIS**, in *Surgery*, a deep, fistulous ulcer, from *i-zo*, under, to be carried underneath.

**Hypo-PHYRIGIAN**, one of the modes of *Ancient Mu-

"*Upopherthyalum", from *i-zo*, under, and *kai*, *kai*, *kai*, the eye, in *Surgery*, denotes a swelling, which sometimes takes place under the eye in cafes of dropy and cachexy.

**HypoPITIS**, in *Botany*, a name used by some authors for the eye. See Hypophila.

**HypoPhyllocarpodendron**, in *Botany*, Dill. Gen. 7. See Monotropia.

**HypoPodium**, in *Antiquity*, a piece of furniture belonging to the battle: its use was to set or rest the feet on, as the name imports.

**Hypo-ProLAMABANOMENOS**, in *Music*, the name of an additional fire or sound, which Guido is said to have added to the scale of the Greeks, a note below prolambanomenos, answering to gamut or G on the first line in the bate. The author of this new found expressed it by the letter s, gamma of the Greek alphabet, whence the name of gamut was derived. See Diograp.

**HypoPoyon**, or *Hypophyson*, is a term in *Surgery*, usu-

"*Upophora*, from *kai*, *kai*, *kai*, *kai*, the eye, an ecchymo-

"*Upophyson*, in *Botany*, Dill. Gen. 7. See Monotropia.
HYPOPYON.

Hypopyon, when it is a consequence of inflammation, can only proceed from a violent degree of it, and it commonly makes its appearance under the following symptoms. The pain is throbbing and acute, and instead of being confined to the eye-ball and upper part of the forehead extends as far as the back of the head. All on a sudden, however, upon the attack of a shivering fit, it undergoes a diminution, and it is at this period that the first drop of matter generally makes its appearance at the bottom of the anterior chamber, in the form of a febrile whitish specie, which, in proportion as the quantity increases, gradually becomes larger, spreads upwards, covers the pupil, and at length occupies the whole of the anterior chamber. In this state, the cornea exhibits everywhere a white appearance. The progress of the disease is various. When the case is left to take its own course, the pain often becomes again excessively severe, and no alleviation is experienced, till the matter makes its way through the cornea, and escapes, together with the aqueous humour, and, in general, a considerable portion of the vitreous. The pain immediately abates; but the eye is irrecoverably destroyed. In favourable cases, the matter, with the aid of proper means, is entirely dispersed. Sometimes it is only partly absorbed, and a portion continues, either upon the surface of the cornea, upon the surface of the cryftalline lens, or in the pupil, so as to produce either total blindness, or a material impairment of vision.

The matter of hypopyon is commonly represented to be pus; but Scarpa, the celebrated surgeon at Pavia, adopts the opinion, that it is only coagulated lymph, which is exhaled from the highly inflamed choroides and uvea in severe ophthalmies affecting the interior of the eye.

While the violence of the inflammation of the eye lasts, the hypopyon never fails to enlarge; but as soon as this phase ceases, and the ophthalmia fails into its second period, or that attended with local weaknesses, the matter in the anterior chamber receives no longer any addition, and, from that moment, is disposed to diminish. See Scarpa Sulle Malattie degli Occhi.

Surgical writers have recorded curious examples of a periodical species of hypopyon. A man, of a bad habit of body, became blind the first fortnight of every month. A yellowish matter, which was so thick and opaque as to conceal the iris, could always at this time be remarked in the anterior chamber. The conjunctiva was also inflamed; but not painful. On the fourteenth day of each month these complaints used to disappear, and the fight to return. (Janin Mémoires sur l'Oeil, p. 412.) Another person was deprived of his eye-light every morning, and, during the attack, the aqueous humour was always very turbid. The patient at the same time regularly suffered pain under the short ribs, on the right side. The paroxysm constantly terminated upon a copious discharge of air being made from the alimentary canal. See Richter's Anfangsgründe Band 3, p. 97.

The treatment of hypopyon consists either in attempting to disperse the matter collected in the anterior or posterior chamber, or else in making an incision for its evacuation. Against the latter proceeding, as a general one, Scarpa has urged several weighty considerations, as we shall presently notice.

The tendency of an hypopyon to diminish, as soon as the first violence of the ophthalmia is over, shews, according to Scarpa's judgment, how important it is, in order to check the progress of hypopyon, to employ the most powerful means for subduing the first severity of the inflammation of the eye. With this view, copious evacuations of blood, both generally and topically, are recommended. When chemosis prevails, the conjunctiva is to be divided. Mild aperients, blisters to the nape of the neck, little bags of emollient herbs applied to the eye, and other measures for the relief of the first stage of severe ophthalmia, are highly necessary. These will be known to have fulfilled the desired end, by the abatement of the lancing pains in the eye, the ceasing of the febrile symptoms, the restoration of the free motion of the eye, and the hypopyon no longer continuing to increase. The first measures have now answered every expectation, notwithstanding the eyelids and conjunctiva may still be affected with a degree of redness. The lower orders of people are frequently seen in the second stage of acute ophthalmia, going about with an hypopyon, and making no complaint whatever of any of the febrile sufferings always attendant on the first stage of acute ophthalmia. It is only at this crisis, or at the termination of the acute stage of violent inflammation of the eye, that the hypopyon ceases to enlarge, and begins to be absorbed, provided this fatal procedure be not impeded by any wrong plans. Scarpa recommends against making an incision in the cornea to let out the matter; a plan which has been commonly taught by surgical authors, and which has been extensively adopted, but which most frequently gives rise to evils worse than hypopyon itself, and this, notwithstanding Richter's advice be followed, not to let out all the matter at once, and not to promote its exit by pressure or injections. Scarpa assures us, that a wound in the lower part of the cornea, how small ever it may be, most commonly re-produces the severe acute ophthalmia, and occasions a large extravasation of lymph, or matter in the chambers of the aqueous humour. Besides, after opening the cornea, the matter, if left to itself, would be several days in becoming entirely discharged, during which time it would keep the edges of the wound austerely, and make them suppurate. In this manner the cut would be changed into an ulcer, through which the aqueous humour would escape, and in all probability a fold of the iris be protruded. Even the cryftalline lens itself might fall out. No arguments in favour of the practice can justly be drawn from the successful result of certain cases, in which the hypopyon spontaneously buries. Scarpa reminds us that there is a wide difference between the effects of a spontaneous opening into a natural or preternatural cavity of the animal body, or of one made with cautfe, and the consequences of an opening made with a cutting instrument. In the two first methods the subsequent symptoms are constantly milder than in the last. Besides, the fact is, that when an hypopyon discharges itself through an ulcerated opening, it not unfrequently happens that not only the aqueous humour escapes, but a prolapsus of the iris also happens.

Scarpa only admits the utility and necessity of dividing the cornea, when the coagulating lymph, or matter of an hypopyon, exils in very large quantity, and produces such distortion of the eye, and such urgent symptoms, as put the patient's life into danger. Besides menacing a total destruction of the affected organ.

It is maintained by this distinguished anatomist and surgeon, that as the fragments of cataracts, when pushed through the pupil into the anterior chamber of the aqueous humour, are
in time absorbed, there cannot be a doubt that the coagulating lymph, in the example of hypopium, also admits of being taken away by the absorbents, as soon as a further extravasation no longer goes on, and the lymphatics begin to recover their action. Scarpa, therefore, inculcates that the resolution of an hypopium is the first thing which the surgeon ought to aim at in the treatment of the common form of the disease, and that the best method of doing this is to subdue the first velenome of the acute ophthalmy by antiphlogistic remedies, and mild, emollient, topical applications.

When success attends this plan, as it does in the generality of cases, the hypopium not only ceases to enlarge, but begins to diminish, in proportion as the violence of the inflammation abates.

Various remedies have been recommended for the purpose of dispersing the matter collected in the chambers of the aqueous humour. Monseur Janin was of opinion, that when the matter disappeared, it was not absorbed, but exuded through the pores of the cornea. His advice, consequently, was to endeavour to make the pores of this membrane as pervious as possible, by the topical employment of emollient applications, so as to promote the escape of the matter. For this object he recommends the decocum malvae, as exceedingly efficacious. He used to bathe the eye several times a day with this remedy, and in the intervals apply compresses wet with the same. Janin assures us, that even when both the chambers of the eye were full of matter, and the cornea seemed likely to burst, this method proved successful, the dissection being generally effected in about twelve or fourteen days. There can be no doubt that benefit has been derived from using the decocum malvae, especially as Peller and other eminent oculists confirm the accounts of the good effects of the application. But we believe with Scarpa, that it is by no means superior to several other remedies, and that every topical emollient application, if connected with such internal antiphlogistic treatment as is the most proper for repelling the acute stage of the severe ophthalmy, would be equally beneficial. More warm water is productive of quite as much good.

With respect to Janin's notion of the matter of the hypopium exuding through the pores of the cornea, the opinion is altogether defective of foundation. Richter rightly maintains, that when an hypopium is dispersed, there are no appearances in support of such a sentiment. When blood is extravasated in the anterior chamber, and afterwards disappears, it must be by absorption, for if it exuded out of the cornea, it would be visible upon the surface or in the subdivision of this transparent membrane.

Woolhouse recommends, for the dispersion of an hypopium, the application of a poultice, made of the pulp of a roasted apple, and containing a small proportion of camphor. Giesen advises the use of a collyrium, composèd of rose-water, muriate of ammonia, aloes, and myrrh. Mau- chart speaks in favour of warm collyria, and of fomenting the eye.

We decidedly join Richter in thinking, that, as the eye is in general violently inflamed, all irritating applications must be hurtful and improper. Little benefit can be expected from any remedies which only come in contact with the eye-lids, as, for instance, Woolhouse's poultice. But, supposing the applications to act more extensively, they can hardly operate effectually upon the surfaces, by which the matter of the hypopium is secreted. Some good, however, will result from emollient's, and much more may reasonably be expected from such means as tend to excite and quicken the action of the absorbents, as, for example, antimonials, aperients, bleedings, blisters on the nape of the neck, or behind the ears, &c. These remedies not only promote the absorption of the matter, they likewise have a powerful effect in putting a stop to the inflammation.

When the first stage of severe ophthalmy has reftilled the bellies of treatment, or when these have been practised too late, the matter in the chambers of the eye is occasionally abundant, after the first stage of the ophthalmy has passed, that it continues for a long while to obstruct vision. Scarpa has often seen patients, especially paupers, who, from negligence or wrong treatment, have remained a great while after the cessation of the acute stage of an ophthalmy, with the anterior chamber almost entirely filled with the glutinous matter of hypopium. When the inflammation ceases, these persons are described as wandering about the streets with great unconcern, and having no affliction but the impairment of their sight. In this second stage of ophthalmy, the hypopium cannot be dispersed, either too speedily, or by exactly the same treatment as in the first stage. In a case of this description, Scarpa recommends such remedies as are most calculated to invigorate the debilitated tone of the vascular system of the eye, particularly the lymphatics. The time necessary for the completion of this object will vary according to the patient's age and the nature of his constitution.

The surgeon ought carefully to try the degree of irritating in the eye, by introducing, between the globe and the eye-lids, a few drops of a collyrium, containing some sulphate of zinc, and mucilage of quince-feeds. Should the eye seem too strongly inflamed by this application, it must not be used, and little bags, filled with warm marshalls and a few grains of camphor, are to be substituted for it. In the intervals the vapour of the spiritus ammoniac comp. may be applied to the eye. A blinder is also to be put on the nape of the neck. As soon as the eye will easily bear the vitriolic collyrium, this is to be employed, and its strength may afterwards be gradually increased by the addition of a few drops of camphorated spirit.

Under such treatment, the hypopium may often be observed to disappear regularly as the chronic ophthalmy is removed.

We are not, however, always to expect to be thus success-ful with regard to hypopium, attended either with the first or second stage of ophthalmy. When the extravasated matter strongly dilates the chambers of the aqueous humour, and the cornea in particular, the most skillful treatment will sometimes not avail in preventing ulceration, opacity, and the bursting of the central part of the cornea.

When the ulcerated opening is formed, some of the matter of the hypopium escapes, and a degree of amendment follows; but the relief is only of short continuance, as a portion of the iris is soon protruded through the aperture. If, in an urgent case of this kind, the bursting of the cornea were not speedily to happen, the violent symptoms depending upon the diffusion of the eye-ball would compel the surgeon to make an opening in that membrane. This form of the disease is described as being excessively severe, and even attended with danger. The head-ache, and pain in the eye, are frequently so grievous as to occasion delirious symptoms. According to Scarpa, the surgeon may the more readily make up his mind to practise an incision, as there is hardly any hope of saving the eye.

Should there be any reasonable chance of restoring the transparency of the cornea, and of preserving the eye, Scarpa approves of opening this membrane at its lower part, just as is done in the operation of extracting the cataract. But when no such pleasing prospect occurs, he thinks the best and quickest way of relieving the severe pain of the hypopium, is to introduce across the central point of the cornea...
vea a small bistoury, so as to make a cut about one line and
a half broad. The little flap is then to be raised with fer-
ceps, and removed with one stroke of a pair of scissors.

The opening, thus made, will not be liable to close like
a simple incision. The fluid part of the matter immediately
escapes, and reft some time afterwards, followed, sooner or
later, by the clyndulline lens and vitreous humour.

As soon as the operation is done, a bread and milk pou-
tice is to be applied, and care taken to change it every two
hours. At the same time such means are indicated as are
most calculated to avert and diminish inflammation, and to
oath nervous irritation. The eye gradually suppurates and heals,
after which it is generally in a lato to admit of the applica-
tion of an artificial eye. See EYE, Artificial.

Although Scarpa fations the performance of an incision
in the foregoing case of hypopion, which is attended with
urgent, disturbing, and perilous symptoms, he maintains that
the practice is highly improper in common inancies, for rea-
sons already explained.

With respect to cutting out a piece of the centre of the
cornea, as it is advised by Scarpa, we feel persuaded that
nothing can justify this proceeding unless it is decided cer-
tain that the eye and eye-ight are beyond recovery. In
any other circumstance, the incision should undoubtedly be
executed, as in the extraction of the cataract. See Cata-
ract.

HYPOCHEMA, formed of τρεπτικός, I accommodate
my dancing to a singing chorus, of ἑτερος and χόρος, I dance, in
the Greek Poetry, a poem composed of divers kinds of verbs,
and of different lengths; but always very short, and full of
Pyrrhic feet. This poem was composed either to be sung
or played with the flute or cithara, but to regulate a dance
according to the sound of voices and instruments. Proclus
says, it was a dance accompanied with a song. These were,
probably, the origin of the Italian Ballata; which see.

HYPORISMA, in Surgery, an aneurism.

HYPOSCHENIUM, τρεπτικός, in Antiquity, a partition
under the pulpit or logeum of the Greek theatre, appointed
for the music.

HYPOSESCHIS, τρεπτικός, in Rhetoric, the fame with
division.

HYPOSPADIAS, in Surgery, from ἑτερος, under, and σπανός,
I draw, a Greek name anciently given to a person, who had
the orifice of the canal of the ureter not directly at the ex-
tremity of the gland. Gelan applies the fame name to thole,
the frenum of whose penis is too short, on which account it
is bent in erection; this is easily remedied by cutting the
ligament, and washing the wound with warm wine.

HYPOSEPATHISMUS, in the Ancient Surgery, an
operation practifed, by making three incisions in the forehead,
to the very bone, about two inches long; in order to cut or
divide all the vessels between those incisions. The design
of the operation was to prevent defluxions on the eyes.

The word is τρεπτικός, formed of ἑτερος, under, and σπανός,
spatula; by reason after incisions were made they thrust a
spatula all along between the pericranium and the bill.

HYPOSPHAGMA, in Surgery, a contusion of the eye,
attended with ecchymosis; a black eye.

HYPOSTAPHYLE, from ἑτερος, under, and σπανός, the
ulula, a relaxation, or elongation of the ulula.

HYPOSTASIS, τρεπτικός, compound of ἑτερος, under,
and σπανός, I stand, I cease, q. d. subfiliation, a Greek term,
literally signifying subfiance, or subfidence; it is used in the-
logy for person.

Thus fome have held that there is but one nature or
feence in God, but three hypofies, or persons.

The term hypofies is of a very ancient standing in the
church. St. Cyril repeats it divers times, as also the phrase,
union according to hypofies. The first time it occurs in all
Christian antiquity, in a letter of that father to Nellorius,
where he ues it instead of προσεκολασία, the word we commonly
render person, which did not seem expressive enough. "The
philofophers, fays St. Cyril, have allowed three hypofies:
they have extended the divinity to three hypofies: they
have even sometimes ufed the word Trinity; and nothing
was wanting but to have admitted the confubftantiality of
the three hypofies, to thye the unity of the divine nature,
exclusive of all triplcity in refpect of diñffection of nature,
and not to hold it neceffary to conceive any refpective inferiority
of hypofies."

This term has occasionally great diffentions in the ancient
church; f��rst among the Greeks, and afterwards also among
the Latins.

In the council of Nice, hypopion was defined to denote
the fame with (fence, or subfance; fo that it was hereby to
fay, that Jesus Christ was of a different hypopion from the
Father; but custom altered its meaning. See Trinity

HYPOSTASIS, in Medicine, the sediment of the urine,
or that thick heavy part of the urine which fubfides and fettles
at bottom.

HYPOSTATICAL, in Theology, is a term used in speak-
ing of the mystery of the incarnation.

A hypofical union, is a phrase used by fome divines for
the union of the human nature with the divine in the perfon
of Jesus Christ.

HYPOSTATICAL Principles, among the Cenmites, and par-
ticularly the Paracelfhis, are the three chemical elements, fiirit,
fulphur, and mercury; called also the iris prima. See Prin-
ciple and Element.

HYPO-SYMNAPHE, in the Greek Music, the disjunction
of two tetrachords separated by the interpolation of a third
tetrachord conjoint with both; fo that the homologous or
relative ftrings of the two tetrachords, disjoined by the hyp-
fynaphe, have the interval of five tones, or a minor feventh
between them. Such are the two hypoton and fymmenon
tetrachords.

HYPOTHECA, in the Civil Law, an obligation,
whereby the effects of a debtor are made over to his creditor,
to secure his debt.

The word comes from the Greek, ἑτερος, a thing sub-
ject to some obligation; of the verb ἑτερος, I sub-
ject; of ἑτερος, under, and ἑτερος, pono, I put.

As the hypotheca is an engagement procured on purpose
for the security of the creditor, various means have been
made ufe of to secure him the beneﬁt of the conuention.
The ufe of the pawn or pledge is the most ancient, which is
almost the fame thing with the hypotheca; all the difference
conﬁning in this, that the pledge is put into the creditor’s
hands; whereas, in a simple hypotheca, the thing remained
in the poifession of the debtor. It was found more easy
and commodious to engage an eftate by a civil covenant than
by an actual delivery: accordingly, the expedient was ﬁrst
practifed among the Greeks; and from them the Romans
borrowed both the name and the thing: only the Greeks,
the better to prevent frauds, ued to ﬁx fome visible mark
on the thing, that the public might know it was hypotheca,
and mortgaged by the proprietor; but the Romans, looking
on fuch advertisements as injurious to the debtor, forbid the
ufe of them.

The Roman lawyers diftinguifh four kinds of hypo-
theas: the conventional, which was with the will and
condent of both parties; the legal, which was appointed by law,
and for that reafon called tacit; the priets pledge, when
by the fight or non-appearing of the debtor, the creditor was put
HYP

put in possession of his effects; and the judiciary, when the creditor was put in possession by virtue of the sentence of the court.

The conventional hypothesis is subdivided into general and special. The hypothesis is general, when all the debtor's effects, both present and future, are engaged to the creditor. It is special, when limited to one or more particular things.

For the tacit-hypothesis, the civilians reckon no less than twenty-six different species thereof.

HYPOTHECATE, from the Latin hypotheca, a pledge; to hypothecate a ship, is to pawn the same for necessaries; and a matter may hypothecate either ship or goods, for relief, when in dittrefs at sea. For he represents the traders as well as the owners; and in whose hands forever a ship or goods hypothecated come, they are liable. 1 Salk. 34. 2 Litt. Abrid. 95.

HYPOTHEMACARPI, in Anatomy, a name given by Winfrow to two muscles of the little finger. The abductor minimi digitii is his hypothemarcarpi minor; and the adductor of his metacarpi minimi digitii is the hypothemarcarpi major.

HYPOTHENUSE, or rather HYPOTENUSE, formé de subestens, subestens, formed de subestens, I subestens, in Geometry, is the longest side of a right-angled triangle; or that side which subtends, or is opposite to the right angle.

Thus in the triangle ABC (Plate VIII. Geometry, fig. 100.) the side AC, opposite to the right angle A BC, is called the hypotenuse.

It is a celebrated theorem in geometry, that in every rectilinear right-angled triangle, as ABC, the square of the hypotenuse, AC, is equal to the squares of both the other sides, AB and BC. This is particularly called the Pythagorean theorem, from its inventor Pythagoras, who is said to have sacrificed a whole hecatomb to the Muses, in gratitude for the discovery. For proof of this theorem, let A D be the square on the hypotenuse AC, and B G, B I, the two squares on the sides A B and B C; let M B H be parallel to A E, meeting G F, produced, in H; and let E A H produced to meet G H in N, and D C to meet I K in O. If from the equal right angles G A B, C A N, the angle N A B, common to both, be taken away, there will remain N A G = B A C; whence, as the angle G is also = A B C, and the side A G = A B, the sides A N and A C (= A E) are likewise equal; and therefore the parallelogram A M = the parallelogram A H (being both on equal bases and between the same parallels); which last, and consequently the former, is equal to the square B G, standing on the same base A B, and between the same parallels. By the same mode of reasoning, the parallelogram C M is = the square B I; and, consequently, the square A D (= A M + C M) = both the squares B G and B I. The same reasoning is applicable to circles or any other similar figures; viz. that any figure described on the hypotenuse is equal to the sum of the two similar figures described on both the other two sides.

HYPOTHESES, hypothesi, formé de hypothe, under, and theo, poserre, of theo, to see, I put, in Logic, is a proposition or principle which we suppose, or take for granted, in order to draw conclusions for the proof of a point in question.

In disputation, they frequently make false hypotheses, in order to draw their antagonists into absurdities; and even in geometry, truths are often deducible from such false hypotheses.

Every conditional or hypothetical proposition may be distinguished into hypothesis and thesis: the first rehearses the conditions under which any thing is affirmed or denied; and the latter is the thing itself affirmed or denied.

Thus in the proposition, a triangle is half of a parallel-ogram, if the bases and altitudes of the two be equal; the latter part is the thesis, if the bases, &c. and the former the hypothesis, a triangle is half a parallelogram.

In strict logic, we are never to pass from the hypothesis to the thesis; that is, the principle supposed must be proved to be true, before we require the consequence to be allowed. Dr. Barrow says, that hypotheses, or postulates, are propositions affirming or affirming some evidently possible mode, action, or motion of a thing, and that there is the same affinity between hypotheses and propositions, as between axioms and theorems; a problem shewing the manner, and demonstrating the possibility of some structure, and an hypothesis affirming some construction which is manifestly possible.

HYPOTHESE, in Physics, &c. denotes a kind of system laid down from our own imagination, by which to account for some phenomenon or appearance of nature.

Thus we have hypotheses to account for gravity, for magnetism, for the deluge, &c.

The real and scientific causes of natural things generally lie very deep: observation and experiment, the proper means of arriving at them, are in most cases extremely slow; and the human mind is very impatient: hence we are frequently driven to feign or invent something that may seem like the cause, and which is calculated to answer the several phenomena, so that it may possibly be the true cause.

Philosophers are divided as to the use of such fictions or hypotheses, which are much less current now than they were formerly. The latest and best writers are for excluding hypotheses, and standing wholly on observation and experiment.

Whatever is not deduced from phenomena, says Sir Isaac Newton, is an hypothesis; and hypotheses, whether metaphysical or physical, or mechanical, or of occult qualities, have no place in experimental philosophy. Phil. Nat. Prin. Math. in cause.

The Cartesians take upon them to supposse what affections in the primary particles of matter they please; just what figures, what magnitudes, what motions, and what situations, they find for their purpose. They also feign certain unclean, unknown fluids, and endue them with the most arbitrary properties; give them a subtlity which enables them to pervade the pores of all bodies, and make them agitated with the most unaccountable motions. But is not this to set aside the real constitution of things, and to subliminate dreams in their place? Truth is scarcely attainable even by the surest observations; and will fanciful conjectures ever come at it? They who found their speculations on hypotheses, even though they argue from them regularly, according to the trite rules of mechanics, may be said to compose an elegant and artful fable; but it is still only a fable. Cotes in Prefat. ad Newton. Princip.

HYPOTHESES is more particularly applied, in Astronomy, to the several systems of the heavens; or the divers manners wherein different astronomers have supposeth the heavenly bodies to be ranged, moved, &c.

The principal hypotheses are the Ptolemaic, Copernican, and Tychoantic.

The Copernican is now become so current, and is so well warranted by observation, that the advocates of it hold it injurious to call it an hypothesis.

HYPOTHETICAL Proposition and Syllogism. See CONDITIONAL.

HYBOTRACHELION, from hypo, under, and tracheia, neck, in Anatomy, denotes the lower part of the neck.

HYBOTRACHELION, in Architecture, is used for a little frieze in the Tuscan and Doric capital, between the astragal and annulet; called also the collar and gorget.
The word is also applied by some authors, in a more general sense, to the neck of any column; or that part of the capital thereof below the acroter.

HYPOTYPOSIS, or Imagery, εἰμάτωσις, formed of the verb εἰμάτωσιν, per figuram demonstro, I fove, represent, or make anything to be seen; of εἰμί, under, and νοος, type, image, resemblance, in Rhetoric, a figure whereby a thing is described or painted in such strong and bright colours, that it does not seem to be read, or heard, but actually seen, or presented before the eye.

Such is that elegant one of Cicero, wherein he paints the barbarity of Verres: 'Ipsa inflammatus fœcere et furere, in forum venit. Ardaeulificant; turo ex ore crudelitas emanat. Exspectandam omnes quo tandem progreffurum, aut quidnam actus efl? cum repente hominem corrigit, atque in furro modo nudari ac deligari, et virgas expedire jubet. Clamatam ille mifer se civen esse Romanum, &c.' Such is also the picture which he has drawn of Catiline, confuting of an unaccountable mixture of contrary qualities.

Pro. C.æ. c. 5.

The hypotyposis is frequently used by the poets, and particularly Virgil, who abounds in paintings.

This figure is peculiarly suited for drawing characters, and often affords the finest ornaments in poetry and history, as well as oratory. It is also adapted to move and interest different passions, according to the nature of the subject, and the artful management of the speaker.

Gen. Ch. Cal. none. Cor. of one petal, superior, in fix deep, equal, ovate-oblong, spreading segments, permanent. Stam. Filaments six, very short, capillary; anthers oblong, shorter than the petals. Pfl. Germin inferior, turbine; ifyle thread-shaped, the length of the flaments; stigma three-eufl, blunflh. Peric. Capsule rather oblong, tapering at the base, crowned with the permanent corolla, and composed of three cells, not burrflng. Seeds numerous, roundish, 'with a lateral keel-like projection.' Brown.

Eff. Ch. Corolla superior, permanent, in fix deep equal segments. Capsule tapering at the base, without valves. Seeds numerous, with a lateral keel.

Obf. Mr. Brown, like Gartner, describes the capsule as not separating into valves, which is true of some species, but the whole have not yet, in his opinion, been sufficiently examined.

Undoubted species of Hypoxis are,

There are bulbous herbs, with numerous radical leaves of a lanceolate form, channelled, hairy or smooth. Stalks radical, more or less eorynhoce. Flowers resembling those of the English Orchis libicium, yellow within, green underneath.

Willdenow enumerates 15 species in all, some of which are suspected to be varieties.

H. juncea. Sm. Spicll. t. 16. brought by the late Mr. Frater from Carolina, is supposed to be a harrow natural-row-leaved variety of the coryph, the flanks of which are fingle-flowered.

HYPOZOMA, in Anatomy, a name given to such membranes as separate two cavities.

In this sense the mediaetalium is an hypozoma.

HYPPASUS of Metapontus, or Crotonia, in Biography, is enumerated among the disciples of Pythagoras, late in his life. Theon of Smyrna informs us, that Latus and Hypasus seeking celebrity, and in order to avoid the tediousness of calculation by the ratio of numbers, as Pythagoras found the proportions of intervals by means of hammers and strings, his two disciples discovered by means of different portions of water in two vales or grifls of equal size, and in unison with each other; that when one of them was half filled with water, leaving the other empty, the refult was the octave 2:1. Then filling one vase or grifls three parts full of water, and the other half full, they produced the proportion or confluence of the 5th or 3:2; and, lastly, four portions of water in one grifls, and three in the other, produced the fourth or 4:3. The fame proportions of confluences were still produced as in the Sylinx from reeds of different lengths, or by holes in the flute, or tibia.

This article has been infected by Padre Martini without telling us that he had proved it to be true by experiment.

HYPPASUS, according to Lucian, was an excellent musician, and the first man of his time for geometry, perspective, and astronomy. He was also a great architect. A description of the magnificent baths of his construction may be read in Lucian.

HYPARHION, in the Ancient Musical Instruments. The Lyrians, according to Pollux, invented a kind of flute called hypophonion, because its found resembled the acute neifing of a horfe.

The hypophonion was made of a fliick of laurel fcript of its bark and pith, and ferved thofe who had the care of horfes at pature as a kind of lure or horfe-call.

HYPPOMACHUS, in the Ancient Greek Music. An eminent performer on the flute, perceiving one day at a public exhibition, that one of his disciples of ordinary talents was violently applauded by the common people, fentenced him by a blow of his caxe; telling him that the greatest proof of his ignorance was the being applauded by the mob.

HYPPONAX was the inventor of iambic verse, according to Athenaeus, lib. 14.

HYPSA, in Ancient Geography, a river of Sicily, placed by Ptolemy between Heraclea and Agrigentum, and according to this geographer, discharging itself into the sea to the fourth of the latter city. It is now called Belice, which fce.

HYSEPSELE, an episcopal town of Egypt, W. of the Nile, in a nome of which it was the chief place, called the Hypselites nomos.

HYPSCLES, in Biography, an ancient mathematician who flourifled in the second century, under the reigns of Marcus Aurelius and Lucius Verus, was a native of Alexandria, and a disciple of Iulianus. He was author of a work entitled 'Artha, or five of Aetennomus,' which was publifhed at Paris by Mentelin, with the Optics of Heliodorus in 1657. He is supposed to be author of the 14th and 15th books of the 'Elements of Geometry,' which are commonly attributed to Euclid. Gen. Biog.

HYPSICRHYMNOS, in Ancient Geography, a town in the vicinity of Caucaus, faid by iEthelby, in his Prometheus, to have been peopled by Arabs.

HYPISOLO
HYPSILOGLOSSUS, in Anatomy, the name with biaugloglossus. See also Hyoglossus.

HYPSIOIDES, from δια διά, and οιδος, form, the name with hyoides; which see.

HYPSISTARI, HYPSISTARIANS, a genus, formed from the Greek ὑποστάριος, meaning a bottomless hole, in the Zoological History, a sect of heretics in the fourth century; thus called from the profession they made of worshipping the most High God.

The doctrine of the Hypsistarians was an assemblage of Paganism, Judaism, and Christianity. They adored the most High God with the Christians; but they also revered fire and lamps with the Heathens; and observed the Sabbath, and the distinction of clean and unclean things, with the Jews.

The Hypsistarian bore a near resemblance to the Euchites or Mysians.

HYPSOPHYLLUM, in Surgery, an ulcer under a cicatrix or eczema.

HYPSUS, in Ancient Geography, a town of the Peloponnesus, in Arcadia, name of Megalopolis.

HYRIS, H. B. Auct., a genus named by Jacquin from ζήλως, repugnans, because the limb of the corolla is turned, as it were, upon its back. Schreb. 388. Wildsp. Pl. v. 3. 84. Mart. Mill. Dict. v. 2. Jacq. Collect. v. 1. 121. Jaff. 449. Lamarec. Dict. v. 3. 184. Illustr. t. 507.

Gen. Cal. Calyx, Perianth turbinate, permanent, divided half way down into five, lanceolate, acute, generally equal, crest segments. Cor. of one petal, reflexed; tube funnel-shaped; throat dilated; limb spreading widely, repugnate, the upper lip, which is reflexed as to its situation, cut into three, lateral, ovate, acute segments, the middle one rounded, concave, obtuse; the lower lip (turned uppermost) is divided half way down into two, oval, flat, acute segments. Stam. Filaments four, awl-shaped, two shorter, authors twin, dependent. Pijg. German four-clefli, style thread-shaped; stigma bifid or simple. Prick none, the calyx protecting the four seeds.

Eif. Ch. Calyx five-toothed. Corolla ringent, reflexed, its upper lip bifid, lower one trifid, the middle segment formed like a little pincushion. Stamens declined.

1. H. verticillata. Wildl. n. 1. Jacq. C. R. v. 1. t. 113. "Flowers in whorls. Leaves lanceolate, toothed." — A native of Hifpaniola. It flowers in the months of Europe about November or December. This flower is about ten inches high, with one or two upright fluma, which are smooth, brownish-ash-coloured, round and woody; the younger branches square and herbaceous. Leaves opposite, on footstalks, lanceolate, acute, unequally serrated, smooth, from three to five inches long, finely odorous. Whorls on the younger branches, at each pair of leaves, sessile, level, flowered. Corolla in Ecballium, with the segments of the upper lip purplish. Calyx a little hispid at the back and at the edges of the segments. Anthers pale yellow.

2. H. capitata. Wildl. n. 2. Jacq. C. R. v. 1. t. 114. "Flowers in little stalked heads. Leaves ovate, toothed." — This is also found in Hifpaniola, flowering in December. Stein rather shrubby, about a yard in height, square, brown. Branches annual, subdivide, roughish. Leaves opposite, on footstalks, veined, unequally serrated, rather hairy on both sides, dark green; the lower ones wrinkled, about seven inches long. Flowers-fluxus bearing numerous white or bluish-coloured flowers collected together into a semi-globular head. The tube of the corolla is a little hairy on its outside, especially on the back of the head. Whole plant inodorous.

Vol. XVIII.
HYRCANIA, or Hyrcanus Campus, a country of Asia Minor.

HYRCANIA, a country of Asia, S. of Babylonia; inhabited by the Hyrcani, who, as well as the Saci and Cadians, occupied that district which lay between the Tigris and the Euphrates. These people were powerful enemies of the king of Assyria; and an alliance with them was sought for by Cyrus in his war against this prince. He formed of these people 2000 cavalry, and a very considerable body of infantry; and having dispossessed the Assyrians of their garrisons on the frontier of the country, Cyrus assigned them to his new allies. The Hyrcani, who inhabited Hyrcania, on the coast of the Caspian sea, were a ferocious people.

HYRGALE, a town of Asia, in Phrygia Salutaris; situated on a river towards the northern part of this province. The chief magistrates bore the title of Archon. The worship of Cybele was established in this city; but abandoned on the introduction of Christianity. Its bishop asisted at the council of Chalcedon, in 451.

HYRIA, a town built by the Cretans, who assumed the name of Japyges Meffapii. It was situated in the interior of the country between Tarentum and Brundisium. Strabo calls it Oria, and the Latins Uria. It is now Dria.

HYRYNSELMI, in Geography, a town of Sweden, in the government of Uleå; 34 miles N.E. of Uleå.

HYS, a town of the Arabian Irak, on the Euphrates; 120 miles S. of Bagdad.

HYSSOP, in Botany and Gardening. See Hyssopus.

HYSSOP, Common, Hyssopus officinalis, in the Materia Medica, is a native of Siberia, and the mountainous parts of Austria, and flowers from June till September. The hyssop mentioned in the Old Testament is not supposed to be this plant, which is neither the șof of the Hebrews, nor the șapso of the Greeks. It was first cultivated in England by Gerard in 1596, and is now extremely common in our gardens. The leaves of hyssop have an aromatic smell, and a bitterish, moderately warm taste. They give out their active matter both to water and rectified spirit; the watery infusions are of a brownish or greenish yellow, and the spirtuous tinctures of a blackish green colour. On infusing the latter, the remaining extract retains its flavour, is bitterish, and very warm, and discovers a penetrating pungency, resembling that of camphor. Water, distilled from the fresh herb, is found pretty strongly impregnated with its flavour.

HYR, HYS

HYR, HYS

places of its retreat a particular sub stance suppo sed by them to be deposited from the urine of this animal after long exposture to the air; and which they maintain to be a sovereign remedy in many disorders; the colour of this sub stance when dry is blackish, and the smell offensive in the extreme. When domesticated the Cape hyrax becomes a familiar and interesting animal, and one susceptible of attachment. If called by any name by which it is accustomed to be distingu ed, it replies in a short but sharp and piercing cry, and approaches those it knows in confidence. It dreads cold, and places itself close to the fire when it can conveniently. The disposition of this animal is remarkably timid. Those transported from the Cape into European climates have been known to subsist on bread, potatoes, fruits, and various other vegetables.

HYR CAN I, John, in Biography, high-priest and prince of the Jews, was the son of Simon Maccabeus. On the invasion of Judea by the Syrian governor in the year B.C. 139, he and his brother Judas led a body of troops, who entirely defeated the invaders. After his father's murder by his son-in-law, Ptolemy, he went to Jerusalem, where he was declared Simon's successor in the priesthood and fore rager. This was in the year 137. Antiochus Sidetes laid siege to Jerusalem, but was induced to grant a peace to the Jews upon condition of their dis mantling the city, and the payment of a large sum of money. Hyrcan afterwards made an alliance of friendship with Antiochus, and accompanied him in his war against Phraates, king of Parthia, in which he did much service, and after the death of Antiochus, he took advantage of the civil discontents prevailing in Syria, made himself master of several neighbouring towns, and entirely shook off all dependance on that crown. He afterwards became the aggressor, and made considerable conquests for his country, till at length he extended his dominion not only over Palestine, but also over the provinces of Samaria and Galilee, and the Jewish state appeared with greater lustre than under any of his predecessors since the captivity. He was zealous for his religion, and attached to the sect of Pharisees, but a quarrel with that haughty and powerful body embittered the latter part of his life. He died in the year 106, and was succeeded by Aristobulus.

HYR CAN II, high-priest and king of the Jews, was eldest son of Alexander Jan nas; but at the death of his father, his mother Alexandra took the reins of government, and allotted to him the succession of the priesthood. On her decease Hyrcan was declared king, but being of a quiet and unenterprising disposition, he was quickly dispossessed of his dignities, and reduced to a private station. He was afterwards persuaded by Antipater to accompany him to Arabia, in the vain hope of obtaining the alliance of king Aretas to restore him. The Romans, gained over by Aristobulus, the brother of Hyrcan, defeated Aretas, and the two brothers at length pleaded their cause in person before Pompey. In the year 63 B.C. Hyrcan was restored to his pontifical office with the title of prince, but he was de voted to royalty, and made tributary to Pompey. He lived several years under the protection of the Romans; and was very much favoured by Cæsar, but at length he fell into the hands of his nephew Antigonus, who cut off his ears, in order to incapacitate him for the priesthood. He was then carried into Parthisa, where he was well treated, till he complied with an invitation from Herod to return to Jerusalem, and resume the pontificate. His honours were of short duration, being beheaded by the tyrant when he was in the eighteenth year of his age. Josephus, Univer. Hist.

HYRCANIA, in Ancient Geography, a large country of Asia, situated to the south of the easter part of the Caspian sea, hence called the Hyrcanian sea. It had on the W. Medias, on the S. Parthisa, and on the E. Margiana. This country was mountainous, covered with forests, and inaccessible to cavalry. It was separated from Parthia by mount Coromene, according to Ptolemy the Maximus, S. of them the Chirind, and also the Avars, were situated towards the sea. Its towns were Barangea, Adraphi, Capea, Aberbina, Amanu-us, Sinica, Hyrcania the metropolis, Salce or Sacce, Amsura or Asmura, and Manfoca.

It is now well known that Timothoüs, the Neflorian pontiff, who had been raised to that dignity A.D. 778, converted to the Christian faith by the ministry of Subchal Jefu, whom he had consecrated bishop, first the Cola and Dailanites, by whom a part of Hyrcania was inhabited; and afterwards, by the labours of other missionaries, the rest of the nations, which had formed settlements in Hyrcania, Bactria, Margiana, and Sagdo. It is also certain, that Christanity enjoyed in these vast regions, notwithstanding the violent attacks of the Mahometans, to which it was sometimes exposed, the advantages of a firm and solid establishment for a long course of ages; while the bishops, by whose ministry it was propagated and supported, were all consecrated by the sole authority of the Neflorian pontiff.
An effluent oil is obtained from the distillation, which
rises to the surface, to the quantity of about an ounce from
six pounds of the leaves: this oil is very pungent, and in
smell exactly resembles the hyssop.

The stimulating quality of hyssop is ascribed to the quan-
tity of essential oil which it contains; and with a view to its
aromantic and stimulant effects, Bergius recommends it as an
emmenagogue and antihysterie; but it is chiefly employed
as a pectoral, and has been long thought an useful medicine
in humoral affections, coughs, and catarrhal affections: for
this purpose, an infusion of the leaves, sweetened with honey
or sugar, and drank as tea, is recommended by Lewis.

Hyssop is greatly commended in cafes of bruises from
falls, blows, &c. used externally by way of fomentations,
or only a little bundle of the plant feathed in
in a linen rag, and applied to the part. Ray gives an ac-
count from Mr. Boyle, of a violent contusion of the thigh,
from a kick of a horse, which was happily cured by this
herb, boiled and applied as a cataplasm. He tells us, the
violent pain was almost instantly removed, and the very mark
and blackness taken off in a few hours. It is also recom-
mended as a vermifuge by Rosenfels. Wood. Mat. Med.

Hyssop was commonly made ufe of, as we learn from the
scriptures, in purification. Thus God commanded the
Hebrews when they came out of Egypt, to take a bunch of
hyssop, to dip it in the blood of the passchal-lamb, and
sprinkle the lintel and two side-posts with it. (Exod. xii.
v. 22.) Sometimes a little wood was added to it of a scarlet
colour. So in the purification of lepers, a bunch, composed of
hyssop, the branches of cedar, and red wood, was
 dipped in water, mingled with the blood of a bird, and, with
this the leper was sprinkled. (Levit. xiv. v. 4.) David
also alludes to these ceremonial cleanings in his 51st Psalm,
v. 7th. "Purge me with hyssop, and I shall be clean."—
Cruden observes it is very probable that this plant grows to
a great height in Judea, since it is said in the Gofpel,
that the soldiers having filled a sponge with vinegar, they
put it upon a stick of hyssop and presented it to our Sa-
nior’s mouth, which was then upon the crofs.

Hyssop, Hedge, in Botany and the Mater Mecica.

See Gratiosa.

Hyssop, Mountain. See Thymbra.

HYSSOPIC ART, a name which Paracelsus gave to
chemistry, considered as the art which purifies metals, minerals,
&c. in allusion to that text in the Psalms, "Purge me
with hyssop, and I shall be clean."

HYSSOPUS, in Botany, generally taken for
Dysophyllum, a plant derived by from u,v, to rain, or to be
flowered on, and u,t, the tenacious, because the dust of this
plant, when dried and pulverized, was used in the Grecian
facrifices for sprinkling the head and eyes, as the Catholics
now use holy water for the purpose of crossing themselves,
and this operation was supposed to cleanse the impurities
of those over whom hyssop was sprinkled. Professor Martyn
more justly deduces the word from the Hebrew, Ejfub. Linn.
Tournef. t. 95. Lamarck Dict. v. 3. 185. Illutr. t. 502.
—Clasf and order, Didymia Gymnophanis. Nat. Ord. Ver-
ticatia, Linn. 1807. Juff.

Gen. Ch. Cal. Perianth of one leaf, cylindrical, oblong,
frívated, acutely five-toothed, permanent. Cor. of one petal,
regular; tube cylindrical, longer as the calyx; throat incrived;
upper lip straight, flat, short, roundish, emarginate; lower lip divided into three segments, the lateral
ones shorter and obtuse; the middle one crenate, obtuse,
acute, with distant lobes. Stam. Filaments four, erect, longer
than the corolla, dilatant; the two upper ones shorter, but the
two longer ones nearer to the lower lip; anthers simple.
Pist. Gernan four-cleft; style thread-shaped, under the
upper lip, and of the same length; stigma bifid. Peric.
none; the calyx containing the seeds, which are four in
number, and fobovate.

Eff. Ch. Corolla with a small middle crenate segment
in its lower lip. Stamens straight, dilatant.

Jacq. Afrur. 1. 254. "Spikes all leaning in the same di-
rection. Leaves lanceolate."— A native of the south of
Europe, flowering from June to September. Red woody,
half an inch thick. Stem about 18 inches high, at first
square, then round. Leaves fiddle, the lower ones in pairs,
narrow, smooth, entire, like those of lavender, but shorter.

Flowers in whorls, from the bogs of the leaves, continued
into a spike, of a blue colour, but varying to red and white.
The whole plant has a strong aromatic scent, and was cul-
tivated in this country by Gerard in the year 1596.

Jacq. Hort. Vind. v. 2. t. 181. —"Flowers reupleinate,
lower stems shorter than the corolla. Leaves cordate."—
Native of Siberia, flowering in August and September.

Roset perennial, fibrous, sending out many square stalks, which
divide into branches. Leaves heart-shaped, rough, pale
on the under side. Clusters of four or five violet flowers are
produced at each joint of the stem. The tube of the corolla
is longer than the calyx.

796. Jacq. Hort. Vind. v. 1. t. 69.— Stem sharply quad-
angular. Flowers in close clusters. Leaves ovate.

Native of Virginia and Canada, flowering from August to October.

—Roset perennial. Stem erect, about four feet high. Leaves
obliquely coriaceous, or ovate, serrated, acute, on short foot-
stalks. Flowers yellow, in thick close spikes four or five
inches long; upper lip of the corolla divided into two roundish
segments. Seeds brown.

There is a variety of this species with purple stalks and
flowers, the leaves on longer footstalks, and the spikes of
flowers denfer, but Willdenow has made a new specific of it,
we presume, under the name of H. Scrophularifolia. Vide

HYSSOPUS, in Gardening, affords a plant of the low
under-hraubbey kind; of which the species cultivated
is the common hyssop (H. officinalis).

There are several varieties, as the blue-flowered, the white-
flowered, the red-flowered, the long-spiked, with deep blue
flowers, the curved-leaved, and the fringed-leaved.

Method of Culture.—This is a kind of plant which is ca-
parable of being raised by means of seeds, cuttings, and
flips.

The seeds should be sown in a bed or border of light
mould, prepared for the purpose, in the spring season, being
well raked in. When the plants appear, they should be
thinned where they stand too close, and as soon as they are
three or four inches in height, be planted out in the
places where they are to grow. In the forming of edgings
of this plant, the seeds may be deposited in drills run along
the edges of the borders, &c. where they are to grow,
being covered in about half an inch in depth.

In the two latter modes, some of the more robust fide-
flowers should be cut or clipped off, and planted in a shady
border, or other place, in the latter part of the summer,
at the distance of five or six inches from each other, water
being immediately given, and occasionally repeated. The
plants should take root, when in the autumn they may be fe-
t out where they are to grow.
HYSTERIA, a term used by some of the old writers in medicine to express the febrility.

HYSTERALGIA, in Medicine, from the Greek ὑστερός, signifying the womb or uterus, and ὀργας, pain, a term used by the nofologist to denote all the slow painful diforders of that organ.

Sauvages describes fifteen species of hyferialgia, diftinguishing them by the various circumftances by which the pain is excited. Thus he includes, under this genus, the pains arising from prolapsus of the uterus (Spec. 1. H. ab hyfterechos); from hema of the fame vicinus (2. H. ab hyfteroe); from dyfamenorrhoea, or painful menstruation (3. H. a menologia); from cancer of the uterus (4. H. cancras); from ulceration and feirius (5. H. ulceras, feirius); from pruritus in the uterus (7. H. pruigina); from a fomy fubftance in it (8. H. ab effe). See Hody, in Philof. Tranfaet. vol. vi. p. 191.1) from intermittent fever (9. H. febrifera, Morton, Pyretologia, p. 92.) from hyfterical affections (10. H. vaporara); from abfolute fuccedaneity to inflammation of the uterus (11. H. ex abfolla. See Hysteritus); from the gradual dilatation of the uterus in pregnancy (12. H. impregnatarum) from fuppreflion of the milk (13. H. laleta); from the natural contractions of the uterus after delivery, during the discharge of the lochia, commonly called after-pains (14. H. lochia); from a fuppered tranflation of the milk to the hypogastric region (15. H. ab hypargnoye); and, laftly, from calculous conceptions formed in the uterus (16. H. calcolafa). See his Nofic Meth. Clafs vii. Ord. 4.

It will be observed, that none of these varieties of hyferialgia, fuch as those connected with the enlargement of the gravid uterus (fp. 12) and the after-pains (fp. 14), can barely be considered as difafe, unlefs they occur in an uncommon degree of fervency; while, on the other hand, fome of them are extremely rare; as the cafe described by Hody (fp. 8.1), and the variety occasioned by the prevalence of calculi. The frift and second fpecies, depending upon prolapsus of the vagina and hermis, can only be relieved by mechanical means, by which the uterus may be reftored in its natural ftuation. (See Prolapetus Uteri, and Hysterocele.) Ulceration and cancer of the womb confitute the moft painful and difturbing difafe to which the female frame is fubjeét, and will be treated of under their proper heads. See Womb.

But, in addition to thefe infirmities of hyferialgia, there are cafes in which pain, referred to the uterus and its appendages, is a leading fymptom, and cannot be ascribed exactly to any of the cafes above-mentioned. Such pains fometimes come on after a few weeks after delivery in marjred women, and are ofteft dated from the lat child-birth. They are moft commonly accompanied by fome irregularity in the menfeurial discharge, generally by an increafe of it, or by alternations of a bloody, with a thinner, lefs coloured, and offensive evacuation. The symptoms vary a little in different cafes, apparently according as the uterus itself, or its particular appendages are difordered. In general the patient complains of pains in the loins, extending round the margin of the pelvis to the groin, on one or both fides, and shooting down the thigh to the knee, or, in more severe cafes, even to the foot. Sometimes the pain is more ftrictly referred to the uterus itself, or its neck, and the loins are fearcly affeded; and fometimes it is fixed, in one fide, above the ilium, as if rooted in the ovarian. In one cafe we have seen the difafe confined apparently to the ovarian and ligaments of one fide, in which there was great fomew of the part, where the round ligament paffes to the pubes. The flomach is frequently difordered by (fypathy), and the patient complains of nausea, flatulence, and other fymptoms of indigation; and occasionally fame degree of febrile action attends these complaints.

Thfe forms of hyfphericalgia are by no means unfrequent, efpecially among the poor; and they difeafe no fome degree of chronic inflammation, and difeased fcction in the uterus, confluent on the irritations of child-birth, or produced by caufes suddenly interrupting or deranging the lochial and menfeurial efcurions. Sometimes it is probable that they are merely the feigns of inicipient febrilus.

There are no medicines which operate particularly upon the uterus. When there is feercly a few cafes connected with hyfessional, laxatives and diathernome are the moft useful medicines, the pain being at the fame time foothered by conium, opium, linum, or other anodynes. The tincture of the hop, or humulus lupulus of Linnaeus, has frequently appeared to afford fome in thefe cafes, when the other narcotics had failecd; but perhaps this observation is applicable to any medicine of this clafs. When the hyfphericalgia is connected with great weakness and lownes of spirits, and a confiderable leucorrhoea, cordials and tonics, combined with the anodynes juft mentioned, must be adminiftered. In the cafe attended with pain and forene fy the course of the round ligament, the application of leeches to the groin, and the ufe of saltn laxative, afforded relief. In all these cafes cold, or abfolute from all motion, efpecially from walking, feem to be beneficial; although perhaps negatively, by allowing the vefles of the part to recover their natural actions, which the erect posture and the irritation of walking tend to prevent. See Edin. Med. and Surg. Journal, vol. iv. p. 244.

In the volume of the Journal, juft quoted, a cafe of hyfervalgia is related, which continued, without one day's ceffation, for twenty-fix years, yet no derangement in the structure of the uterus, sufficiently to account for it, was discovered after death. See p. 168.

HYSTERIA, HYSTERICS, or HYSTERICAL AFFECTION, from ὑστερος, the uterus, or σωμα, implies literally the uterus diseafe; it denotes a flate of constitution, in which a variety of fpiritual, modic, convulsive, and painful affections occur, together with extreme variability of the fpirits, and a frequent fene of fuffocation, from a ball rising from the abdomen to the throat, which has been called the globus hhyfericus, and confidered by fome as the effential characteristic of the difafe.

Other appellation have been given to the difafe, with refence to its origin from the womb, especially to the convulsive paroxysms, or hyfpherical fits, which have been called fuffocation of the womb, affecfion uteri, fies of the wother, &c. The appellation of vapours has alfo been applied to this difafe in females, as well as to the hypochondraifis in men; and from a fimilar notion, that it is occafioned by vapours, ascending from the uteruses, and affecting the brain, lungs,
HYSTERIA.

...as vapours arising from the stomach, liver and spleen, were supposed to give rise to hypochondriasis. All medical writers have admitted the difficulty of describing, in a concise manner, the various forms of this disorder, which exhibits such a number of phenomena, which rapidly appear and change, that it imitates almost every disease of the nervous system, and even several of the more fixed and organic diseases. "Diss me dicere," says Sydenham, "nulla omnia, quae afflicet hyberonica graviter, symptoma enumerare velit; tamen diversa ad invicem contrae specie variantis, quam nec Proetus fuit ineptus, nec coloratus spectatui chameleon." (Differtatio Epitola- liaris ad Gr. Cole.) The most complete form of hysteria, however, is seen in the paroxysms, or fits, which occur at various periods, without any regularity. These are commonly preceded by a sense of latitude, coldness of the feet, and a copious discharge of pale limpid urine: often by pain in the head, loins, or stomach; which latter organ, as the fits commence, is sometimes affected with vomiting. The paroxysms commonly begin by some pain and fulness felt in the left side of the belly. From this a ball seems to move, with a grumbling noise into the other parts of the belly; and, making as it were various convolutions; there, seems to move into the stomach, and more distinctly still rises up to the top of the gullet, where it remains for some time, and by its pressure upon the larynx gives a sense of suffocation. There is occasionally much difficulty of breathing, and a palpitation of the heart at the onset. By the time the disease has proceeded thus far, the patient is affected with a stupor and insensibility, while at the same time the body is agitated with various convolutions: the trunk of the body is writhed to and fro, and the limbs are variously agitated; commonly the convulsive motion of one arm and hand, is that of beating with the closed fist upon the breast very violently and repeatedly. The whole of the belly, and particularly the navel, is often drawn strongly inwards; sometimes there is a violent working, or alternate rising and falling of the belly, attended with considerable noise. The "phintur ani," during the fit, is sometimes so forcibly contract'd as not to admit a small glass-pipe, and there is at the same time an entire suppression of urine. This state continues for some time, with some remissions and renewals of the convulsive motions; but they at length cease, leaving the patient in a stupid and feemingly sleepless state. More or less suddenly, and frequently with repeated sighing and sobbing, together with a mumuring noise in the belly, the patient returns to the exercise of sense and motion, but generally without any recollection of the several circumstances that had taken place during the fit.

Such fits are very liable to recur from time to time, and during the intervals the patients are subject to involuntary motions, to fits of laughing and crying, with sudden tranisitions from one to the other; while sometimes false perceptions and some degree of delirium also occur, as well as all the various incoherencies of the disea; to which we alluded above. The preceding account is that of the most common form of the hyberonica paroxysm; but this is considerably varied in different persons, and even in the same person at different times. It differs chiefly by having more or fewer of the circumstances above-mentioned, by the greater or less degree of violence of these, and by the different duration of the whole fit. See Cullen, Phil. Lines, par. 1514, et seq.

Sydenham has enumerated the principal varieties of form, which the irregular hysterica, as it has been termed, assumes; or, to use perhaps a more correct expression, the principal disorders of the function, which take place in the intervals of the paroxysms, or occur where the paroxysms do not appear. "The disease," he says, "is not more remarkable for its frequency, than for the numerous forms under which it appears, resembling most of the distempers wherewith mankind are afflicted. For in whatever part of the body it be seated, it immediately produces such symptoms as are peculiar to that part; so that unless the physician be a person of judgment and penetration, he will be mistaken, and suppose such symptoms to arise from some essential disease of this or that particular organ, and not from the hysterica -ympota." (Loc. cit.) Dr. Ferrar, in his chapter on the "conversion of diseases," has remarked that the conversions of hysteria are very common sources of error to young practitioners, and sometimes deceive even the most experienced. "Whoever would present us with a good book," he says, on the fallacy of symptoms, which is greatly wanted, must be completely master of this unaccountable disease." Ferrar, Med. Histories and Reflections, vol. ii. See also Conversion of Diseases, where the substance of that ingenious dissertation will be found.

"When the hysterical disposition is set in motion, the same author observes, it is not uncommon to find many of the different viceera attacked by it in turns, and the difeases peculiar to each counterfeited with much exactness. I have seen symptoms of paralysis, jaundice, palpitation, and nephritis, that succeeded each other rapidly in the same patient, while some of the characteristic marks of hysteria have been discernible, and where the unity of the disease was proved, by the disappearance of all menacing affections, on the approach of regular fits. In one case, the bowels were attacked, and the symptoms of interitus were so precisely imitated, as to give much alarm for the patient's safety. I supposed the real nature of the diffuse, from observing that the pulse was soft and full, that the evacuations were natural, and that her spirits were agitated, even to involuntary emotions, by flight cauæs. This case terminated successfully, on the accission of clear hysteric symptoms. Several years ago, I attended an elderly lady, for a complaint which seemed to vibrate between apoplexy and palsy; after lying for several weeks in a state which afforded little hope of amendment, she was affected with involuntary foasting and weeping; the complaints in her head and limbs were converted into hysterical convulsions, and the recovered completely.

"It is very common to meet with syncope, or palpitations of the heart and great vessels, accompanied with a soporific depression, or extreme dejection of strength and spirits, and converted, after deep sighing or discharge of tears, into the hysterical paroxysm. In these cases, the pulse is sometimes full and regular during the most alarming appearance of fainking, and sometimes variable to such a degree, as to exclude all conjecture, excepting that of an hysterical origin.

"I have met with several cases of hysterical hæmoptœ, in which the quantity of blood evacuated was very considerable; six or eight ounces were sometimes spit up daily, for a fortnight or three weeks successively. Moil of the usual symptoms attended, which denote danger in this complaint, when it arises from other causes; but the equal moderate state of the pulse, and the appearance of some degree of globus hysterica, seemed to determine the nature of the complaint; a conversion accordingly soon took place to the ordinary hysterical paroxysm, and no bad confenquenœ followed. The hæmorrhage from the lungs.

"In all similar instances, the supernumerous hysteric paroxysm puts a favourable termination to the irregular appearances." Loc. cit.

Sydenham's account of these irregularities differs, in some respects, from the one just detailed; especially inasmuch as he.
HYSTERIA.

he does not generally notice the solution of the local complaint by the occurrence of the regular hysterical paroxysm, which he mentions only as one of the forms which the disease assumes. He seems to consider the copious discharge of limpid urine, as the chief characteristic of the hysterical attacks, which counterfeit other diseases; (Opera Unius, Edit. Lugd. Bat. 1726, p. 392. 394. 572. Wallis's Translat. p. 111. 114. and 599, vol. ii.) but he looks upon this symptom as belonging in common to hysteria in women, and to hypochondriasis in men.

Among the diseases which he has observed to be counterfeited by hysteria, are apoplexy, when it attacks the head, which terminates in hemiplegia, and is chiefly seen in lying-in women, after difficult parturition, attended with great hemorrhage; the edema hystericus, or acute pain in one small spot in the head, which is often accompanied by vomiting, and palpitation of the heart; these are most frequent in delicate and chlorotic girls; pain in the abdomen, colic, with porceaneous vomiting, resembling the ileus passion, terminating in jaundice, and always accompanied by great debility; chiefly attacking women of lax fibre, who have suffered severe labours from large children; pains in the kidneys and bladder, like fits of the stone, with suppression of urine; occurring in women much debilitated by previous hysterical fits, and in a bad state of health; who are liable to long-continued vomiting and diarrhoea, without pain, discharging green bile. He likewise remarks, that the disease is liable to attack the external parts and mucous flesh, sometimes causing pain, sometimes swelling, in the throat, shoulders, hands, thighs, and legs, more especially in the last; which swelling, however, is to be distinguished from edema, by being greatest in a morning, by leaving no pit after pressure with the finger, and by commonly affecting only one leg; though its external appearance much resembles that of edema. But the most severe of these pains, is that which affects the back. He adds, that these pains have this circumstance in common, that they all leave the parts extremely sore and tender, as if they had been febrically beaten, so that they cannot bear the touch for some time; and that these pains and other symptoms are all preceded by a death-like coldness of the external parts. Diff. Epileptics.

To conclude, the regular hysterical paroxysm sometimes alternates with the cataleptic fits, in which the patient remains fixed in one inflexible position (see Catalepsy); sometimes with a loss of voice; with carus; and with various states of mental derangement, as nymphomania, fatuity, &c.

Causes of Hysteria.—The predisposing cause of this disease appears to consist chiefly in a certain mobility of the nervous system, which is almost peculiar to the female constitution, the "varium et mutabile, femina," more especially to females of a fangnique temperament, and of a plethoric and irritable habit. The disease, therefore, is very rarely seen in the male sex, and never in the same exquisite degree in which it occurs in women. In the latter, it appears most generally from the age of puberty to that of thirty-five or forty years; very seldom before the first or after the last of those periods; but at all ages, the time at which it most readily occurs is that of the menstrual period, and it is often obviously connected with some irregularity or deficiency in the uterine functions; as with suppressed or difficult menstruation, pain in the uterus, &c. It affects barren women, more than those who are breeding, and therefore frequently young widows. It occurs especially in those females who are liable to nymphomania; and the noologically have properly enough marked one of the varieties of this disease by the title of hysteria bibidosa. It is more frequent in cold than in hot climates.

The exciting cause of hysteria, which readily operate on a constitution pre-disposed to the complaint, are especially all violent passions, and every considerable emotion of the mind, particularly those brought on by surprie. Some females, liable to this disease, acquire such a degree of sensibility, as to be strongly affected by every impression, however slight, that comes upon them suddenly and by fright; even by disagreeable odours, lights, &c. An indolent life and a luxurious manner of living tend both to augment the pre-disposition to the disease, and to call it into action. Any irritation, especially in the alimentary canal, or in the uterus, will excite hysteria; whence it often accompanies a state of inanition, or emptiness of the stomach from long fasting (Sydenham, loc. cit.); the use of a strong emetic or purgative (idem.); painful menstruation; and an immediate discharge of the menses, either in child-bed, or at other times. It is also occasionally excited by a prolapsus of the uterus, though more rarely; and it has been said to follow the repression or metamorphosis of chronic cutaneous eruptions, intermittent fevers, and other acute diseases.

As to the proximate cause of the disease, it may be remarked, that its paroxysms appear to begin by a convulsive and iatrogenic affection of the alimentary canal, which afterwards influences the brain and a great part of the nervous system. But, as Dr. Cullen observes, "although the disease appears to begin in the alimentary canal, yet the connection which the paroxysms do often have with the menstrual flux, and with the diseases that depend on the state of the genitals, shows that physicians have at all times judged rightly in considering this disease as an affection of the uterus and other parts of the genital system." Par. 1520.

He concludes himself, however, unable to explain in what manner the uterus and the ovaria are affected in the disease; how the affection of these is communicated with particular circumstances to the alimentary canal; or how the affection of this part, rising upwards, affects the brain, so as to occasion the particular convulsions which take place. To say that there is a great sympathy between the uterine and digestive organs, is but to express the fact in other terms; and with this general expression we must be content at present.

Sydenham refers all the phenomena to the irregular motions of the animal spirits; which is a still more hypothetical expression of the fact, because the very existence of such spirits is a mere assumption, which a better investigation has rejected as altogether unfounded. He denies that the disease is to be ascribed "to the acent of malignant vapours from the corrupted semen or menstrual blood in the uterus to the parts affected, as some authors have asserted; or, as others affirm, to a latent depravity of the juices, or a collection of acid humours." And his reason is very conclusive against the humoral pathology: "For," he says, "that the cause of the disease does not lie concealed in any morbid matter, appears evident from this single instance. If a slender weak woman, otherwise usually healthy, happens, by mistake, to be debilitated and exhausted by a strong vomit or purgative, she will be infallibly feiz'd with some one of the concomitant symptoms of this disease; which would, by these means, rather have been carried off, than occasioned, if the cause of it had been any present humour. The same may be said of too great lusts of blood, whether it be taken away by bleeding, flows immediately after delivery, or be diminished by inanition and too long abstinence from meat; all which would rather be preventive than productive of hysterical diseases, if the cause of their confused in
HYSTERIA.

fome kind of morbid matter; whereas, on the contrary, they are never certainly occasioned than by these evacuations." Nevertheless, Sydenham was unable to banish completely his prejudices in favour of the humoral pathology, although refuting it thus satisfactorily; and therefore, he maintains that "the irregular motion of the spirits generates pathrid humour in the body;" and that these corrupt juices, collected in the blood, are sent to various organs, producing chlosis, and other cachectic diseases. Loc. cit.

It would be quite superfluous to enter into any discussion respecting the absurd notions of the ancients, who attributed the disease either to the aefent of vapours from the uterus, producing the sense of suffocation and convulsions, or to the aefent of the uterus itself, which was supposed to roam about the abdomen at times, and, by pressing the diaphragm upwards, to give rise to the symptoms. The latter opinion seems to have been held both by the philosophers and physicians; for Hippocrates (de Natura Mulierum) and Plato (Timæus) have expressed the same notion; the latter comparing the uterus to an animal, deprived of impregnation, and wandering through the whole body. Galen's knowledge of anatomy enabled him to refute these absurdities (de locis aërent. cap. 5); and therefore the notion of rising vapours was adopted, and it continued to be espoused for a considerable period after the restoration of learning. For a statement of the arguments, the reader may consult Semnert. Praet. lib. i. feo. 1. cap. 14. and lib. iv. part 2. feo. 3. cap. 4. the works of Fernel, &c.

Of the Diagnosis.—The hysteric paroxysm scarcely resembles any other affection of the body, except occasion- ally the paroxysms of epilepsy; but in epilepsy, the convulsive motions are generally much more violent, and the insensibility more complete; there is foaming at the mouth, and a state of coma or profound deep follows the fit; on the contrary, there is no globus rising into the throat, no agitation of the abdomen, no screaming, laughing, or crying, nor any copious discharge of limpid urine, as is common in the commencement of the hysteric fit.

The disease in general has been considered by many physicians as the same with hypochondriasis, the latter term being appropriated to it, when occurring in the male sex, and hystera when it is found in the female. But this seems to be improper, if the symptoms of the two diseases be accurately examined. They may have, indeed, some symptoms in common; but for the most part they differ widely. Spasmodic affections occur in both; but they are generally local, confined to particular parts, and much less severe in hypochondriasis, as well as much less frequent than in hysterica. Indigestion occasionally afflicts hysterical patients; but they are often entirely free from it, which never happens in hypochondriasis. But the diseases are still more certainly distinguished by the temperament which they usually attack, and by the time of life at which they appear to be most exquisitely formed: youth and a fanguine temperament being most liable to hysteria, while the middle or advanced periods of life, and a melancholic temperament, are peculiarly favourable to hypochondriasis. Nor are they limited to the respective sexes; for the male sex, when youth and the fanguine temperament, exquisitely marked, concur, is not absolutely free from the attacks of hysteria; and influences of hypochondriasis in the female sex, of the opposite age and temperament, are very common.

With respect to the irregular forms of hysteria, under which it resembles many other diseases, we have already anticipated the means of forming a diagnosis. Dr. Ferriar considers the supposition of the regular paroxysm as the principal source of discrimination; but as the disease is generally removed by this occurrence, it is desirable to detect the nature of those irregular affections at an earlier period. Besides the copious discharge of limpid urine, which Sydenham considered as the pathognomonic symptom of hysterical complaints, the same accurate observer deemed the state of the mind a valuable index of their presence; and it is obvious, from the observations above quoted from Dr. Ferriar, that he also attended to this point, and to the state of the pulse. As the most frequent exciting causes of hysteric fits are some sudden and strong emotions of the mind, whenever Sydenham was consulted by women concerning any particular disorder, which could not be accounted for on the ordinary principles of investigating diseases, he always inquired whether they were not chiefly attacked with it after fretting or any disturbance of mind; and if they acknowledged this, he concluded that the disorder was of the hysterical class, especially when the other diagnostic, copious pale urine, at the same time occurred. Epip. ad Dom. Cole.

Although the paroxysm of hysteria is extremely alarming to the inexperienced observer, it is scarcely ever fatal in its own form, unless when it is induced by some very violent cause; and the disorder generally disappears in the decline of life. Inflatures have occurred, indeed, in which it has continued to harass a patient from the commencement to the cessation of the catamennial discharge, and then ceased.

Of the Cure.—In the treatment of hysteria, as in many other diseases, considerable deliberation will be required in the application of remedies, which must be varied according to the form or degree of the complaint, to the temperament, habit of body, and condition in life, of the patient, and to the nature of the causes exciting it. Although that peculiar mobility of the nervous system, on which the disorder chiefly depends, is most frequently connected with a phlegmotic habit, and a purely fanguine temperament; yet this is by no means universal; for it is often observed in habits the reverse of phlegmatic, in which a considerable degree of debility, and a pale and phlegmatic temperament prevail. In ascribing the convulsive paroxysms of hysteria to a local phlegma or turbulence of blood in the uterus, from the analogy of epilepsy and althma, which he refers to a turbulence of blood in the vessels of the brain and of the lungs respectively, Dr. Cullen has obviously hit upon a false analogy, which will not bear him out in the explanation. For in the epilepsy and althma, the peculiar functions of the brain and of the lungs are disordered by phlethora of these organs; the functions of senes and motion, in the one case, and of respiration in the other, are almost exclusively deranged. But in hysteria, if the analogy were correct, the uterine functions should be alone or principally disordered; whereas the functions of the brain, the lungs, and the alimentary canal, are chiefly deranged, to which the supposed phlethora does not extend. See Cullen, First Lines, par. 1523.

Whatever notion be adopted as to the pathology of the disease, the curative indications seem to resolve themselves into two; namely, first, in the paroxysm, to check its violence; and, secondly, in the interval, to endeavour to lefien or remove the predisposing and exciting causes.

The first indication will be fulfilled by different means, according to the state of the patient's habit. If she is of a robust and phlegmatic constitution, blood-letting is the most effectual antiphalmodic that can be employed; and when the convulsions are severe, or long continued, with a flushing or fulness of the vessels of the face and external parts, it is the only antiphalmodic that can be administered with safety.
HYSTERIA.

At the same time, the turgescence and activity of the blood-vessels, and the consequent over-irritation of the nervous system, may be diminished by the application of cold to the head and abdomen, or to the body in general. The use of nauseating emetics has also been recommended for this purpose. Where the pletora is not so considerable as to warrant general blood-letting, cupping from the neck, or from any part in pain, may be substituted.

But in those habits, which exhibit no marks of pletora or of considerable strength, evacuations of blood, so far from being beneficial, are extremely detrimental, and are absolutely enumerated among the causes which induce the disease. In such conditions, the hysterical paroxysm is to be diminished or cut short by stimulant and antispasmodic medicines. Of these, opium, in its various preparations, is one of the most effectual; and its efficacy is considerably aided by a combination with the more diffusible stimulants, especially with aether and ammonia, or the volatile alkali. It is most commonly not difficult to force the patient to swallow twenty or thirty drops of sulphuric acid and of tincture of opium, in any liquid, at the commencement or during the continuance of the fit; and this is frequently followed by a speedy cessation of the spasmodic motions.

Various other stimulant medicines, especially those of strong and pungent odour, may be administered with good effect under the same circumstances; such are the preparations of valerian, musk, cau tor, camphor, asafoetida, oil of amber, oleum animale, &c. At the same time, any strong impression made upon the nervous system will frequently arrest the progress of the paroxysm; as the application of any strong-smelling substance to the nostrils, such as burning feathers, and volatile salts. The stimulus of heat may likewise be referred to for the relief of the paroxysm, when it is obstinate; and it may be applied to the whole body, by means of the warm bath; or to the lower extremities, in the way of pediluvium.

After the paroxysm is over, the means for fulfilling the second indication must be adopted, in order to prevent relapses: and as the principal predisposing cause and the leading feature of the hysterical habit, (the great mobility of the nervous system,) is connected with the opposite conditions of pletora and of inanition or debility, the first object will be to correct this predisposition, by the means adapted to the removal of the one or the other of these conditions respectively. In subdued and pletoric habits, the adherence to a moderate systole of living, to a light and spare diet, chiefly of vegetable matters, or weak animal broths, which may be taken in sufficient quantity to fill the stomach, and relieve the sensation of inanition, without affording a copious nutriment, must be strongly recommended. The use of strong cathartics for this purpose is deprecated by Sydenham; because the irritation of these medicines, and the sudden depletion which they occasion, when draughts, are liable to excite the paroxysms, in the mobile constitution of hysterical persons, and thus to produce the evil which it is the object of medicine to prevent. With a view to reduce the strength and fulness of the habit, the constant repetition of hydragogue purgatives is rarely not advisable; but for other purposes they are requisite, and shall be mentioned presently. The gradual ablation of nutriment is the safest method of reducing the pletoric condition, especially when combined with regular exercise. In the opposite state of constitution, in thin spare habits, the opposite method of replenishing the system by nutritious and full diet will necessarily be referred to, attending at the same time to the use of exercise. Sydenham observes that thin and bilious habits often derive the most beneficial benefit from a diet of milk, and
HYS

recommends an infusion of gentian, angelica, wormwood, centuary, orange-peel, and other bitters, in canary, to be taken in the quantity of a few spoonsfuls three times a day.

"But," the fame intelligent physician remarks, "the best thing I have ever found for strengthening and cheering the spirits, is riding on horse-back some hours almost every day." This exercise, indeed, appears to have been considered by Sydenham as a panacea in almost all chronic disorders; and, although confirmed confection may not yield to it so readily as his observations might lead us to expect, we are persuaded, that in all diseases, in which the alimentary and chylopoetic visceræ are chiefly disordered, this mode of exercise, readily persevered in, affords the most certain relief.

In attempting to restore the general strength, and to lessen the irritability of the nervous system, all those remedies, which are now well understood as being conducive to health, should be employed with regularity and perseverance. The forms of exercise, as well as the quantity of it, should be proportioned to the strength of the patient, and increased as the increasing strength renders it capable of being taken with flight fatigue. The clothing should also be regulated, with attention to the varying conditions of the atmosphere; and especially with care, that in chilly weather, the deviations from the mean may be always on the side of warmth; the attempts to harden the constitution, in habits extremely delicate and irritable, being as pernicious as they are absurd in principle. All anxieties and considerable emotions of the mind should be avoided, as far as possible, and the causes of them removed. And there are circumstances at times, which render it advisable to change the sexual condition of the patient, by marriage; by which the mental state in some cases may be probably relieved, and the uterus, being called upon to perform its natural functions, may likewise be restored to a more healthy condition.

From what has been said above, in regard to the deceptive forms of the irregular hysteria, when it mimics, as it were, the various organic diseases, according to the organ in which it takes its seat, we by no means wish to mislead the inexperienced into a belief that these organs are not often seriously affected, and that active remedies are not often to be applied to them in such disorders. On the contrary, Sydenham has mentioned the hysterical apoplexy as being sometimes fatal. All that is to be understood by calling these local organic attacks hysterical, is, that they occur in a constitution, in which either imperfect paroxysms of hysteria, or the great nervous mobility and variable spirit of the hysterical habit appear, in such cases the symptoms are to be considered as much less formidable than those of ordinary organic disease, and as likely to yield more readily to remedies, which therefore require to be used with less activity and vigour, and to be repeated with more caution. Whenever the individual organs and their functions are greatly disordered, it is the duty of the physician not to omit the remedies which experience has shown to be effectual in restoring them to health in other cases; watching, at the same time, the various concomitant appearances which may indicate the peculiar state of the habit, and may lead him to discriminate the counter-indications. Such discrimination, however, is not peculiar to the treatment of hysteria; it is in all diseases requisite, and the possession and exercise of it constitute the principal characteristic of an experienced physician.

Before we conclude, we must observe, that the apprehensions which Sydenham and many other physicians have entertained, relative to the danger of using purgatives freely in hysteria, appear to have been carried to a degree far beyond what unprejudiced observation would lead us. In this, as in many other diseases in which the alimentary canal is much deranged, a free purgation is not only safe, but most beneficial; and a considerable discharge of dark, offensive, and unnatural feces is often thus procured. Dr. Hamilton affirms, that he has adopted this practice with great success, calling in at the same time the aid of radish and tonic medicines, which, however, he considers as merely subsidiary. At all events, though Dr. Hamilton may have kept one indication too exclusively in view, yet the lesion which he has taught us, to unload the bowels in all these nervous cases, is doubtless extremely important. See his Obs. on the Utility of Purgative Med. 2d edit. ch. viii.

Hystericus Lapic. in Natural History, a name given to an American stone, called also lapis utrinus, supposed to be famous for its virtues against disorders of the womb, externally applied. It is black, and capable of a fine polish.

Hystericus Clavus. See Clavus.

Hysteritus, in Medicine, from υπάτ. which with the termination -itis, used to denote inflammation, signifies inflammation of the womb. Sauvages, and some other writers, have employed the term Hysteritis, from υπάτ., also signifying the womb or uterus, to denote the same disease.

The uterus is obviously liable to suffer inflammation, like the other visceræ of the body, from the common causes of inflammatory disease. In the unimpregnated state, however, it is less frequently attacked by this disorder than most of the neighbouring organs; and, indeed, if ever, is thus affected, except about the periods when its vessels are in a state of increased action, in consequence of the occurrence of the menstrual discharge. At these periods, when not only the uterine fyllem, but the constitution in general, undergoes a flight creethm, or tendency to febrile excitement, sudden exposure to cold, violent exercise, great heats, or very high feeding, occasionally bring on inflammation in the womb; more especially in females of plethoric habit, and strong fibre, who are accustomed to a fyllem of diet above the rules of just temperance. Where the uterus has become subject to inflammation in this way, it appears often to become unfit for the office of conception, and leaves the patient childless.

The most frequent cause of inflammation of the womb, however, is the irritation or injury which it is liable to suffer during the process of parturition or abortion. When it is confirind, indeed, how much preface different parts of this organ necessarily undergo, during these processes, even by the long continued actions of the uterus itself upon the body of the child; and that, in the early part of labour, it not unfrequently occurs, that the lower segment of the uterus is protruded into the cavity of the pelvis, along with the head of the child, and in this situation is squeezed between the head and the sides of the pelvis; (not to mention the occasional necessity of using instruments;) it must be obvious that many causes of violence will be applied in a natural labour, and more in difficult and preternatural cases. Perhaps the free discharge of the lecithy, which is a necessary concomitant of the separation of the placenta, serves the secondary purpose of local depletion, and thus, like a copious blood-letting instituted by art, prevents the evil which would otherwise be very likely to ensue. This supposition is rendered further probable, from the circumstance that inflammation of the uterus, when it comes on a few days after child-birth, commonly arises where the patient has been exposed to cold, by being taken out of bed too early, a practice deferedly reproved by Sydenham; and it is connected with a suppression of the lochial discharge. See Clarke's
Hysteritis.

Inflammation of the subsance of the uterus, when it exists, is tolerably well marked by its symptoms. It usually begins about the second or third day after delivery, and is first known to exist by a lembation of pain felt at the lower part of the abdomen, which gradually increases in violence, and is disfigurably from after-pains by its continuance. After-pains are intermittent, like the pains of labour, depending, like them, upon contractions of the uterus; but the pain of inflammation, arising from the uninterrupted action of the vessels, is necessarily unceasing. The patient complains much of any pressure applied externally to the region of the uterus, and this organ feels larger than common under the hand, as well as much harder, resembling almost a stone in firmness. Marks of constitutional affection soon appear in the increase of heat over the whole body, a white and dry tongue, thirst, headache, a hard, full, and strong pulse, (when the disease occurs in full habits,) and in all cases a frequency of pulse, from 100 to 120 strokes in a minute. Very soon after the attack, the urethra is usually affected with trifles and vomiting; but this symptom is not invariably present. There is commonly a considerable degree of pain in the back, shooting into the pelvis, and down the thighs. Not only the lochial discharge, but also the secretion of milk is for the most part interrupted. The bowels are variously affected; often colive in the commencement of the disease, but frequently very loose as it advances. The urine is commonly high-coloured, depositing sometimes a pink-coloured sediment, when it can be seen unixed with the uterine discharge. It will sometimes be found, when the disease has communicated with the neck of the bladder, or when the uterus and bladder have suffered, that suppression of urine will take place, so that the catheter must be employed two or three times a day to draw it off. On the other hand, we have seen the inflammation apparently extend to the kidneys, in which case no urine was secreted for two or three days; yet the patient experienced the sensation of an urgent desire to make water, probably from the inflammation being likewise communicated to the neck of the bladder. If the inflammation is very great, it may spread to the peritoneum covering the fundus of the uterus, and liasing the cavity of the belly; in which case there is great swelling, tension, and foreness of the belly, and other new symptoms arise, such as characterize the child-bed fever, described in another place. See Peritonitis Puerperarum.

In the progress of the disease, slight flowerings frequently take place at different times in the day, while the acetousness of the pain is diminished, and the face of the patient becomes occasionally flushed. These symptoms, together with the increased frequency and weakness of the pulse, mark the tendency of the disease either to suppuration, or to a dangerous failure of the vital powers. The tongue puts on a fiery red or scarlet appearance, which is often followed by aphthae; symptoms of general great irritation succeed; and the patient is often cut off in a short time. Now and then, however, a flow of fetid lochia relieves these symptoms, the pulse becomes less frequent; the flowerings more rarely appear; the tongue grows paler, and the skin, which before had been hot and dry, now relaxes and is cooler; a spontaneous diarrhoea comes on, and the patient recovers. (Clarke, loc. cit.) The cafe is more favourable, and the prospect of recovery greater, when these flowerings and flowerings have never occurred; but where the uterus gradually becomes softer, and its tender on pressure, the lochial discharge returns in its usual quality and quantity, and the secretion of milk begins again.

Of all the acute diseases, to which women are liable in the puaperal state, inflammation of the womb appears, on the whole, to be the least fatal; partly, perhaps, because the pain and fever accompanying it, at a time when the patient is necessarily under the care of her medical attendant, speedily call for the application of remedies. When the disease destroys life, it is usually by symptoms of extreme irritation; sometimes it goes on to suppuration; but rarely, it would seem, to mortification. It is true, as Dr. Clarke observes, that mortification has been often described as occurring in the uterus; but he is satisfied from experience that this has been chiefly said to happen by persons not habituated to the examination of the bodies of women who have died in child-bed, and who have mistaken the appearance of that part of the uterus, to which the placenta had adhered, for gangrene; whereas, it is commonly only the remainder of the maternal portion of the placenta, and of the coagulum of blood formed at the extremities of the large vessels of the uterus, upon the separation of the placenta; and a very little attention, by gently scraping off this subsance, will detect the found internal surface of the uterus beneath.

On distillation, after death produced by *Hysteritis* in puerperal women is commonly contained in a larger quantity, than very few in its subsance, but larger than when naturally contracted. Upon cutting into it, pus is often found, which is situated in the large veins, and not in any circumferenced cavity, like that of an abscess. Inflammation is often observed running along the Fallopian tubes, and into the ovaries, which when cut open are found loaded with blood. Pus is also sometimes found in the cavity of the Fallopian tube, as well as in the subsance of the ovaries, which in some cases distended by inflammation and matter, so as to equal in bulk a pigeon's egg. When the inflammation has extended in the uterus simply, little or no extravasated or secreted fluids have been found in the cavity of the abdomen: the peritoneal surfaces have also been discovered free from disease in some cases. In others, however, the peritonaeum, which covers the uterus has been observed to be partially inflamed, as well as that covering the posterior part of the bladder. Clarke, loc. cit. Brille, Morbid Anatom. p. 364, 2d edit.

When the symptoms of inflammation of the uterus concur with the puerperal state, or severe abortion, little doubt will arise as to the seat of the disease. But when it occurs in the uncompregnated state, the symptoms of inflammation may be mistaken for those of inflamed bowels, kidneys, or bladder, if not very attentively investigated. When, however, we observe a woman complaining of a burning pain, with a sense of weight and distention in the lower part of the belly, the pain being constant, fixed, and throbbing; when there is also a pain in the loins, frequently shooting round the pelvis to the groins, and down the thighs; and in addition to these, an acute fever, with trifles at the throat, and extreme repletion, little doubt can remain respecting the existence of inflammation in the uterus. An examination per vaginam, when the ovit is will be found extremely tender and painful to the touch, will more completely decide the matter, where it is permitted. The inflammation, however, is liable to be complicated, in this case too, by extending to the kidneys, bladder, and other contiguous parts; and a degree of stranguary and tenesmus (or visitia delire to go to stool) is liable to occur from the mere vicinities of the uterine irritation.

Cure of Hysteritis.—As the disease, therefore, is often extended to different organs at the same time, and the symptoms must necessarily be rather complicated, the functions of all the suffering organs being in some measure deranged, an accurate distinction of the seat of the disorder is often difficult. This, however, is the less, important, as the same remedies
remedies will remove the inflammation, in whichever viscus it may occur. Of these, blood-letting is the most efficacious; and, even in the puerperal state, in strong constitutions, it should be the resort, and liberally employed. In the disease happening independent of parturition, it cannot be omitted with safety, perhaps, under any circumstances; but the remission of it must be determined by the constitution of the patient, the violence of the symptoms, and the effect of the previous bleeding on the disease. It may frequently be found necessary a second and a third time. But in less robust habits, it will be expedient, if the symptoms, although diminished, have not been entirely removed by the first bleeding, to take away more blood by applying fix or more leeches, included in a bain, to the belly, or by cupping the skin of the abdomen. A blister may also be applied to the belly, as near the seat of the pain as may be. Dr. Clarke, however, is of opinion that these applications are not so beneficial in this affection, as in some other inflammatory disorders; and thinks that he has often observed them to increase the frequency of the pulse, and the irritation in the flumen at large. At the same time, the decided advantages obtained from blisters, in peripneumonias and other internal inflammations, lend him to speak hesitatingly against the general employment of them. Gentle cathartics, especially of the saline class, are evidently useful in the case of hydropsis, unconnected with child-birth; but in that which follows delivery, a course of purging is not to be recommended. It is always right, indeed, in the first instance, to procure two or three evacuations from the innerves; but, afterwards, it will generally be enough to preserve the regular motions of the bowels, by giving, from time to time, small quantities of calomel oil, or a little rhubarb mixed with some saline purgative. Dr. Clarke states this objection to long continued purging, that it has the effect of preventing that gentle perspiration, which, if it can be produced and kept up, does more towards curing the disease than any internal remedy can effect. With a view of producing this salutary determination to the skin, small doses of antimony and opium, or the compound powder of ipecacuanha, which bears the name of Dr. Dover, with the addition of a little rhubarb, and an occasional saline draught, may be usefully administered. In cafe a spontaneous diarrhoea should come on, it should not be interfered with, farther than taking care that the strength of the patient be not too much reduced by it. Except where there is reason to suspect the existence of undigested or indigestible aliment in the stomach, the action of vomiting should always be avoided; inasmuch as it constantly increases the pain by the agitation which it occasions, and the pressure made by the muscles of the abdomen on the inflamed uterus. It is scarcely necessary to add, that, during the whole course of the disease, every thing heating and stimulating should be cautiously avoided; that the food of the patient should be of a mild and digestible nature, consisting of liquid and vegetable substances, and her drink watery and diluent, every sort of animal food, and of fermented and spirituous liquors, being abstained from. As hysterics occurs, both connected with and independent of parturition, particularly in those who indulge in full diet, and in the use of heating food and liquors; so the prevention of the disease must depend principally upon temperance and regularity in this respect. In the former case, this end may be obtained by attention to the proper management of the woman both before and during labour. If the diminution of pain, and the accession of sweatings, announce the commencement of suppuration, little if any is to be feared, can be done by medicine. Under such circumstances, a great proportion of patients will be carried off. The most favourable tendency of the suppuration will be, when the pus is in the veins of the uterus, or in the Fallopian tube, that it may escape into the cavity of the uterus. The only means within the power of the physician, in this case, are to recommend a milk-diet, or one other light and nutritious aliment, and to soothe the irritation and pain by moderate doses of narcotic medicines.

Hysteria, in Botany, a name given by Persoon and others to a species of Fungi, composed of various species, among which is the Lichen pellucidus of preceding authors, but this name will probably not be retained.

Hysterecele. In Surgery, a rupture, or hernia, containing the uterus. The term is derived from ĝretioi, the womb, and κελευ, a tumour. See Hernia.

Hysterocystica, a retention of urine, arising from the prejudice of the uterus upon the bladder.

Hysterolithicus, from ĝretioi, the womb, and ᷆η, stone, or Convolvulus, in Natural History, a stone thus called, from its resemblance to the external parts of generation of the female sex. This is a species of helmintholithus in the Linnean system. These stones are found in great abundance near the clefts of Branbacht, upon the Rhine, in the confines of the landgrave of Hesse.

Hysterolithicus is also a name given by Ol. Wormius (Museum, p. 83.) to the caft or infinite imprest of a sort of Anemia shell, as Dr. Woodward states in his Letters on the Method of Fossils (p. 100), and thus gives the absurdties of the tales which had been related of this stone. This species of anemia occur with myrtilia, in argillaceous rubble-stone, or slate. Kirwan's Geo. Essays, p. 244.

Hysterology, τρεπολογία, signifying a discourse inserted, in Rhetoric, a species of hyperbaton, or a vicious manner of speaking, wherein the natural order of things is inverted; called also by the Greeks τρεπολογία, τρεπολογία; of putting the fifth thing where the last should be.

Thus Terence uses Սατοί and Բայի, for Երևայ and Դաշտ, and Virgil marianum & in media arma ruamus, for in media arma ruamus & marianum. Quintilian exposes this fault, lib. xi. cap. 2, where he says, quaedam — turpiter conversantur, ut si peperiffe narres, deinde concepisse; in quibus, si id quod pecuriae est dixeris de priore taceare optimum est.

Hysterophorus, in Botany. See Parthenium. Hysteropotmii, γγγάχος, in Antiquity, the same with dentepotomi.

Hysteroptosis, in Surgery, a bearing down of the uterus.

Hysterotomia, from ĝretioi, the womb, and τομη, a section, the operation of cutting through the parietes of the abdomen into the uterus, for the purpose of extracting the fetus, a proceeding sometimes necessary: the Cæsarian section.

Hysterotomocy, γγας, an operation more usually called the Cæsarian section.

Hystrix, in Zoology, a genus of mammals, in the order Glire, the fore-teeth in which are two in number, and cut off obliquely; the grinders eight; toes either four or five; and the body covered with spines and hair. These constitute the porcupine genus of English writers.

Species.

Cysta. Anterior feet four-toed; posterior pair five-toed; head crested; tail short. S. G. Gmelin. Hystrix ca-

The length of this species is about two feet; the head long and compressed; the front short and obtuse; the upper lip close to the nostrils; eyes small, and black; ears oval, broad,
broad, and short; tail conic and spinous; feet short; hair between the spines cinereous; the spines long, stout, smooth, and annulated with black and white. The length of these spines, and also the bristles of the neck, is about three inches in plethura. This animal is found in Asia, Africa, and the south of Europe, as Italy and Spain; it burrows in the earth, where it forms a number of convenient apartments, with a single entrance. During the day time the porcupine remains in its burrows; which it leaves at night in search of fruits, roots, leaves, and other vegetables of which its food consists. When threatened it rolls itself up like the hedgehog, and presents its formidable armament of spines, for it has no other means of defence, but this is alone sufficient to repel the tenacity of most animals that venture to attack it. The porcupine brings from two to four young at a litter, is easily tamed, and the flesh is reputed excellent for the table. There appear to be several varieties of the common porcupine.

A native of the woods of Brazil, New Guinea, and New Spain. This species climbs trees, feeds on fruits and small birds; grunts like the swine, rolls itself up, sleeps in the day, is easily tamed, and is taken for the sake of its flesh, which is esteemed an article of food. The length of the body is nearly twenty inches; the tail seven inches; the whiskers are long and white; feet cinereous; claws strong and black. A supplefused variety, with the tail longer and spines shorter, (Hystrix longius cinerus, breviorbus aculis,) is described by Barrer. Fr. équin. The animal called Hoitza luzatza, leu Tlaczatzin, by Hernandez and Niehemberg, is probably known to Gmelin to be another variety of this kind; it has the tail short and thick; a third kind is said to be family than the common Brazilian porcupine, and has the head white. Mexican. Tail long, prehensile; hind feet four-toed; spines nearly concealed among the long hair. Mexican porcupine.

Length eighteen inches; tail nine inches; body ducky. This kind inhabits Mexico.

Inhabits North America; the body is ruddy brown above; tail beneath white at the tip; and the spines nearly concealed among the hair. This animal is nearly the same as the last; it digs holes under trees, and feeds on fruits and the bark of the juniper. The Canadian porcupine is sometimes found entirely white.

MICHAUCLA. Feet five-toed; tail very long; spines clubbed or jointed. Schreber. Porcus aculeis fusciffris, S. & H.

The ears in this species are short and naked; the tail the length of the body, the tip crowned with a tuft of long, knotted, silvery hairs; body short and thick; ears short and naked; and the eyes large and bright. Inhabits the woods of the islands in the Indian ocean.

HYTHE, or Hith, a port, wharf, or little haven, to embank or land wares at. Such is Queen-bith, &c.

HYTHE, or Hith in Geography, a market town and one of the principal Cinque Ports, is situated in the parish of Saltwood, hundred of Hane, and county of Kent, England. Its name signifies, in Saxon, a port or haven; and it was anciently of far greater importance, as a maritime town, than at present. Leland says, “it hath bene a very great town by length, and containeth in three parochies, that now be cleane deliered: that is to say, St. Nicholas parochie, Our Lady parochie, St. Michael’s parochie, and Our Lady of Welthele.” — And again “to count from Welthele to the place wher the shieldons of the towne ys now, ys ii good myles yny length along on the shore.” He mentions a fire in the reign of Edward II., which destroyed nearly four hundred houses, and was followed by a pestilence; so that the town was greatly diminished. In the beginning of the next century, it again suffered much from similar visitations. At the time of the maritime survey, in the reign of Elizabeth, there were 122 inhabited houses in Hythe, and persons “lacking habititation” ten: its shipping consisted of fifteen trawellers, at five tons; seven hooters, of fifteen tons; three crayers, of thirty tons; and four crayers, of forty tons. Since this survey, the haven has been wholly lost, and the sea beach now nearly three quarters of a mile from the town. According to the returns under the act of 1801, the number of houses in Hythe was 217; that of inhabitants 1365. The houses are chiefly comprised in one long street, running parallel with the sea; but having two or three lefer ones branching off at right angles. The civil government of the town is vested in a mayor, twelve jurats, and twenty-four common-council-men; by whom, together with the freemen, the representatives are elected; the number of voters being about 180. The first return of barons to parliament from this port, was in the forty-second year of Edward III. The church occupies a very elevated situation on the acclivity of the hill above the town. It is built in the form of a cloister, with a tower at the west end, and appears to have had originally another tower, rising above the roof, from the interjection of the nave and transept. The west tower, with the fourth end of the transept, was rebuilt between the years 1348 and 1351, at which time the whole church underwent a general repair. Near the altar, on the south side, but partly concealed by the window, are four beautiful stone seats, with trefoil heads, and a range of circles and quatrefoils above them. The church-yard commands a fine view of the sea, and coast of France. Near the middle of the principal street are the court-hall and market-place; and in one of the streets leading towards the beach, on the opposite side, is a small theatre. In this parish are two hospitals, or almshouses, of ancient foundation; the one called St. John’s, the other St. Bartholomew’s. The former was founded for lepers previously to the year 1336, but at what particular era is uncertain; the other was built by bishop Hamo Noble, surnamed De Hythe, from his having been born in the town; and its deed of foundation, which is printed in the Registrum Roffenfe, describes it as “erected on the spot where he and his ancestors had their origin.” Besides the Martello towers that have been recently erected along this coast, there are several small forts on the beach in this vicinity, which were built shortly after the commencement of the last war. On the heights immediately above Hythe are extensive ranges of barracks for infantry, erected since the beginning of the present century; and near these are numerous mud-wall cottages for the wives and families of the soldiers. Other barracks, of a temporary kind, are within the town. Hythe is distant from London 67 miles; and has a weekly market on Thursday.

About one mile north-west from Hythe stands Saltwood castle, the original foundation of which has been attributed to the Romans, though probably on insufficient authority. Kirkburn says, that it was erected by Osef, son of Hengit; and Groot states that “on examining these ruins, every stone of them evidently appears to have been laid by the Nor-
The entrance into the first court was by a gateway, now in ruins, defended by a portcullis; the outer walls were strengthened by several circular and square towers, all of which are dilapidated.

About half a mile from Saltwood, westward, is Sandling, the new seat of William Deeds, esq. who has built here a large mansion, under the direction of Bonomi, on a hill which commands fine views of the sea, and yet looks down on its own demesne, consisting of wooded valleys, and richly rural scenery,possessing many beauties. Hasted's Kent, vol. iii. Beauties of England and Wales, vol. vii.

I and J.

I

The ninth letter of the English alphabet, may be considered both as a vowel and a consonant; agreeably to which two different powers, it has two different forms; though, since the vowel and consonant differ in their form as well as sound, they may, as Dr. Johnson observes, be more properly accounted two letters.

The Hebrews call the j consonant jod,  י, from י, land and space; because it is supposed to represent the hand clenched, so as to leave the space underneath void. With them it was pronounced as the consonant y, as it still is among the Germans, and some other people. The Greeks had no j consonant, and for that reason used their vowel i instead of it, as coming the nearest in sound. The letter i was used as a consonant among the Latins. In English j consonant has invariably the sound found with that of g in giant; and serves to molly that of the vowels; as in jew, j skeptical, j vowel. A vowel varies in its sound: in some words it is long, as fax, things, &c. In others short, as fn, thin. Prefixen to e, it makes a diphthong of the sound found with the oft: h, or double ee, in field, yield, except in friend, which is pronounced friend. Subjoined to a or e, it makes them long, as fail, eigh; and to o makes a mingled sound, which approaches more nearly to the true notion of a diphthong, or sound composed of the sounds of two vowels, than any other combination of vowels in the English language, as elf, coin. The sound of i before another i, and at the end of a word, is always expressed by y. Johnson.

The vowel i, according to Plato, is proper for expressing fine and delicate, but humble things; on which account that verle in Virgil,

"Accipiant inimicum imbre, remisique fatiscant,

which abounds in i's, is generally admired.

The vowel i was the only vowel which the Romans did not mark with the dash of a pen, to shew when it was long; instead of which, to denote it long, they used to make it bigger than ordinary, as in Pife, Vieux, &c. According to Lipius, they often repeated it when it was to be long, as in dli. They sometimes also deoted the length of this letter by adding e to it, and turning it into a diphthong, as dlevi for de, commis for annus, &c.

I, in Grammar, it, Gothic, ic, Saxon, ich, Dutch, is a pronoun personal. By Shakspeare I is more than once written for ay, or yes: e g.

"Did your letters pierce the queen?"

— I, sir; she took 'em and read 'em in my presence,

And now and then an ample tear trill'd down."

I, in Logic, denotes a particular affirmative proposition. I was anciently a numeral letter, and signified a hundred, according to the verle.

"I. C. compar erit, et centum signifiere,t"

I, in the ordinary way of numbering, signifies one; and when repeated, it signifies as many units as it is repeated times. When put before a higher numeral, it subtracts itself, as IV, IX, &c. but when set after it, it is added as often as it is repeated; as VI, XI, VIII, XIII, &c.

In abbreviations and ciphers, I frequently represents the whole word Jesus, whereas it is the first letter.

Neither the long nor the short I, the consonant ja, nor the vowel I, is the initial of any technical term in Latin.

I, in the French Coinage, characterizes the money of Limoges.

J.

J, in Geography, a town of Sweden, in East Bothnia; at the mouth of the river Jafri; 12 miles N. of Ulen.

Ja. St., or St. J. A., a town of France, in the department of the Seine, situated on the Naviglio, containing five churches. N. lat. 33° 29'. E. long. 8° 35'. See St. Agatia.

JAAATSURU, a town of Japan, in the island of Nippon; 65 miles N.W. of Jedo.

JAB, a town of Africa, in the kingdom of Wubali, situated on the river Gambia.

JABA, a town of Africa, in Bambare, on the Niger. N. lat. 13° 15'. W. long. 4° 45'.

JABADII
JABADII ISSULA, an ancient name given to Sumatra, according to M. D’Anville, although others have supposed it to be Java. Ptolemy speaks of this island and says, that it abounded with gold. He calls the capital Argenta, the position of which seems to correspond with that of Achen.

JABAJAHITES, a sect among the Muffheimi, who, according to Riccius, teach, that God is not perfectly wise; that his knowledge does not extend to every thing; and that time and experience have furnished him with the knowledge of many things whereof he was before ignorant. Thus, say they, not being apprized from all eternity of every event that shall happen in the world, he is now obliged to govern it according to the chance and occurrence of those events.

JABARABA, in Geography, a town of Brazil, in the government of Minas Geraes; 32 miles S. of Villa Rica.

JABARIANS, a sect of Mahometans, in direct opposition to the Kadarmis, distinguished by denying free agency in man, and ascribing his actions wholly to God. They take their denomination from Al Jabr, which signifies necessity or compulsion, because they maintain that man is necessarily and inevitably constrained to act as he does, by force of God’s eternal and immutable decree. Some of these, who are more rigid in their opinion, are called pure Jabarians, and others, who are more moderate, are called middle Jabarians. The former will not allow men to have any power at all; affording that man can do nothing, and that he is deficient of power, will, or choice, as much as an inanimate agent. They assert also, that rewarding and punishing are the effects of necessity, and they also say the fame of the imposing of commands. This was the doctrine of the “Jahamins,” the followers of Jahan Ebn Safwan, who likewise held that paradice and hell will vanish, or be annihilated, after those who are defined to these habitations shall have entered them, so that at last there will be no existing being besides God. The moderate Jabarians ascribe some power to man, but such as has no influence on the action. As those who grant the power of man to have some influence on the action, which influence is called “acquisition,” some will not allow their being denominated Jabarians; whereas others reckon them in the number of middle Jabarians, and contend for the middle opinion between absolute necessity and absolute liberty, attributing to man acquisition or concurrence in producing the action, or in consequence of which he gains commendation or incurs blame; and they make the “Afharins” a branch of this sect. To the middle or moderate Jabarians, belong the “Jawahrians,” whose founder Al Hafan Ebn Mohammed at Najaf taught, that God created the actions of men, both good and bad, and that man acquired them, and that man’s power had an influence on the action, or a certain concurrence, which he called “acquisition,” agreeing in this respect with Al Aharai; and the “Afharins,” the disciples of Derar Ebn Amani, who also held that man’s actions are really created by God, but that man really acquired them. The Jabarians also say, that God is absolute Lord of his creatures, and may deal with them according to his own pleasure; so that if he should admit all men without distinction into paradice, it would be no partiality, or if he should cast them all into hell, it would be no injustice, concurring in this respect with the Afharins. Sale’s Prel. Dife.

JABBE, in Geography, a large town of Africa, in the kingdom of Bambara, having in it a Moorish mosque, and situated on the Niger; 55 miles S.W. of Segu. N. lat. 13° 59’. W. long. 3° 21’.

JABBUAH, a town of Hindoostan, in the circuit of Banwalsch; 25 miles S.S.E. of Tanda.

JABEZ, or JABEZ-GILEAD, in Scripture Geography, a city in the half-tribe of Manaffich beyond Jordan, situated in Gilead, at the foot of the mountain so called. Eusebius places it six miles from Pella towards Gerara.

JABEY, or YABEY, a district of Africa, on the Gold Coast, situated to the east of Anta, the soil of which is rich and fertile; but the gold obtained here is adulterated.

JABIRU, or JABIRU-GUACU, in Ornithology, the Myctera Americana; which bee.

JABLONOW, in Geography, a town of Poland, in the province of Breslaw; 64 miles N.W. of Breslaw.

JABLONOWSKY, Joseph Alexander von, in Biography, a Polish prince, who devoted himself chiefly to the sciences, and, for the sake of improvement, made several tours through Germany and France. When the troubles broke out in Poland he resigned his senatorial dignity, left the country, and took up his residence at Leipzic, where he distinguished himself not only as a friend and protector of science, but as a man of great literary acquirements. He founded a society which was named after himself, and assigned a liberal fund for the purpose of distributing premiums to the authors of the best answers to questions proposed on various literary subjects. This society still exists, holds its meetings at Leipzic, and occasionally presents the world with the fruit of its labours. The prince died in 1777, at the age of fifty-five. His works are, “The Lives of twelve Generals,” written in the Polish language; “A Treatise on the Sacred Poetic,” and some pieces of a similar nature. Gen. Bury.

JABLONSKI, Daniel Ernest, was born at Dantzic in the year 1660; he was educated partly at Liifa and partly at Frankfort on the Oder. He spent some time in his mature studies at Holland, and from thence he went to England, and took all the advantages which the university of Oxford could afford him. On his return to his native country in 1685, he was admitted to the ministry, and appointed pastor of the reformed church at Magdeburg. After some successive changes he was at length appointed to be minister to the court of Berlin. He was extremely anxious to promote an union between the Calvinists and Lutherans, and to introduce into Prussia a constitution of church government resembling that of the English establishment: but his well-meant efforts proved ineffectual. He was not however disheartened by want of success, but directed all his attention to the fame subject twelve years afterwards. Some account of the measures taken in this business will be found at the end of Dr. Machine’s translation of Molheim’s Ecclesiastical History. To this account is annexed “A Plan of Ecclesiastical Discipline and Public Worship,” drawn up by Jablonfski, and several original papers. In 1756, M. Jablonski received the diploma of doctor of divinity from the university of Oxford. In 1718 the king of Prussia nominated him counsellor of the Contiflity, in 1729 member of the Directory of the reformed churches, and in 1733 president of the Academy of Sciences at Berlin. He died at the age of eighty, in 1741. He was author of a great number of works, chiefly theological, but his most important were, 1. “Biblia Hebraica, cum Notis Hebraicis et Lematibus Latinos ex recensione, et cum Prefatione Latina, D. E. I.” 2. “Jura et Libratriaat Diffidentium in Religione Christiana in Regno Poloniae et Magno Ducatu Lithuanit, et legibus Regni, et alibi Monumentis authenticis excerpta.” Moreri, Molheim.

JABLONSKY, Charles Gustavus, private secretary to the queen of Prussia, and a considerable naturalist, began his career, as an author, by the publication of “A Syllen of all known indigenous and foreign Insects,” arranged according to the Linnaean system, and intended as a continuation of Buffon’s Natural History. The share which Jablonky
J A B

lonely had in this work extends only to the seventh sheet of the third part, relating to butterflies. His labours prevented him from continuing a work that demanded much labour and attention. It was carried on by Mr. H. Rutt, a clergyman at Berlin; who also continued another work on the description of the Scarabaei, begun by Jablonsky. Our author died in the year 1782, at the age of thirty-one, to the regret of his friends, who had high expectations from his talents and great affability. Gen. Bing.

JABLONSKY, John Theodor, brother of D. Ernæ, was born at Dantzic in 1624. He was educated partly at Amsterdam, and partly at Berlin, from whence he was sent to the Gymnasion of Konigberg, and then to Frankfort on the Oder. In 1680 he made a tour through Germany, Holland, and England, and in 1687 he accompanied the princes of Delft to Poland, where he remained till the death of the prince Radziwil, the husband of his patroness. He was now appointed secretary at the court of the duke of Saxe-Barby, and in 1703 was elected secretary to the Academy of Sciences at Berlin, then newly established. In 1715 he accompanied on his travels, in the capacity of tutor, Frederic William, hereditary prince of Prussia, and upon his return was appointed a counsellor of state. He died in 1733, leaving behind him a great number of very learned works, among which was "A General Dictionary of Arts and Sciences," which was afterwards augmented and improved by J. S. Schwabe, professor of philosophy at Leipsic. Gen. Bing.

JABLONSKY, Paul Ernest, son of Daniel Ernæ, was born at Berlin in 1693. His great talents were discovered at an early period, and having studied at Frankfort, and acquired a deep knowledge of theology and the Coptic language, he was admitted among the royal candidates; and at the king's expense made a literary tour through Germany, Holland, England, and France. In the course of his travels he had an opportunity of improving himself in the Coptic, particularly by conferring with the different works in that language at Leyden, Oxford, and Paris. In 1726 he was appointed professor of philosophy, and preacher to the reformed congregation of Frankfort on the Oder; in 1733, public professor of theology, and afterwards member of the Academy of Sciences at Berlin. He died in the month of September, 1757. He was author of many learned and theological works; and was by his labours of much service to biblical literature. Two of his principal pieces were "Rhempha Ægyptiorum Deus ab Israelis in Deferto cultus," and "Pantheon Ægyptiorum; five de Dis corum Commentarius."

J A L B L U N K A U, in Geography, a town of Silesia, in the principality of Teutsch, on the river Elbe, with an adjoining fort; 11 miles S.E. of Teutsch. N. lat. 10° 32'. E. long. 18° 28'.

J A B O K, or JABUK, in Scripture Geography, a brook on the other side of Jordan, whose spring was in the mountains of Gilead. It fell into Jordan, near the sea of Tiberias, south; and separated the land of the Ammonites from Ghalonitis, and that of Oq king of Bashan. Gen. xxxii. 42 to 43.

Gen. Ch. Cat. Perianth inferior, of one leaf, bell-shaped, in five nearly equal segments, permanent. Cor. of one petal, tubular, much longer than the calyx; tube nearly cylindrical; limb in five acute, somewhat spreading, segments. Stam. Filaments five, short, flat, inserted into the upper part of the tube, and scarcely extending beyond its circumference; anthers elliptico-oblong, capitate, with a small point. PERIC. and SEEDS unknown.

Eff. Ch. Corolla tubular. Stamens inserted into the top of the tube. Stigma capitate. Berry?

1. J. integrifolia. Lamareck. Illust. t. 112.—Leaves elliptic-oblong, slightly toothed.—Native of Buenos Ayres, where it was gathered by Commeron, from whole specimens alone, of this and the following species, any thing is known concerning them in Europe. They appear to be perennial herbaceous plants, of the size of a primrose, with several radical rather downy leaves, without any stem. Flowers on simple radical stalks, shorter than the leaves, the tube an inch and a half long, rather slender.

2. J. rumicata. Lamarc. n. 2.—Leaves lyrate. Tube of the corolla somewhat bell-shaped.—Gathered by Commeron near Monte Video. Its lyrate, deeply toothed leaves, and shorter bell-shaped flowers, much like that of Astropia Belladonna, sufficiently distinguish it from the preceding.

J A B O T A P I T A. See OCINA.

J A B O T I, in Zoology, the name of a remarkable species of tortoise found in America. The shell of this species is black, and has many hexagonal figures marked upon it; the head and legs are brown, variegated with spots of a dusky greenish hue. The liver of this species is accounted a very delicate food.

J A B O U, in Geography, a country of Africa, W. of Benin.

J A B R I N, a district of Arabia, S.W. of Hadsjar, abounding with salt.

J A C A, a town of Spain, in Aragon, at the foot of the Pyrenees, on the river Aragon; the seat of a bishopric of Saragossa. This ancient town, which has a cathedral built in 1552, was formerly the capital of Aragon, as it is now of a district, comprehending nearly 200 towns and villages; 45 miles N. of Saragossa. N. lat. 42° 25'. W. long. 41'.

J A C A, in Natural History, the name of a kind of nut, very common in China, which is reckoned the largest of all yet known. It is produced from the trunk of the tree, as if the branches, however large and strong, were not able to bear it; its shell is so strong, that there is occasion for an ax or hatchet to open it; and within are innumerable cells or vehicles, containing a pulp of a yellow colour, which surrounds a kernel like the cherry, that is exceedingly sweet when ripe.

J A C A R A, or JACARE. See TANAGRA Jacapa.

J A C C A, in Ancient Geography, a town of Spain, in the interior of the country of the Vasaoni. Ptol.

J A C C A T R A, in Geography, one of the empires of the island of Java, bounded on the E. by that of Cheribon, and to the W. by the kingdom of Bantam. It was formerly governed by its own kings; but the last of these, having been subdued by the arms of the Dutch East India Company in the year 1619, they have ever since policed it by the right of conquest, as sovereigns. It is under the immediate
immediate government of the governor-general and the council of India, and all the Javanees of Jaccatra are therefore born the company's subjects. Before this revolution, Jaccatra was the capital of the empire, but Batavia, which is built near the former, is now the chief place. The Prewanger lands are districts which did not in formerly belong to the kingdom of Jaccatra, but which have been united to the company's possessions since the year 1677; and the administration of them is divided between Batavia and the residency of Cheribon. The whole country of Jaccatra, with the Prewanger lands, is 110 Dutch miles in circumference, and comprises 30 districts, containing together 33,914 families, or 225,824 inhabitants; of which the district of Batavia alone includes 19,469 families, or 116,814 inhabitants. Hence it appears, that the other districts are much less populous, so that a great extent of excellent land remains uncultivated and neglected, and that which is tilled is owing to the industry and perseverance of the Chinese, who are settled here. The depopulation of Jaccatra has been chiefly owing to the conquests of the company, which having taken the capital and defeated the army of Bantam, carried away the inhabitants into the latter kingdom; in consequence of which Jaccatra remained for a considerable time nearly in an uninhabited state. Since the year 1753, however, the population has here been considerably augmented. Jaccatra is watered and fertilized by several rivers, of which the largest are the Sadi, or of the river of Tangerang, and that of Cawang, which descend from the inland mountains, and flow into the sea in a northerly direction. The river of Tangerang runs into the sea, not far from the point of Ontong Java, and near its mouth the company has a small port called the "Kwal." This river gives part of its water to a canal that supplies the canals and moats of the city of Batavia; but the greater part is furnished by other rivers. The productions of Jaccatra are principally coffee, sugar, and rice; likewise indigo, cotton, yarn, tumeric, and cajung, or lentils, from which Liff oil is pressed. In 1778 there were sold in Holland the following articles, being productions of the colony of Jaccatra: viz. 2,000,000 cobs. of sugar, at 4 shillings; 2,000,000 cobs. of coffee, at 11 shillings; 500,000 lbs. of pepper, at 17 shillings; 100 leagiers of arrack; 10,000 lbs. of candied ginger; cotton-yarn to the amount of 200,000 florins, and indigo to the amount of 1000 florins. This may be taken as the annual quantity of what Jaccatra is able to furnish for Europe, and the gain upon these articles is considerable, as none of them cost much; the pepper and coffee nearly 2l., and the fugar 15 shillings per pound of fugar, the company farther dispose every year full four millions of pounds weight in Japan, Surat, Malabar, and other establishments, from which they likewise make considerable profits; and about the same quantity, 450,000 cobs. is exported in private trade, together with immense quantities of arrack, rice, and other articles. See also the Voyages to the East Indies, &c. vol. 3. p. 14.

JACCHÀOGLI, 1800250579, in Antiquity, those who carried the statue of the hero Jacchus in procession, at the celebration of the Athenian festival called Littafina. They had their heads crowned with myrtle.

JACCHUS, in Zoology. See SIMIA.

JACEA, in Botany. See CENTAURA.

JACI, in Geography, a small well built and populous town of Sicily, in the valley of Demona, where a great quantity of silk is manufactured. It was formerly called Acis. (See Acis.) The modern town is situated far higher than the ancient city, if we judge from its actual elevation above the level of the sea, and the number of itsra of lava which are discovered in defending the flight of bees, leading from this town to the Caricatore, which is below it; 12 miles N. N. E. of Catania. Lat. 37° 40'. E. long. 15° 15'.

JACINA, a river of Naples, which runs into the gulf of Squillace. Lat. 38° 57'. E. long. 17°.

JACINTH, in Botany. See HYACINTHUS.

JACK, in Falconry, signifies the male of birds of sport. See FALCON and HAWK.

JACK, or Pike, in Ichthyology. See ESPEC LUCINUS.

JACK, in Mechanics, is an instrument in common use for raising heavy timber, or very great weights of any kind. See Plate XXX. Mechanics, fig. 1.

But as the wheel-work of this engine is included in the strong piece of timber B C, the inside of it is represented in fig. 2, where the rack A B must be supposed at least four times as long in proportion to the wheel Q, as the figure represents it; and the teeth, which will be then four times more in number, to be contained about three in an inch. Then if the handle H P be seven inches long, five turns of it i.e. five times 22 inches, or 110 inches, will be the velocity of the power, whilst the weight raised by the claw A, or depressed by the claw B, moves one inch: for as the pinion of the handle has but four leaves, and the wheel Q twenty teeth, there must be five revolutions of the handle to turn the wheel once round, whose three-leaved pinion R will, in that revolution, just move the rack three teeth, or one inch. This might have been also known without seeing, or even knowing the number of the teeth of the wheel and pinions, by measuring a revolution of the handle in fig. 1; and comparing the space gone through by it with the space gone through by the end A or B. This machine is sometimes open behind from the bottom almost up to the wheel Q, to let the lower claw, which in that case is turned up as at B, draw up any weight. When the weight is drawn, or pushed sufficiently high, it is kept from going back by hanging the end of the hook S, fixed to a flapple, over the curved part of the handle at B.

Jack is also the name of a well known engine used for turning a spit, the weight is the power applied; the friction of the parts, and the weight with which the spits is charged, are the force to be overcome; and a steady uniform motion is maintained by a can of the fly. See the construction of this engine more particularly explained and illustrated by a figure, under the article MECHEMICAL powers.

Jack, Smoke, is an engine used for the same purpose with the common jack, and is so called from its being moved by means of the smoke or rarefied air; ascending the chimney, and striking against the tail of the horizontal wheel A B, (fig. 3) which being inclined to the horizon, is moved about the axis of the wheel, together with the pinion C, which carries the wheels D and E; and E carries the chain F, which turns the spit. The wheel A B should be placed in the narrow part of the chimney, where the motion of the smoke is swiftest, and then the greatest part of its weight should be upon the flaps. The force of this machine depends on the draught of the chimney, and the velocity of the fire.

Jack, in a Ship, is a sort of flag or colours, displayed from a maff erected on the outer end of a ship's bowsprit. In the British navy the jack is nothing more than a small union flag, composed of the interfection of the red and white crosses; but in merchant-ships this union is bordered with a red field. See FLAG.

Jack is used also for a horse or wooden frame to saw timber upon; for an instrument to pull off a pair of boots; for a great leather pitcher to carry drink in; for a small bowl that serves as a mark, at the exercize of bowling; and for a young pike.

Jack, a Musical implement in a virginal, spinett, and harpsichord;
JAC

PARISIENSIS: it is a small machine, usually made of pear-tree-wood, in which is a tongue, armed with a quill. This tongue moves on a pivot, and when the quill has struck the firing, the jack being thrown up with the key, on the end of which it rests, if the fag is taken off, it returns to its place under the firing, and the tongue, thrown back by passing the firing, is forced into its perpendicular situation by the spring of a briskle behind it.

JACK-ARCH, in Architecture, is an arch of one brick thickness.

JACK-HEAD, in Hydraulics, a part sometimes annexed to the forcing-pump. See Pump.

JACK-in-a-Bucket. See HERMANNIA.

JACK by the Hedge. See ERISIMUM.

JACK-DRAW. (See COELUS MONANDA.) This bird is very much disliked by the farmer and gardener, and is of such a vicious disposition, that he will carry away much more than he can make any use of. There is a method of destroying this bird by a particular sort of spring, which is much practised in some parts of England, and is so useful, that it ought to be made universal. The method is this: a flake of about five feet long is to be driven firmly into the ground, and made to fall that it cannot move, and so sharp pointed at the top, that the jack-draw cannot rest upon it. Within a foot of the top there must be a hole bored through it, of three quarters of an inch in diameter; through this hole is to be put a flake of about eight inches long, then a horse-hair spring or morsel is to be fastened to a thin hazel-wood, and this brought up to the place where the short flake is placed, and carried with it through the hole; the remainder being left open under that flake. The other end of the hazel-rod is to be put through a hole in the flake near the ground, and fastened there; the flake is to be planted among the jack-draw's food, and he will naturally be led to fasten to it; but finding the point too sharp, he will deft to the little cross flake; this will fix with his weight, and the spring will receive his leg, and hold him fast.

JACK-DRAW, Purple. See GRACULA QUINCLA.

JACK-Ketch, is a name given by the populace to the common hangman.

JACK-in-a-Lantern. See IGNE FALNUS.

JACK-Snipe, in Ornithology. See SCOLOPAX CALLIMINA.

JACK WAMBÄFUM, in our Old Writers, a kind of defensive coat-bracer, worn by horsemens in war, not made of solid iron, but of many plates fastened together; some of which perrons by tenure were bound to find upon any invasion.

JACK, Wood, a sort of wood made use of for sawing or cutting wood upon.

JACK ALLE, in Zoolag, the name of a creature of the dog-kind, the cat's avatar of Limnus, called by authors LAPIS AVENS, the gold-coloured wolf, and by the modern Greeks PAKALI. See AURUS.

JACKSON, John, in Biography, was born at Senley, near Thrift, in Yorkshire, in 1666. He was educated at Doncaster, under Dr. Henry Bland, afterwards head-master of Eton school. From Doncaster he went to Cambridge, and was entered, in 1702, of Jesus college. Here he took his degree of B.A. and quitted the university in 1707, and engaged himself as private tutor in the family of a gentleman of Derbyshire. In the following year he was ordained, and soon after obtained the rectory of Roffington, which had been referred to him, by the corporation of Doncaster, after the death of his father. In 1714 he commenced his career as author, by publishing three letters in defence of Dr. Samuel Clarke; one on Scripture Doctrine of the Trinity, under the name of a country clergyman. This work was the means of introducing him to the notice of Dr. Clarke, who was anxious to procure for him some preferment in the church. In 1714, Mr. Jackson engaged in the Bungsran controversy, and proved an able defender of bishop Holdly, in the cause of liberty. In 1716 he engaged in a controversy with Dr. Waterland, in defence of the sentiments maintained by Dr. Clarke. He purposed the subject still farther in a correspondence with Mr. Whiston, by which he was led to determine never more to sublimate to the thirty-nine articles. In consequence of this resolution, he left, about the year 1724, the hopes which he had been led to entertain of a prebendary of Salisbury, which bishop Holdly refused to give him without sublitation. This refusal was so extraordinary, especially as it came from Holdly, and as the latter did not make sublitation necessary, that the prebend was contested for it by his best friends. Whiston exclaimed, "how confident this was with his own notion of liberty of conscience, or with that Christian freedom, of which he was always an advocate, I do not well understand." Upon the death of his friend Dr. Clarke, in 1749, Mr. Jackson was presented to the masterhip of Wington's hospital, in Leicestershire, by the duke of Rutland, which place he filled, till his death, with much reputation and credit, candidly admitting into the house persons of different religious persuasions, even some who had been violent partizans against him. Mr. Jackson next appeared as an author in defence of human liberty, or the liberty of the will, in opposition to Anthony Collins, who had published a pamphlet in behalf of the doctrine of necessity; he also wrote in justification of human reason; and in defence of the Christian religion, in opposition to Taylor's work, entitled "Christianity Old as the Creation." His other smaller treatises we shall pass over, though very useful and important in the controversies and discussions of the period in which the author flourished. In 1753 he felt his great work into the world, entitled "Chronological Antiquities, or the Antiquities and Chronology of the most ancient Kingdoms from the Creation of the World, for the Space of Five thousand Years." This work, the result of much patient application, and very extensive reading, consisted of three volumes 4to., was well received by the literati of our own country, and was translated into the German language. He had other works in view, particularly an edition of the New Testament in Greek, with scholia in the same language; this he meant to have accompanied with all the various readings which he had collected, but the infirmities of age prevented him from accomplishing his designs. He died in 1765, in the 78th year of his age. He was a man of deep and very extensive learning, particularly in Greek and Roman literature; and his mind was indefatigable. He was the avowed friend of civil and religious liberty, and was never afraid of avowing the truth on any subject, although he was fully sensible of the obloquy and temporal losses to which such conduct would expose him.

Biog. Brit.

JACKSON, Thomas, was born at Witton, in the county of Durham, in the year 1779. Having obtained a good classical education, he was entered of Queen's college in the year 1795, and in the following year he was, on account of his great merit, unanimously elected a scholar of Corpus Christi college, notwithstanding the utmost interest was made for another candidate. He took his degrees in regular course, and was at length chosen vice-president of his college several years successively. He first obtained a benefice in his native county, which, in a short time, he relinquished for the vicarage of St. Nicholas, in Newcastle-upon-Tyne. He was in 1799 a rigid Calvinist, and was much admired and followed as a preacher. Being afterwards appointed chaplain to Dr. Niel, bishop of Durham, that prelate was the
means of making him a convert to Arminianism. In 1650 he was elected president of Corpus Christi college, on which occasion he resigned the vicarage in Newchurch, and soon afterwards was nominated chaplain in ordinary to his majesty, and collated to the vicarage of Witney in Oxfordshire. In 1655 he was made a prebend of Winchelsey, and in 1658 he was promoted to the deanery of Peterborough. He died in 1660, leaving behind him a character for a solid and penetrating judgment, and for extensive and sound learning. His works are numerous, but wholly theological; the principal of them consist of "Commentaries on the Apostle's Creed," in twelve books. His works, thirty years after his decease, were collected and published in three volumes folio, to which is prefixed the life of the author. Biog. Brit.

Jackson, William, an eminent musical composer, was a native of Exeter, in Devonshire. He was pupil of the celebrated Travers, and may be said to have imbied no small portion of that composer's spirit. It must be allowed that Jacksonpossessed a considerable share of intellectual ability, and evinced on many occasions a very distinguished taste for the fine arts. His judgment in general was found; genius will not be denied him, and when genius, judgment, and talent are united, one cannot expect an approximation to human excellence. At the same time it must be confessed, that these qualities were strongly alloyed by a mixture of selfishness, arrogance, and an inatilable rage for superiority.

In many of his musical compositions he has displayed traits of novelty, but these are not the most estimable of his productions. The "Elegies," the bell of his works, posfesses superior melody, for which we may allow him credit; but the harmony of these is in some measure derived from his old master; that is, they are constructed upon the model of that composer's canzonets. Indeed, many of Jackson's early compositions favour much of the spirit and contrivance of Travers.

Jackson's fame, in a great measure, may be said to have been founded in his judgment of election with regard to poetry; though he sometimes took unwarrantable liberties with his author, in order to accommodate the lines to his music. Perhaps no composer copied less from others than Jackson, yet at the same time it must be admitted that he was a palpable plagiarist. His most interesting and novel melodies are too frequently aseociated with common paragages that have existed almost from the origin of music; the defect of four notes in the ditonic order is sufficient to illustrate our meaning. Jackson's peculiar fort exalted in giving an elegant and plaintive melody to elegiac poetry. To constituting harmony, without rendering the middle part or parts of a composition destitute of melody, Jackson stands unravelled.

This is no trivial praise, when it is known that, before his time, composers were, and are at present, very defective in this part of their art. It was a defect in Jackson's muse, that his melody would suit any species of plaintive lines; few of his compositions displayed the art of mingling expression with melody, and preferring the latter in its purity. His "Fairy Fantasies," not yet published, evince more congruity than any others of his works.

Jackson paid his court to the graphic muse, but never looked at nature, believing, that by copying other masters, he might at last arrive at excellence. His great model was his friend Gainsborough, whose colouring and composition he constantly endeavoured to imitate, sometimes with a degree of success which induced him to lay a false claim to the merit of originality. But had he succeeded in even equalling that great artist, his pictures would not have spoke the language of nature; the man who merely copies another, either in music or painting, can never be considered a great artist; he can only be a faint echo, and ranked among the servile puce imitators.

Jackson was elected organist of St. Peter's cathedral, Exeter, in 1777, and continued in that situation till his death, in 1803.

Though his general mode of living was temperate, yet he thought that a still greater abstinence would prolong his existence. He latterly dined on milk-porridge, and drank water. This experiment was fatal. His habit necessarily became impoverished, and his existence terminated in a dropsey, at the age of 73.

Jackson, in Georgia, a county of America, in Georgia, containing 27,767 inhabitants, of whom 1400 are slaves. Also, a county of Tennesee, in Mero district.

Jackson, Port, a bay or harbour on the E. coast of New Holland, so called by lieutenant (afterward captain) Cook, who discovered it in May 1770, and found that it had good anchorage. This is one of the noblest harbours in the world, extending about 14 miles in length, with numerous creeks and coves. On the south of this, at a spot called Sidney cove, a settlement for transported criminals was fixed. Jackson lies three leagues N. of Botany-bay; which see. See also New Holland.

Jackson's River, a head-water of James's river, in Virginia, which rises in the warm spring mountains, and runs S.W. through the valley, until it is joined by Carpenter's creek, when the river assumes the name of Huvanna, and flows S.E. About 4 of a mile from its source, it falls over a rock 200 feet into the valley below. It is near half as high as Niagara, but only 12 or 15 wide.

Jacksonborough, a port-town of America, in Screvin county, Georgia; 670 miles from Washington.

Jacksonia, in Botan, so named by Mr. Robert Brown, in memory of the late Mr. George Jackson, F.L.S. a man of the most excellent and amiable character, devoted to the science of botany, to which, under the auspices of his patron and friend, A. B. Lambert, esq, he has rendered several important services. The improved style of the Botanical Repository, for some time past, though far short of what he wished, is owing to his care, and he has furnished a paper in the tenth volume of the Linnaean Society's Transactions, on a new genus of Decandrous Leguminous plants, named Ormosia. Many manuscripts evincing his learning and scientific skill remain in the hands of Mr. Lambert. Mr. Jackson died of a rapid decline Jan. 12, 1811, aged 54, and was interred on the 16th in St. George's burying-ground, Mary-le-bone. He was a native of Aberdeen.—Brown in Brit. Hor. Kew v. 3. 12.—Cliffs and order, Decadea Monogynia. Nat. Ord. Papilionaceae, Lin. Loganiaceae, Juf.

Gen. Ch. Col. Perianth inferior, of one leaf, in five deep, nearly equal, acute segments Cor. papilionaceous, of five petals. Standard interweave heart-shaped, about equal to the calyx. Wings rather longer, obtuse, with a tooth on their upper side near the base. Keel of two petals, of the size and shape of the wings. Stam. Filaments ten, awl-shaped, dilated, equal, acuming deciduous; anthers roundish. Pfl. German near feathery, oval; style awl-shaped, slender;
JAC

flander; stigma simple, obtuse. Paric. Legume ovate or oblong, somewhat swelling, of one cell and two valves, downy on their inside. Seeds two, roundish, without any appendage.

Of this genus, whose habit is slender and resembling that of Broom, two species are defined in an unpublished sheet of the third volume of the Hortus Kewensis, kindly communicated to us by Mr. Brown, that the memory of his friend might as soon and as widely as possible be commemorated. There are,

1. J. jepara. Brown MSS. — "Stem arborescent, without thorns. Branches angular. Clusters terminal."—Native of New South Wales, from whence it was sent to Kew garden by Mr. George Caley, in 1803. This is the plant mentioned in Sims and Koenig's Annals of Botany, v. 1. 511, which the author of the effay there printed, and of the present article, for want of the fruit, could not then venture to determine. Its branches have the aspect of a Spartium, and are somewhat silky, leafless, much branched, and angular. Flowers yellow, in scattered short clusters. Specimens were long ago sent from Port Jackson, by Dr. White.—This species is kept in the green-house, and flowers from June to August.

2. J. jepara. Brown MSS. (Gompholobium spinosum; Billard. Nov. Holl. v. 1. 107, 7. 136.)—"Stem shrubby. Branches spinous, spreading, twice or thrice forked, angular. Branches very short, closely pressed to the top of the flower-bud."—Native of the south-west coast of New Holland, from whence it was sent to Kew, by Mr. Peter Good in 1803, and is kept in the green-house, flowering most part of the summer. The stem is much branched, rigid and spinous, without leaves. Flowers white, usually in pairs. Billiard says the seeds are from two to four, and kidney-shaped.

Several more species of Jacksonia are defined to appear in Mr. Brown's Prodromus Fl. Nov. Hollandiae, with which, we presume, the above specific characters are contrasted. S. JACKSONSBOROUGH, in Geography, a small port-town of South Carolina, on the W. side of Edisto river, about 33 miles W. of Charleston.

JACKTALL, a town of Hindoostan, in Dowlatabad; 12 miles N.W. of Ramgar.

JACMEL, a jurisdiction and sea-port town on the S. side of the island of St. Domingo. This jurisdiction, in the French part of the island, contains three parishes, remarkable for the goodness of its soil, and the abundant crops of coffee. The town is situated on the S. side of the neck of the south peninsula; 6 leagues westward of Cayes de Jacmel, or 13 S.W. of Port-au-Prince, and 53 E. of cape Tiburon. N. lat. 18° 21'. W. long. from Paris 75° 2'.

JACMAL, Cayes de, a town and parish on the E. side of the stream of its name; the parish is bounded E. by the plain on the Spanish part, at the foot of the mountains of Bahoruco, 60 leagues square, fit for any kind of cultivation.

JACO, a river of Brazil, which runs into the Atlantic. S. lat. 17° 25'.

JACO, in Ornithology. See Pettaetus Erithacus.

JACOB, in Scripture History, the son of Isaac and Rebecca, was born in the year B. C. 1836. He was twin-brother of Esau (see Gen. xxv. 25.), of a meek peaceable disposition, domestic in his habits, inclined to a pastoral life, and the favourite of his mother; whereas, Esau was of a more fierce and turbulent temper, fond of hunting, and, in consequence of his masculine active spirit, the object of his father's partial affection. Jacob derived his name from the manner of his birth, as he came into the world holding his brother's heel, which, in Hebrew, is exprest by נָעַף, whence נָעַף, he supplanted, a term indicating some events that occurred in the progress of his years, and of which we have already given a brief account under the article Esau. It is needful minutely to detail the particulars of his future history, as they are recited in the book of Genesis, to which the reader is referred. Here we find, that in order to avoid the threatened effects of his brother's displeasure, incurred as we have already related under the article Esau; Jacob was sent by his mother to her brother Laban. In his journey he had a vision of a peculiar nature, which brightened his prospects, and induced him to form pious and laudable resolutions. On his arrival at Padan-Aram, he was hospitably received by his uncle Laban; and in a little while he conceived an affection for Rachael, his youngest daughter. In order to obtain Laban's consent to their marriage, he agreed to serve him seven years; but at the close of this period of service, Leah, the elder sister, was substituted for Rachael; and he determined to return with his wives and children, and the property he had acquired, to his own country. Availing himself of an opportunity which Laban's absence afforded, he prepared for his journey; and he had proceeded so far before his departure was known, that Laban was seven days in pursuing him before he could overtake him. Upon their interview on mount Gilead, Laban remonstrated and Jacob justified the measure which he had adopted. Rachael, however, before her departure, had contrived to purloin her father's teraphim (which see); and Laban, in his remonstrance with Jacob, complained of the robbery. Jacob, unapprized of the fact, contented to an examination of every tent, and declared that the individual, who was guilty of the robbery, should be put to death. Rachael contrived to elude the search; and Laban, apprehending that his charge was unsafe, inclined to measures of conciliation. Accordingly, he proceeded to Jacob terms of alliance, and that a monument should be erected as a testimony of it to future ages. Jacob acquiesced: a pile of stones was reared, called by Laban, in the Syrian tongue, Jargar-Sahaddutha, and by Jacob, in Hebrew, Gilced; both signifying the leap of witnesses. The treaty was concluded with a sacrifice and a feast; and Laban, having embraced and blessed Jacob and his family, set out on his return to Padan-Aram. Jacob, as he pursued his journey, began to entertain apprehensions of the unpunished repentence of his brother Esau; and notwithstanding the conciliatory measures he had adopted, he soon found that his brother was advancing to meet him with an armed force, and with seeming purposes of hostility. Having recommended himself by an act of devotion to the divine protection, he prepared a coffy present for his brother. At this time he was favoured with a prophetic vision, which served to allay his fears and to animate his resolution; and from a circumstance that occurred on this occasion, he obtained the name of"Israel," signifying a man who has prevailed with God; and this became afterwards the name of his posterity. Having joined his family after this vision, he advanced to meet his brother, who received him in the most kind and affectionate manner, and invited him to settle in his neighbourhood. Jacob, however, could not easily...
dissipate his apprehensions of danger, and chose rather to take up his abode near Schechen, where he purchased ground on which he built an altar to the Lord. A circumstance of a very distressing kind occurred, for an account of which we refer to the history, which made it necessary for Jacob to remove from the vicinity of Schechen; and whilst he was deliberating whither to direct his course, he was instructed to erect an altar to God at Bethel, a place where he had received early assurances of the divine protection and favour. Having erected an altar at this place, he set out on his journey to his father; but in the way he was severely afflicted by the loss of his beloved wife Rachel, who died in childbirth of her son Benjamin. Soon afterwards he arrived at Haman, and continued there until his father’s death. At this time Joseph, being about 17 years of age, became the object of jealousy to his brethren; who, meditating his destruction, determined at length to sell him to a troop of Ishmaelites, and to feign a story, with which they imposed upon the afflicted father, of his having been torn to pieces by some wild beast. After the lapse of some years, Joseph received the consolatory news of Joseph’s being still alive, and in a station of high honour and power at the court of Pharaoh. (See Joseph.) The news, we may well imagine, transported him beyond measure, and he fainted in the arms of his sons who communicated it. As soon as he could be persuaded that the report was true, and found himself surrounded by the presents of his son, and by the chariots of Egypt, which were to convey him and his family thither, he prepared for his journey, and in his way stopped at Beersheba, to offer sacrifices to God, thus expressing his gratitude and his desires of continued protection and blessing. Having received assurances of divine favour, he purified his journey with pleasure; and, as he approached the borders of Egypt, he received a message from Joseph, requesting him to meet him in the land of Goshen, situated between the Red sea and the Nile, which was a fruitful territory, and adapted to his pastoral life. The interview between the patriarch and his son Joseph is best conceived by a mind of virtuous sensibility. Having obtained leave of Pharaoh to settle in the land of Goshen, Joseph conducted his father and family thither; and here they prospered and multiplied. Jacob lived 17 years in Egypt; and when he apprehended that his life was drawing to a close, he obtained a promise from Joseph that his remains should be carried to Canaan, and deposited with those of his progenitors, Abraham and Isaac, in the case of the field of Machpelah, which Abraham had purchased. When he was dying, he adopted the two sons of Joseph, Manasseh and Ephraim, as his own; declaring, that in the division of the promised land they were to receive a double lot, and to be considered as the heads of two distinct tribes. Having delivered to his sons, who were collected round him, his dying predictions of the events that should happen to their several descendants in future times, and which exactly corresponded to the patriarch’s declarations, Jacob expired, at the age of 147 years, in the year B.C. 1689. Joseph faithfully fulfilled his promises with respect to the burial of his father; and Pharaoh testified his respect for Joseph by contributing in various ways to the pomp of the funeral procession. After having deposited the remains of their father in the cave of Machpelah, Jacob’s sons returned to Egypt, where they and their posterity remained till the time of the Exod. See Exodus. Genesis, ch. xxx.—4. Anc. Un. Hist. vol. ii. p. 248. &c. &c. Calmet’s Dict. Bib. art. Jacob.

Jacob, John, in Biographia, was a native of Zulphah, and in the year 1641 he filled the post of principal joiner to the king of Peru. He was celebrated for his skill in mechanism, and was author of many useful inventions. Having an opportunity of visiting Europe, he formed a complete idea of the art of printing, and upon his return to Isfahan he succeeded in erecting a press, and cut for himself matrices for the necessary types. The first speciments of his typographical art were in the Armenian language, and consisted of the epitaphs of St. Paul, and the seven penitentary psalms. He would have proceeded with the other parts of the bible, but his profligates alarmed the copyists, who excused such a clamour against him that he was obliged to lay aside the undertaking. He was a Christian in religion; but on account of his very extraordinary talents he was permitted to hold a post which was never before occupied but by a Malmester. His sovereign would gladly have enrolled him among the followers of the prophet, but no offers of preferment, however tempting, could prevail on him to renounce Christianity. Moreni.

Jacob, Henry, celebrated as the founder of the first independent or congregational church in England, was a native of Kent, and received his academical education at St. Mary’s hall, Oxford. Having entered into holy orders, he was made precentor of Corpus Christi college, and afterwards obtained the benefice of Cheriton in Kent. In the year 1624 he published “A Sermon taken out of God’s Word, and the best of human Testimonies, proving the Necessity of Reforming our Churches of England.” The publication of this, and of another work, against what was falsely called “learned preaching,” drew down upon him the persecution of bishop Bancroft, and to avoid his wrath he fled to Holland. At Leyden he met with Mr. Robinson, with whom he had frequent conferences, and became a convert to the Brownist principles, since known by the name of Independency. In Holland he published several treatises, and upon his return he avowed a design of setting up a separate congregation upon the model of those in Holland. This, in a short time, he carried into effect, and thus laid the foundation of the first independent congregational church in England. He was elected pastor of the church, and continued with his people till the year 1624, when, being desirous of entering on a more enlarged sphere of usefulness, he went to Virginia, where he soon afterwards died. He was author of many publications which were highly esteemed in his day. Neat’s Hist. Puritans.

Jacob, Henry, son of the preceding, was born in the year 1609. He received the greater part of his education at Leyden, and made a wonderful progress in the study of the Hebrew and oriental learned languages. He was appointed first by the earl of Pembroke, and then by archbishop Laud, by the influence of the latter he was appointed “foculus grammaticus” in Merton college, a post which had not been occupied for more than a century, and the duties of which required him to be reader of philosophy to the juniors. He became fellow of his college, and acted some time as amanuensis to Mr. Selden. In 1648 he was expelled from his fellowship and college by the parliamentary visitors; and being delirious with the news of celibacy he came to London, where his friend Mr. Selden contributed to his support. He was never an economist either with regard to his little property or his health, and by intense application to his studies he died, at Canterbury, at the early age of 44. He left behind him many very learned pieces, particularly “Greek et Latina Poemata.” Gen. Biggs.

Jacob, a performer on the establishment of the Royal Academy at Paris, a fiddler, on the violin, of Gavignac, who likewise taught that instrument, according to the principles of his master, by which he acquired reputation. He published, in 1769, a new musical grammar, in which he wrote down
JACOB, St. in Geography, a town of the duchy of Sestia; seven miles W. of Frudberg.—Also, a town of Sestia; six miles N.E. of Murburg.—Also, a town of Tyrol; eight miles S of Landeck.—Also, a town of Sweden, in the government of Abo; 10 miles E. of Abo.

JACOB'S Creek, an eastern water of Yonghigany river, in Wellmorland county, Pennsylvania. Six miles W. to Monongahla river there is a carrying place from the Yonghi- gany, opposite to the mouth of this creek.

JACOB'S Ladder, in Botany. See POLLENION.

JACOB'S Staff, a mathematical instrument for taking heights and distances; the same with the cross-staff.

JACOBEA, in Botany. See SENECIO.

JACOBEAN LILY, See Amorium Formosum.

The name is given by the Spaniards, because this flower resembles, in size, colour and shape, the red croq worn by the knights of the order of St. James, embroidered on their habits, as may be seen by some of their portraits brought into this country.

JACOBEA STRUM. See OTHONNA.

JACOBEOIDES. See OTHONNA.

JACOBazzi, DOMINIC, in Biography, an Italian cardinal, was born at Rome in the year 1442. Having fixed upon the ecclesiastical life, he applied himself to the study of the canon law and theology, and became so eminent for his proficiency in these sciences, and for his talents as a man of business, that he was employed by pope Sixtus IV., and five of his successors, in the management of several important affairs. He rose rapidly in the church; by pope Julius II. he was made vicar of Rome, and president of the university in that city; he was likewise put in possession of several bishoprics, and at length, in the year 1517, he was elevated to the rank of cardinal by pope Leo X. He died about the year 1527, when he was 84 years of age. He was author of "A Treatise concerning the Councils," which was originally published at Rome in 1538, in folio. It forms the 18th volume of father Labe's "Collectio Maxima Conciliorum," and renders that collection extremely valuable.

JACOBIN, in Ornithology. See LOMA MELocha.

JACOBINE, the name of a particular species of pigeon, called by Moore the columba cyperia cypris. (See COLUMBA CYPRIA.) It is generally called the jack, for shortness. It is, when genuine and of the true breed, the finest of all pigeons. It has a range of feathers inveterate quite over the hinder part of its head, and reaching down on each side of the neck to the shoulders of the wings, which forms a kind of friar's hood, from whence the bird has its name. This species has also a short bill, and a nearly eye. The colour is various in the feathers; there are reds, yellows, blues, blacks, and mottles; but whatever is the general colour, the head, tail, and flight, are white. Some pigeons of this species are feather-legged, others are not.

JACOBINS, a name given in France to the religious who follow the rule of St. Dominick, on account of their principal convent, which is near the gate of St. James, in Latin Jacob- bus, at Paris; and which, before they came possesst of it in the year 1218, was an hospital of pilgrims, dedicated to the said saint. (See DOMINICK.) Others maintain, that they have been called Jacobins ever since they were established in Italy, because they pretended to imitate the lives of the apostles.

They are also called friars predicanst, or preaching friars.

JACOBITES, in Ecclesiastical History, a sect of heretics, who were an ancient branch of the Eunyrians, and are still subsisting in the Levant.

They were so called from Jacobus, James, of Syria, called Albardari, or Baradari, who was one of the heads of the Monophysites, or sectaries who owned but one nature in Jesus Christ.

This poor monk revived the cause of the Monophysites by his activity and diligence; and when he died bishop of Edessa, A.D. 588, he left this sect in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. The laborious efforts of Jacob were crowned in Egypt, and the adjacent countries, by theodosus, bishop of Alexandria.

The Monophysites were a sect of vast extent, comprehending the Armenians, Orontes, and Abyssinians; and the denomination of Jacobites is commonly used in an extensive sense, as comprehending all of them, except the Armenians; but it more strictly and properly belongs to those Arabic Monophysites, of which Jacob Albardari was the restorer and chief. All the patriarchs of the Jacobites assume the denomination of Igiatus.

As to their faith, all the Monophysites, both Jacobites and others, follow the doctrine of Dioclesius touching the unity of nature and person in Jesus Christ. See MONOPHYSITES.

JACOBITES, in England, is a term of reproach belted on such persons as disallow of the revolution by king William, and still assert the rights, and adhere to the interests of the abdicated king James, and his line.

JACOBS, LUCAS, in Biography, a painter, born at Leyden, and therefore commonly known by the name of Lucas Van Leyden. In the year 1494 he made the enter of life, and as he grew up was instructed by his father, Hugh Jacobs, in the art of painting. Afterwards he became the pupil of Cornelius Engelenbruch, and had acquired considerable reputation as a painter, and also as an engraver, when he arrived at the age of manhood.

His style is that of the dry Gothic school of Germany, of which Albert Durer is the leader; close upon whom followed Jacobs, with nearly as much merit as a painter, though not his equal by far in invention. The attempt to copy the model closely is in the works of the latter as evident as in those of the former, and his draperies have the same character. Both are imperfect and meagre in lines; but sometimes, where they copied the large flowing draperies of the church, they are broad and have much majesty. His feeling of expression is of a low and vulgar kind, and oftentimes more grimacy; but it must be acknowledged that he and Albert were far above their contemporaries in Germany.

The works of this master are numerous; but he is perhaps better known by his prints, engraved by himself with great ingenuity, from a great number of his pictures in Leyden, Amsterdam, Vienna, &c. &c.

He died in 1553, at the age of 39.

JACOBSHAGEN, in Geography, a town of Pomerania; 16 miles E. of Stargard. N. lat. 53° 25'. E. long. 15° 30'.

JACOBSON, John Charles Gottfried, in Biography, was born at Elbingen in 1736. He studied at Leipsic, but in consequence of an unfortunate duel he was obliged to leave that.
that place, and entered into the service of the elector of Saxony. He afterwards enlisted in a regiment of infantry at Berlin, and during a two years' residence in that city he diligently frequented the different manufactories and workshops, and between the years 1773 and 1756 published his "Description of all the Cloth Manufactories in Germany," in four volumes octavo. He was indefatigable in his pursuits, and besides his own publications he assisted Sprengel in his "Collection of the Arts and Handicrafts," and Nicolaï in his "Description of Berlin." In 1778 he was actively engaged in military affairs, but after the campaign of this year he obtained a discharge, and began his "Technological Dictionary of all Useful Trades, Arts, Manufactures, &c." which was published in parts between the years 1781 and 1784. In the latter year he was appointed inspector of all the royal manufactories in the kingdom of Prussia; he died in 1789. He was the author of a "Description of all the Linen, Cotton, and Woollen Manufactures in the Prussian States," in 4 vols., and he had begun a "Compendium of Technology," when death put an end to his labours. Gen. Biog.

JACOBSTADT, in Geography, a sea-port town of Sweden, in the government of Väst, with a convenient port. N. lat. 56° 41' E. long. 22° 36'.

JACOBUS, a gold coin, worth twenty-five shillings; so called from King James the First of England, whose reign it was struck. We usually distinguish two kinds of Jacobus, the old and the new; the former valued at twenty-five shillings, weighing six penny-weights ten grains; the latter, called also Carolus, valued at twenty-three shillings; in weight five penny-weights twenty grains.

JACOPONE DA TOUT, in Biography, an Italian poet of the 13th century, was born at Todli, of the noble family of Benedetti, or Benedettoni. He was brought up to the profession of the law, in which he practised, obtained a fortune, and lived in every respect as a man of the world. A furious accident which befall his wife, and occasioned her death, led him to reflection, and he immediately devoted himself to religion. He entered the order of the Franciscans; to receive the humiliation of contempt he counterfeited folly, and succeeded so well, that his baptismal name of Jacopo was changed into the nick-name of Jacopone. The rigour of his superiors purified his own voluntary mortifications, and for a flight offence he was thrust into a noisome dungeon, where he is said to have composed one of his most rapturous canticles of divine love. He underwent greater sufferings from the repentment of pope Boniface VIII., on account of some reflections thrown out respecting the evils brought on the church by that pontiff. He was closely imprisoned, and allowed no other subsistence than bread and water. He suffered his liberation but three years, and died in 1366. His "Spiritual Canticles" have given him a place among the Italian poets. Of this work the best edition is that of Venice, in 1617. Moroni.

JACPOE, in Geography, a town on the W. coast of the island of Borneo. S. lat. 0° 14'. E. long. 109° 21'.

JACQUELOT, ISAAC, in Biography, was born at Vassy, in Champagne, in the year 1647. He was educated for the ministry and as soon as he had arrived at man's estate he was appointed his father's colleague in the church of his native place. After the revocation of the edict of Nantz he retired to Heidelberg, and from thence he removed to the Hague. His talents as a preacher acquired for him a high reputation, and he was solicited by the king of Prussia to become his minifter at Berlin; to which he readily acceded, and enjoyed a handsome pension from his majesty till his death in 1758. He was author of many works, among which are "Differtations on the Excellency of God;" "Differtations on the Messiah;" and "A Treatise on the Inspiration of the Sacred Books;" He wrote and published "A Criciticism on the Picture of Socinianism," written by Junius, which exposed M. Jacquelot to a bitter persecution.

JACQUES, FRER (Friar James), whose surname was Baulot, or Beaulieu, a celebrated lithomift, and a man of singular character, was born, in 1631, at a village in Franche-Comté, where his father was a poor labourer. At the age of sixteen he was seized with an inclination to travel. The education, which he had received, did not extend beyond writing and reading; but he had an ardent desire for other knowledge, and a propensity, which he felt for the practice of surgery, was put in the way of gratification, by himself becoming a patient in the hospital of his province. During his convalescence, he applied himself with great avidity to affording the sick, and learned to bleed. He soon afterwards enlisted in a regiment of cavalry, in which he served five years, and became acquainted with an Italian empirical surgeon, named Pauloni, who had become famous for cutting for the stone, and curing ruptures. Having procured his discharge, at the age of twenty-one, Jacques attached himself to this empiric, and travelled with him five or six years, in various countries, as an affluent. At length feeling himself equal to undertake the practice without a director, he quitted Pauloni, and began to act for himself in the villages and country towns of Provence, taking no more remuneration for his services, than just sufficed for his humble maintenance. After having practised his art eight or ten years, he put on a monastic habit, in 1650, or 1691, but not of any particular religious order, and took the name of free Jacques, by which he was ever afterwards distinguished. He now visited the larger towns; especially Marseilles, and went also into other provinces, where he chiefly operated upon the poor; but, among the persons of rank whom he cut, was a canon of Paris, who recommended him to visit the metropolis, and gave him letters of introduction. He arrived at Paris in August 1667, and was ordered to perform his operation on the dead body in the presence of the physicians and surgeons of the Hôtel-Dieu. But although one or two of these officers gave a preference to his operation, prejudice and envy prevailed, and he was not allowed to practise it on the living body. He, therefore, quitted Paris in October of the same year, and went to Fontainebleau, the residence of the court, where the suffrages of his operation, in the presence of the principal medical men, obtained him a reputation, which led to a second visit to Paris; where he is said to have been unsuccessful in a large proportion of his operations, and was taxed with extreme ignorance of anatomy, as well as of the art of surgery in general, so that he refused, it was alleged, to pay much attention to the wound, saying, that "it was sufficient that he had removed the stone; God would heal the patient." Time and experience, however, taught him better; and he employed proper dressings and treatment. His name spread throughout Europe as the most successful lithomist of his time; and between the years 1688 and 1714, he visited Holland, Geneva, Flanders, and the principal cities, performing an immense number of operations with various successes. When at Paris, in 1703, he performed his operation on the marshal de Logres, who died on the following day, and he quitted that city in some disgrace, resolved never to return. He was much honoured by the magistrates of Amsterdam, who caused his portrait to be engraved, with the inscription, "Frater Jacobus de Beaulieu, Anachoretæ Burgundii, Lithotomus omnium Europæorum perfectissimus." and above it, this motto, as a justification of some of his failures,
failures,—"Quia non omnes convalescent, non idcirco nulla medicina est."—The celebrated surgeon and anatomist, Rau, opposed him, however, with acrimony; but did not refuse to borrow from him his method, which, with some improvements, constituted the lateral operation, afterwards brought to perfection in England by Cheffelden. In the course of his travels, Frere Jacques was called to Vienna to be consulted for the emperor Joseph; and at Rome, he was received with great honour by the pope. But tired at length with wandering about, he founded a native village: his parents were dead; and, having distributed from money among his nephews, he chose a quiet retreat near Befançon, with a view of spending his days in retirement and tranquillity. And after a sojourn of a few weeks, he died, in December 1714, at the age of sixty-nine, with all the tokens of sincere piety. Frere Jacques, though in some measure chargeable with the temperity of ignorance, was a man of genius and of an elevated mind, and deserves to rank among the improvers of an useful art. He published an account of his method of operating, in 1702, in a pamphlet of eight pages; and it was reprinted by M. Morand in the second part of his "Opera fere." Elov. Dict. Hift.—Gen. Bioth.

JACQUIER, FRANÇAIS, a very learned ecclesiastic and mathematician, was born at Vitry, near Paris, in 1711, and died at Rome in 1788. He was one of the editors of what is generally known in this country as "The Jefuits' Edition of Sir Isaac Newton's Principia." This edition, which was published in four thin volumes in 1740, in the year 1762, is illustrated with a perpetual commentary, for the benefit, as the editors avow, neither of the very learned, nor of those who are wholly unskilled in mathematical science. Jacquier was author of several works written in the Italian language.

Gen. Ch. Cal. Perianth inferior, of five roundish, convexe, permanent leaves. Cor. of one petal; tube bell-shaped, inflated, longer than the calyx; limb in ten roundish segments, of which the five inner ones are shortened. Stam. Filaments five, awl-shaped, inserted into the receptacle; anthers arrow-shaped. Fil. German superior, ovate; style the length of the flans; stigma capitulate. Pet. Berry roundish, pointed, of one cell. Seed solitary, roundish, cartilaginous.

Obit. The German contains the rudiments of several seeds, one of which only, for the most part, comes to perfection. Hence the embryo, naturally erect, becomes transverse from the altered position of the seed in ripening. See Brown's Prodr. v. 1. 523.

Five furred species of Jacquinia are defined by Willdenow, but of these one is indicated by Mr. Brown as a new genus, belonging to a very different order, the Rubiaceae. This is J. venosa of Swartz's Predominus, omitted either by accident or delign, in his Flora Ind. Occid. The place of this, however, is supplied by a new species from the second edition of the Hortus Kewensis. They are all shrubby or arboreous, with rigid, smooth, entire, scattered leaves on short flakes, each with a pair of minute, awl-shaped, intrapetallaceous, deciduous filipulas, not always discernible. Flowers terminal, racemose or solitary, white, yellow, or orange-coloured, on smooth flakes.

1. J. arborea. Vahl. Eclog. Amer. falc. t. 26. Willd. n. 1.—Leaves obovate, somewhat wedge-shaped. Branches even; the lowermost quadrature; upper ones forked. Found by Mr. Ryan in the island of Montserrat, on the face of one place only, near the road called New Windward. A tree from four to twenty feet high, the trunk from six to eight inches thick, the branches scarcely swelling under their subdivisions, in which character and its greater size only it differs from the following, and they ought surely to be considered as mere varieties.

2. J. arnolitica. Linn. Sp. Pl. 272. Jacq. Amer. 53. t. 39.—Leaves obovate, somewhat wedge-shaped. Branches swelling under their subdivisions; whorled below; forked above. Clusters many-flowered.—Native of the West Indies. A handsome flower, seldom more than four or five feet high. Leaves two inches long, emarginate, sometimes with a minute point. Flowers about 20 in a cluster, the size of hylot of the valley, white, smelling like jasmine. Berry as big as a pea, reddish orange. The Indians are said by Jacquin to make bracelets of the seeds, whence the specific name, and the leaves to intoxicate fish if thrown into the water.

3. J. aurantia. Ait. Hort. Kew. ed. 2. v. 2. 6.—Leaves obovate or lanceolate, with spiny points. Clusters of few flowers—Discovered in the Sandwich islands by Mr. Archibald Menzies, by whom it was introduced into the Kew garden in 1766. It is kept in the hothouse and flowers most part of the summer. The upper leaves of each branch resemble those of the two foregoing, but the lower ones are smaller and almost lanceolate; every one of them is tipped with a rigid spine. The branches and flakes are slightly downy. Flowers orange-coloured, only three in the cluster of the only specimen we have seen, which is preferred in the Bankfield herbarium.

4. J. rufifolia. Linn. Sp. Pl. 271. Jacq. Amer. 54. Ait. Hor. Kew. ed. 2. v. 2. 6. (Rufus folius rufellatiss. Eul. Elh. v. 1. 148. t. 125. f. 149.)—Leaves all lanceolate, with spiny points. Flower-flakes simple.—Native of South America. Found by Jacquin in mountainous woods at the Havanah, flowering in January and February. A rigid flower, three feet high; with narrow, coriaceous, spiny-pointed leaves, whose form is like the lower leaves of the species last mentioned. The flakes are single-flowered, recurved as the fruit ripens. A large variety, as it appears to be, of this species, received by Miller from Carthagena, and called by that author in his Dictionary Rufus flavifolius, is preferred in the Bankfield herbarium. Its larger leaves somewhat approach those of the aurantia, but the flower-flakes are simple.

5. J. linaria. Linn. Sp. Pl. 272. Jacq. Amer. 54. t. 30. f. 1.—Leaves linear, with spiny points. Flower-flakes simple, reflexed.—Native of the sea-shore near Port-au-Prince in Hispaniola, bearing flowers and fruit in January, Jacquin. Much smaller than any of the foregoing, with leaves feebly more than an inch long. Flowers small, white, inodorous, on slender reflexed flakes.

JACRAH, in Geography, a town of Bengal; 35 miles S. of Burdwan.

JACTITATION OF MARRIAGE. See Marriage.

JACULATOR, or SHOOTING-FISH, in Ichthyology, is a species.
a species of \textit{chetodes} in the Linnean system, or the \textit{Charadon Regius}, which fee.

\textbf{JACULGON}, in Geography, a town of Hindooftan, in Dowlatabad; 18 miles S. of Oudighir.

\textbf{JACULUM}, or \textbf{JACULS}, in Zoology, the name of a species of serpents, (the \textit{Anguis Jaculus},) found in Rhodes, and some other places, and more usually called \textit{Aenopus}; which fee. It is found in Egypt, with the abdominal scales somewhat broader.

\textbf{JACULUS}. See \textit{Diptus Jaculus}.

\textbf{JACUPEMA}, in Ornithology, the name of a Brazilian bird of the pheasant kind, nearly as large as the common European hens. Its feet are of a fine red; it is very well tilled foot, and is easily kept tame. It has its name from the uncle it makes, which is, \textit{jacu}, \textit{jaen}, \textit{jaen}. Margrave. See \textit{Penelope crigula}.

\textbf{JACURSO}, in Geography, a town of Naples, in Calabria Ultra; 8 miles W. of Squillace.

\textbf{JACURUTU}, in Ornithology, the \textit{Bubo Magellanicus}. See \textit{Strix Bubo}.

\textbf{JACUSI}, in Geography, a town of Japan, in the island of Niphon; 25 miles N. E. of Achilt.

\textbf{JACT}, in the \textit{Natural History} of the \textit{Arabians}, is generally supposed to be the name of the ruby only; and it is owing to this, that among the gems used by the Arabian physicians in medicine, the ruby is supposed to have been most of all in esteem, as the name jacut oftener occurs in their writings than that of any other gems.

\textbf{JACTU-AGA}, is the name of an officer in the court of the grand signior. He is one of two eunuchs who have the care of the treasure.

\textbf{JACZIN}, in Geography, a town of Poland, in Galicia; 35 miles S. W. of Halicz.

\textbf{JACZINOW}, a town of Galicia; 52 miles S. of Halicz.

\textbf{JADDJSES}, is the name of an inferior order of priests in Ceylon, who have the care of the chapels appropriated to the gods, who form a third order of gods among these idolaters. These priests are applied to by the people in a time of disease or calamity, who offer a cock on their behalf to appease the anger of the demons.

\textbf{JADE}, in \textit{Natural History}. See \textit{Nephritic Stone}.

\textbf{JADEL}, in Geography, a town of Affatic Turkey, in the province of Diarbakir; 20 miles N.W. of Rabbah.

\textbf{JADERA}, in \textit{Ancient Geography}, a town and colony of Liburnia, placed by Pliny 160 miles from Pola. We find references to it in the medals of Claudius and Julian.

\textbf{JADEVAR}, in Geography, a town of Hindooftan, in Vifapur; 15 miles E. of Raibang.

\textbf{JADEREM}, or \textbf{JACEREM}, a town of Peria, in the province of Chorfan. N. lat. 56° 23'. E. long. 55° 42'.

\textbf{JADAPOUR}, a town of Bengal; 33 miles S. S.E. of Moorhedabad.

\textbf{JADISPOUR}, a town of Hindooftan, in Bahar; 21 miles W. of Arrah.

\textbf{JADO}, a town of Japan, in the island of Niphon; 5 miles S.E. of Meaco.

\textbf{JADREKA}, in Ornithology. See \textit{Scolopax Linnaei}.

\textbf{JADUNAPOUR}, in Geography, a town of Hindooftan, in Bahar, on the Sonne; 20 miles W.S. of Rotagur.

\textbf{JALGERSPREIS}, a town of Denmark, in the island of Zealand; 22 miles N.W. of Copenhagen.

\textbf{JAEL}, a town of Hindooftan, in the circuit of Nagore; 16 miles N. E. of Nagore.

\textbf{JAEN}, a province of Spain, from which the king of Spain takes the title of king of Jaen, whence it is called a kingdom, and having been a kingdom in the time of the Moors, till it was annexed to the crown of Castile: it is now comprehended under the government of Andalusia, and forms one of its divisions. It is about 60 miles from N. to S. and about as much from E. to W., itself mountainous and surrounded with mountains, which afford mines of lead, copper, and silver, and which separate it from the kingdoms of Cordova, Toledo, Murcia, and Granada. The river Guadalquivir divides it from the kingdom of Seville. The valleys of this province are merely such as have been formed by torrents of water; and the decomposition of the hills, not contiguous or connected, have at different periods produced these gaps and paffes, which now form the roads in this petty kingdom, once the domain of a Moorish chieftain, and for a long period the theatre of chivalry, honour, and love. In the centre of this rugged kingdom, about 2° of a league from the town of Linares, is a small plain situated in the most elevated part of the country, which affords an extensive prospect, comprehending Jaen the capital, as well as Andojar, Baeza and Ubeda. The hills at the extremity of this place are pierced like a sieve, with innumerable shafts and excavations, supposed to be the work of the Moors, from which they supplied the neighbouring states with silver, copper, and lead. The common or wild eucalyptus is so common here, that the whole kingdom might be studded with it; there is also plenty of game. The principal towns of this small kingdom are Jaen, Baeza, Ubeda, Caceros, and Calzona.

\textbf{JAEW}, the capital of the above kingdom, is laid by force to have been the Onigi of Pliny, and the Oringi of Livy, and, according to others, the Menteia of the Romans. It is situated at the foot of a mountain of mixed marl, at the top of which the ruins of its ancient caffle are visible, a league from the river Guadalquivir, and two from the Guadalquivir. It is surrounded by walls, flanked with towers; contains some squares, one of which is spacious, and is formed by pleasant houses. It is well supplied with water, which is distributed by fountains in the squares, streets and houses. This city is the see of a bishop, suffragan of the archbishop of Toledo, its diocese contains two cathedral chapters, two collegiate chapters, seven arch-priests, and 438 parish churches. Besides the cathedral, which is a noble structure, and parish churches, Jaen has a great number of monasteries and nunneries, and two hospitals. The chapter of the cathedral is composed of eight dignitaries, 21 canons, 21 prebendaries, and 39 priests who serve the church. This city is the residence of the intendent of the province; it has a criminal judge, and a lord mayor for the administration of justice, a municipality composed of a determinate number of regidors, a board of economy, and a population of about 36,000 persons. Jaen was taken from the Moors by Ferdinand II. king of Castile, in 1242. It was formerly rich and commercial, and had a great number of silk manufactories; but these became almost extinct at the end of the 16th and beginning of the 17th century. An attempt was made to revive them about the middle of the 18th century; but few of them are now remaining. The environs of Jaen are extremely agreeable, abounding with delightful fertile valleys, and furnishing great quantities of corn hemp, flax, paille, and exquisite fruits. The lands belonging to the town yield the same productions, in still greater plenty they are particularly planted with trees of every kind, and as there is no deficiency of mulberry trees, the silk-worm is reared; but it is an object very much neglected. 45 miles N. of Cordova. N. lat. 37° 53'. W. long. 3° 51'.

\textbf{Jaen de Bracamoros}, a province of South America, in the viceroyalty of New Granada. It is the most southern of the viceroyalty, and was subdued by Pizarro about the year
year 1540. In the mountains is found some gold; and the plains produce cotton, excellent chocolate, and tobacco.

Aen et Gratamoros is also the name of a town, the capital of the above province, which was founded in the year 1540 by Diego Palolino. It is situated in the jurisdiction of Chac-Inga, on the N. shore of the river Chinchipe, at its confluence with the Maranon, and is the residence of the governor. It lies in about 5° 25' S. lat. and its longitude is nearly that of Quito. It contains between 3 and 4000 inhabitants, who are for the most part Mefitzos, with some Indians, but very few Spaniards.

JAEPOUR. See JVENAGUR.

JAEERSBORG, a town of Denmark, in the island of Zealand; 5 miles N.N.W. of Copenhaegn.

JAFAT, a territory of Arabia, surrounded by Aden, some part of the Imam's dominions, and the extensive province of Hadramaut. It is fertile, and abounds particularly in coffee and cattle. It was formerly under the dominion of the Imam; but in the end of the 17th century the inhabitants revolted, and became independent. They are governed at present by three sovereign princes, who have conquered also a part of Hadramaut. These princes are, the sultan of Reffes, who resides at Medjeba, the sultan of Mofaka, who takes his title from the place of his residence, and the sultan of Kara, who resides in a castle upon the mountain of Kara. One of these futans of Jaff alikewise possesses Schubar, a sea-port town, from which incense, inferior in quality to that of India, is exported. Niebuhr.

JAFATIN ISLANDS, a cluster of small islands in the Red Sea, near the coast of Egypt. N. lat. 27° 40'. E. long. 33° 50'.

JAFERI, a town of Persia, in Chorasen; 75 miles N.N.W. of Badis.

JAFNA, YAFFA, YAPA, or YAFFE, the ancient Joppa, was formerly a considerable sea-port on the Mediterranean, and the only port which the Jews had on that sea. It was seated on a high hill, which commanded a full prospect of the sea on one side, and of a fertile country on the other. On the S. it had the town of Jamiia, on the N. Cefares Palestine, and on the E. Rama or Ramula. During the holy war, this city, so often mentioned both in the Old and New Testament, was entirely ruined, that it had scarcely any buildings left besides the old castle, situated on an eminence above it, and another near the sea. The present town has been nearly rebuilt with stone, but on account of the inequality of its situation the streets are paved in steps. It is walled, and has two principal gates and a smaller one; the latter and one of the former yet remain; the other is shut up. It is commanded by an eminence on the N. within a mudzet, where Ali Bey, when he besieged it, pitched his camp. Although it has a good wharf, ships cannot come up to it; nor has it any part of a secure place of anchorage. This port, which is formed by a pier, and at present choked up, might be cleared out, and made to contain vessels of 500 tons burden each. At present ships are obliged to cast anchor out at sea, at nearly a league's distance from the shore; where they are by no means safe, the bottom being a bank of rock and coral, which extends as far as Gaza. Yafa is the port at which the rice sent from Damietta to Jerusalem, the merchandise for a small factory at Ramla, and the commodities from the various ports on the coast of Syria, are landed. Here also the pilgrims from the Morea and Confaitantinople arrive; and here the spun cottons of Palestine, and other articles of trade, conveyed by sea, along the coast, are shipped. Although in its present state it does not deserve mention as a sea-port, or place of strength, it is capable of being made one of the most important on the coast, on account of two springs of fresh water which are within its walls, on the sea-shore, and which enabled it to make an obstinate resistance during the late wars. The air, formerly deemed inhospitable, has, by the draining of some adjacent marshes, been rendered perfectly healthy; and before the two late sieges, it was one of the most agreeable towns on the coast. Its environs were a continued forest of orange and lemon trees, citrons and palms, which here first begin to bear good fruit. The country at a greater distance abounded with olive trees as large as walnut trees; but in the sieges undertaken by Ali Bey and his successor Mahomed Abu-dhabal, the Mamoulus cut them down and used them for firewood. It has thus lost its greatest convenience and ornament; but it was impossible to deprive it of the rivulets that water its gardens, and nourish the young suckers, which have already begun to shoot. This town has three small convents of Christians, Armenian, Greek, and Roman Catholic, and a few Jews. Yafa is one of the three appanages, or "Melkana," into which Palestine is divided, the other two being Lod and Gaza. The former belongs to the Walda, or Sultana-Mother; and is held by an Aga, who pays to her 120 purses. For this he receives the whole miri and poll-tax of the town, and some adjacent villages. But the chief part of his revenue arises from the custom-house, as he receives all the duties on imports and exports. The government is now mild; and the population, gradually increasing, may be estimated at 6,000 souls. Jaffa, in the year 1799, was taken by the French, though not without considerable difficulty and bloodshed, but they held possession only 40 days. According to Sir R. Wilson the conquest was followed by a massacre of 380 prisoners, four days after the surrender of the town; and he informs us that 580 French soldiers, sick in the hospital, were poisoned with opium by command of the French general Bonaparte; 40 miles S. of Acre, and 40 miles N. of Gaza. N. lat. 32° 2'. E. long. 34° 53'. Volney's Travels, vol. ii. Brown's Travels, p. 359.

JAFIERABAD, a town of Hindooftan, in the country of Berar, and cirec of Aurungabad, 40 miles N.N.E. of Aurungabad. N. lat. 20° 22'. E. long. 76° 25'.—Alfo, a town of Hindooftan, on the coast of Goozert, and next to Du, a place of the great trade on this coast. The town is surrounded by a wall for its defence. In a river near this town are found very large oysters. N. lat. 20° 56'. E. long. 70° 36'.—Alfo, a town of Bengal; 6 miles N.W. of Ilamabad. —Alfo, a town of Oude; 7 miles S.E. of Hajoypour.

JAFFIERUNGE, a town of Bengal; 40 miles E.S.E. of Dacca.

JAFFNA, the capital of the district of Jafnapatam in the island of Ceylon, islands at the distance of some miles from the sea, but communicates with it by means of a river navigable with boats. The river falls into the sea near Point Pedro, where there are a fort and harbour. The fort of Jaffa was given up by the Dutch to the British troops, as soon as they appeared before it. It is small, but exceedingly neat and well built. The Pettah, or Black Town, without the walls, which is of a quadrangular figure, is large and more populous than that of Trincomalee. Since Columbo was taken possession of by the English, several Dutch families have quitted it, and taken up their residence in the vicinity of Jaffna; as this latter place is much cheaper and better supplied with all the necessaries of life, several of which are scarcely to be procured in the other parts of the island. The inhabitants of Jaffa consist of a collection of various races. The greatest number consists of Malabars of Moorish extraction, who are divided into several tribes, known by the names of Loubbahs, Belalas, Mopleys, Chittys, Choliers, and a few Brahmins;
they are distinguished by wearing a little round cap on their cloae flaven heads. There is also a race of Malabars found here somewhat differing in their appearance from those on the continent. These different tribes of foreign settlers greatly exceed in number the native Ceylonese in the district of Jaffna. The Malabars are employed in manufacturing cotton, cloths, &c. The Chittyas and Lubbahs trade in cloths, calicoes, handkerchiefs, &c. and go backwards and forwards to the continent to carry on this trade. The Lubbahs are Moors and Mahometans. The Belians are numerous; they are chiefly husbandmen and attend to tillage and rearing cattle. These are extremely litigious and quarrelsome; and, although professing Christians, they observe scarcely any of the ordinances of our religion. They are in some measure Pythagoreans; and say when a child is born lame, blind, or dumb, that it was formerly the soul of a person, who must have deferred this punishment by his actions in a former state. They are extremely superstitious, and attached to many of the rites of Paganism.

The Choliers and Chivias do the hard work; are porters, palanquin bearers, and water carriers; though some are defended from the higher order, and will only carry the great men. The Panias and Parias are the fishermen, as also the Mokkuns. The Nalouns are the blackest of all the tribes. They gather the toddy from the cocotrees, make arrack, tend the cattle, and are labourers and Coolies. The Parias are accounted the lowest and most despitable. All these in some measure partake of the Ceylonese customs and habits of life, mingled with their own. They inhabit various parts of the north-west coasts of Ceylon.

At Jaffna there is also a number of handcraftsmen, such as goldsmiths, jewellers, joiners, and makers of all different parts of household furniture. They are very expert in their respective operations; particularly that race known in this island by the name of Portuguse, who furnish all the rest in the beauty and dexterity of their workmanship.

JAFFNOO, a kingdom of Africa, bounded on the N. by Sahara or the great desert, on the E. by Ludamar, on the S. by Kaffon, and on the W. by Gedama. N. lat. 15° 10' to 15° 40' W. long. 7° 40' to 6°.

JAFFRAY, a polity-town of America, in Cheshire county, New Hampshire, on the S. side of the great Monadnock mountain, six miles N. of the Maffachutsetts line; incorporated in 1773, and containing 1,344 inhabitants. Here are found red and yellow ochre, alum, vitriol, and black lead in great quantities; and also buck-bean or nym-

JAFFRYGUNGE, a town of Bengal; 43 miles N.E. of Purneath.

JAG. See JAMNIA.

JAGFNA. See JAFFNY.

JAGFNPATAM, a district of Ceylon, comprehending an oblong peninsula in the northern extremity of the island, almost cut off from the rest by a branch of the sea, which penetrates across the island, except that a small strip of land remains, which is nearly inundated at high water. This district looks directly towards Negapatam on the Coromandel coast, and is considered as the most healthy in the island; a circumstance which is ascribed to its being surrounded almost on all sides by the sea, by which means the violent hot winds from the continent of India are cooled in their passage. The fields, clothed with verdant pasture, exhibit a convincing proof of the temperate nature of the climate. Fruits, vegetables, game, and poultry abound everywhere in this district; and it seems that the atmosphere differs in some respects from that which grows to other parts of the island; as it is only in the tract which lies between Point Pedro and Jaffna that sheep have been ever reared with success. The articles of commerce produced here are of no great value; the cinnamon and pepper being of an inferior kind to that which grows in the S.W. of the island. Negapatam was once a kingdom by itself, but was divided into several provinces. It is very populous, and has a great number of villages and churches, for all the various denominations of its inhabitants. The five lesser provinces contained in it are Beligame, Tenner-marche, Waddermarche, and Pathiapalle. The Dutch built a church in 1655 at Tchilpoli, near a shady and leafy grove. Several very good villages lie along this district, with churches and school-houses for educating the native children. The passage from Point Pedro to Negapatam on the opposite coast is usually made by boats in a few hours. The king of Jaffnapatam built a small fort here against the incursions of the Moors and Malabars. It was taken by the Portuguese in 1629, and lost by them in 1658. This was the last station retained by them in the island.

Dependent upon the district of Jaffna, and at a small distance in the sea to the north-west of Point Pedro, are several small islands, which the Dutch named from their own native cities, Delft, Haarlem, Leyden, and Amsterdam. These islands they employed in breeding horses and cattle, and as from their excellent pasturage they are better adapted to this purpose than any part of Ceylon. The English government continues the same system. The horses are bred under the superintendance of officers appointed for the purpose, and, when at proper age, are disposed on account of government. Percival’s Ceylon.

JAFRABAD, a town of Peria, in the province of Trak; 20 miles E.S.E. of Sava.

JAG, in Mining, signified formerly a crove or number of pack-horses, used for carrying ore, lead, &c.; and hence the carriers of ore for hire in Derbyshire are still called jaggars, although carts and wagons have long been substituted for pack-horses in this district. Jagg or join of ale, is also a term among the miners here for a quantity of ale sent for by a party of them at their work.

JAGA, in Geography, a town of Africa, in the country of Kaffon, on the south side of the Senegal. N. lat. 14°.

JAGA Calanda, a town of Africa, in the kingdom of Matamba; 70 miles N.W. Sta. Marin de Matamba.

JAGA Cacuns, a country of Africa, S. of Benguela.

JAGAMI, a town of Japan in the island of Nipon, 80 miles N.W. of Mexico.

JAGANABATTA, a town of Bengal, 42 miles S.W. of Burdwan. N. lat. 22° 35’. E. long. 87° 50’.

JAGANATH, in Hindu Mythology, a name of Vithnu and of Kriitha; more generally applied to the latter, who, under the designation of Jagananath, or lord of the universe, has a very celebrated temple dedicated to him in the territories of the raja of Berar. It is situated in the province of Cuttack, near the sea-shore in the bay of Bengal, and is annually visited by an immense concourse of pilgrims. It is said that all sects of Hindoos reverence the sanctity of this sacred temple, and revere thither in expiation, by ablations, prayers, alms, and austerities, of sin, or in the hope of spiritual or temporal advantage; it may, however, be concluded that the pilgrims are chiefly of the sect who exclusively worship Kriitha as the deity; which sect is called Gokulakul; Gokul being another of Kriitha’s names. The extreme care with which Hindoos avoid eating with an individual of an inferior tribe, or partaking of food so prepared, is a well known fact; but an exception from its generality is said to obtain at Jagananth, where the high and low, the Brahman and the
Pariah, associate and eat together. In the late war between the English and the Maharatta confederates, this temple, with the greater part of the province in which it is situated, fell into the hands of the former; but of course suffered no profanation: on the contrary, its sanctity was guarded with more than native vigilance; immunities were extended to pilgrims, and their approach to its holy precincts greatly facilitated. A similar policy at the sacred city of Benares has now for many years operated very favourably on the English character. While under Hindoo government, a heavy toll was imposed on the entrance of individuals, and this toll or tax was arbitrary, in reference to the suppozed wealth of the visitor. This, as may be supposed, gave rise to much vexation and injustice. Its abolition was a very popular measure, and has contributed, among other canes, to render Benares one of the most populous and wealthiest cities in the world. See Benares.

JAGARESTE, in Geography, a town of Thibet; 180 miles N. of Fyzabad. N. lat. 29° 58'. E. long. 81° 30'.

JAGARNAUT, a town of Hindoostan, in the province of Cuttack, famous for a grand pagoda, which lies a few miles E. of Chilka lake, and close on the sea-shore. (See Jagarnath.) It is an excellent sea-mark, on a coast that is perfectly flat and uniform. It has no claim to great antiquity; but major Rennell supposes, that it succeeded the temple of Sumnat in Guzerat, which was destroyed by Mahomed in the 11th century.

JAGAS, or JAGAS, savages of Africa, in the kingdom of Congo, (for which see) of whose cruel practices Cavazzi has given an account, that would be hardly credible, if it were not well authenticated. The women often expose their own children to wild beasts. Some of the Jaga princes take pleasure in eating young women, and their favourite dish is a fettus cut from the womb; and a prince's fate is to have been so fond of her gallants that she strangled them successively. The laws of the Jagas, called "quixillas," present a horrible code of vice and cruelty, being certainly the only rational code ever enacted for those brutal purposes. Their most delicious beverage is warm human blood. Indeed, the cruelty of the Jagas surpasses all description. Queen Zinga tore her own lion from her breast, and beheading him in a mortar, formed a horrible banquet, which continued to be made in the same manner of the bodies of babies. Being regarded as a sovereign charm, the Jaga chieffain, Caffangi, used to have a young woman killed every day for his table; and she was often feasted, who had passed the night in his bed. Zinga ordered that all her officers, before they proceeded on an expedition, should exercise the conjugal myteries in public, in the midst of a solemn assembly with the wife or concubine, who was the most favourite object of their love. The slaves among the Jagas die in a certain expectation of a similar but happier existence in another world; and it is esteemed an act of generosity to kill a beautiful female at the tomb of a friend: the Singhillas, or priests and magicians, are singularly despotic, and while they enforce the laws on others, effeem themselves free from their observance. Asafter a battle the bodies are claimed, each warrior is understood to wound in a particular part that he may inflict his prey. The women, by the account of the author above cited, are as ferocious as the men, and delight to cleave the skull and suck the warm brains of the slain. Five or six strong men will at once deftroy and share a captive, by cutting where their portions begin, and tearing him in pieces. But the above relation affords a sufficient specimen of their savage manners and conduct.

JAGERNDORF, in Geography, a principality of Sileia, originally part of Troppau, and yet established as a distinct principality in favour of duke Nicholas V; but ceded, at the peace of Berlin in 1742, by Maria Theresa, queen of Hungary and Bohemia, to Frederick II. of Prussia. Alfo, the capital of the above principality, situated on the Oppa, containing two churches and a convent; 12 miles N.W. of Troppau. N. lat. 50°. E. long. 17° 40'.

JAGERSBURG, a town of Brandenburg, in the New Mark; 15 miles E. of Arensfeld. — Alfo, a town of Hefs- Darmtadt; 13 miles S.S.W. of Darmstadt.

JAGHUS, a town of Germany, in the Tyrolese; 14 miles N.W. of Schiwaz.

JAGHIRE, a term in India, which denotes a grant of land from a sovereign to a subject, revocable at pleasure; but generally, or at most always for a life rent. Hence are derived "jaghirdars," or holders of jaghiries; their titles to their possession being nominally during their life-time only, though some of them in the Maharatta State have long since become hereditary. This term "Jaghire" is applied to the East India company's lands in the Carnatic, extending from Madras to the Pullicate lake, northwest; and to Alem-pur, southwards; and wellward, beyond Conjarernam: that is, about 108 British miles along shore, and 47 inland, in the widest part. This Jaghire is underfounded to be held in perpetuity. It contains about 24,400 square miles; and its revenue is reckoned at about 150,000l. per annum.

JAGIPOUR, a town of Hindoostan, in Bahar, on the left bank of the Ganges; 48 miles E.S.E. of Hajjypour.

JAGNEVO, a town of European Turkey, in Servia; 8 miles S. of Prifina.

JAGNIDE, Ital. See Hyagnis.

JAGO, in Geography, a town of Africa, in Guinea, on the river Formoza; 70 miles from the sea.

JACO, St. the capital of the kingdom of Chili. See Santiago.

JACO, Sr. a town of the island of Cuba, which was formerly its capital, but of late much reduced from its former splendour, is situated at the distance of 269 leagues from Havana, in a hilly county, subject to frequent earthquakes. It lies near the south coast, on a bay, about six miles from the sea; the haven is fpacious and secure, the entrance being by a channel two leagues in length, defended by a cantele at the extremity. The towns are regarded as the most handsom in the island. It is the fee of a bishop, suffragan of St. Domingo. N. lat. 20° 15'. W. long. 75° 32'. See Cuba.— Alfo, a town of Mexico, in the province of Guaxaca; 45 miles E.S.E. of Guaxaca; which fee. — Alfo, a river of Mexico, which runs into the Pacific ocean, N. lat. 22° 30'. W. long. 156'. — Alfo, a town of New Mexico, in the province of New Leon.—Alfo, a town of California; 120 miles W. of Loretto.—Alfo, a town of Paraguay; 154 miles S. of Assumption.—Alfo, a river of Peru, which runs into the Pacific ocean, N. lat. 15° 20'.

JACO, St. or Santiagos, the chief of the Cape Verd islands; it is one of the most fertile and best cultivated, about 40 British miles in length, by 20 in breadth. Although it has many mountains, it has been reckoned the most unhealthy of these islands. The people are generally black, or of a mixed colour; a few of the better rank excepted. The principal production of this island is cotton; and the chief fruits are grapes, plantains, citrons, lemons, oranges, mulk and water melons, limes, guavas, pomegranates, quinces, collard-apples, papas, and other tropical fruits. Its animals are cows, hores, affe, mules, deer, hogs, goats, and black-faced monkes with long tails. Of the feathered birds there are cocks, hens, ducks, Guinea hens, parroths, pigeons, turtle-doves, crab-catchers, curlews, and many of them valuable for their plumage. The population of this
island is estimated at about 12,000 persons. When it was visited by Sir George Staunton in November, 1792, in his voyage to China, the island was in a state of absolute famine. Little or no rain had fallen there for three years before, the rivers were almost entirely dry; the surface of the earth was in general delituitude of any herbage; the greatest part of the cattle had already perished, not less through drought than want of food. Of the inhabitants many had emigrated, and many were famished to death. The plains and fields, formerly productive of corn, figs-canes, or plantains, nourished by regular falls of rain, now bore little semblance of vegetation. Of the island of St. Jago, the south-west side only had any appearance of volcanic formation. About twomiles from Praya bay is a very high hill, altogether composed of clay and sand, on which appeared not the least marks of the action of fire. About six miles, near the road, from the town of Praya to that of St. Jago, is another hill, almost entirely composed of rich iron stone, of a deep blue or purple colour, formed of clay, calx of iron, and siliceous earth. In the rocks opposite the governor's house, near Praya, are several narrow perpendicular veins of white spar. The beach is covered with a fine siliceous sand. The Portuguese maintain no force at St. Jago, capable of infuring a proper respect to their flag there; and so far are they from drawing any revenue from the place, that supplies are sent to it from Portugal. A trade for slaves from Africa is established at St. Jago; and that trade is a monopoly, or to the crown. The governor derives his chief profit from the sales of cattle to the ships which call there; and of the amount of these sales he claims a moiety. Such is the state of the inhabitants, that they altogether depend for a supply of whatever their own island cannot afford, upon vessels casually floating there. They set little value upon money, which might long lie uselefs in their hands; preferring to barter whatever they have to sell, for a return, principally of corn or clothing, rather than any quantity of specie that would be offered to them. The water obtained here is neither good nor easy to be had. The chief towns are St. Jago and Praya. N. lat. 15° 41'. W. long. 23° 40'.

Jago, St., Ribera, or Riviira, a town of the above-mentioned island, and formerly its capital, is situated in the bottom of a vale, between an elevated plain, on the boundary of which is a fort in ruins, which was originally defigned to defend the fleet, which, on the south, towards the town, and a high hill opposite to it. This vale seemed to have been scooped out by the force of a violent torrent, rolling along with it great rocks which stood in its paffage, and emptying itself with them into the sea. There a small, irregular, and unsafe harbour was formed by these rocks, while the current itself is diminished into a strem, so small and sluggish, that it cannot clear its mouth from the fands which the tide throws in, and by which it is almost choked up. On each side of this little strem are remains of dwellings of considerable solidity and fire; and the fragments of glass hulles, full hanging from the ceilings of the principal apartments, denote the elegance or riches that were once displayed in this now defecfed place. It had formerly 300 houes built of rough stone, a church, and a convent. But Sir George Staunton, who visited it in his "Embassy to China" says, that not above half a dozen families remained in it; the rest had abandoned it, or perished. He adds (Vol. i. p. 135.) here was still, however, an attempt at a flight manufactory of striped cotton flaps, the same as are made in other parts of the island, for the use of the Africans on the Main, who pay for them in flaves, elephants' teeth, and Arabic gum. The governor now refides at Porto Praya, which is frequented by the ships that, for commercial or other purpofes, touch at this island. See Porto Praya.

Jago de los Cavallerius, St., a town of the island of Hispaniola; 90 miles N. of St. Domingo. N. lat. 19° 56'. W. long. 70° 52'.

Jago de Compostella, St. See Compostella.

Jago del Effero, St., a town of South America, capital of the country of Tucumán, and face of a bishop; situated on the banks of the Dulce, which, here large and navigable for vessels of burden, and which affords great plenty and variety of fish. The town contains about 200 houses, or 500 families, and is defitute of walls, ditch, or other fence. The inhabitants are mostly melizos and mulattoes, of a dark yellow complexion, indolent and fickly from the heat of the climate, and more addicted to pleasure than labour. Surroundcd with forests, and situated on a plain, the town suffers from a flagration of air. It has hardly 300 men fit for bearing arms. The women, who are generally handsomc, are troubled with fwellings or wets in the throat. The adjacent country produces plenty of wheat, rice, barley, and all farts of fruits, particularly figs and raffins. The forests, which yield abundance of game, are infected with tygers and other beasts of prey; 650 miles N.W. of Buenos Ayres. N. lat. 27° 56'. W. long. 65° 12'.

Jago de Gataeya, St., a town of Peru, in the diocceu of Lima; and chief town of the jurisdiction of Chicas, under the government of Buenos Ayres; 80 miles S. of Potosí.

Jago de Leon, St., See Caraccas.

Jago de los Montanas, St., a town of South America, in Quito; 10 miles N.W. of St. Francisco de Borja.

Jago Samachez, St., a town of South America, in the province of Buenos Ayres, on the Paraná; 25 miles S. of Corrientes.

Jago de los Valles, St., a town of Mexico, in the province of Guatleca, on the river Panuco; 60 miles S. of Panuco. N. lat. 22° 40'. W. long. 100° 36'.

Jago de la Vega, St., See Spanish Town.

Jago de Veraguas, St., a town of Mexico, and capital of Veraguas, situated in a fertile country, abounding with maize, plantains, &c. and plenty of cattle. It contains an elegant hospital, and is the seat of a governor, whose authority extends over 14 towns and villages; 110 miles S.W. of Porto-Bello. Nat. lat. 8° 46'. W. long. 81° 46'.

Jago, St. Military Order of, See St. James of the Sword.

JAGODINA, in Geography, a town of European Turkey, in Servia, on a small river, which runs into the Monava; 60 miles S. S.E. of Belgrade. N. lat. 45° 15'. E. long. 20° 56'.

JAGOLEAH, town of Bengal; 21 miles N.N.E. of Calcutta.

JAGOTPOUR, a town of Hindoostan, in Oude; 16 miles N. of Manickpur.

JAGOVAT, a town of Persian Armenia; 12 miles N. of Erivan.

JAGRA, or Jaggery, a name given to a peculiar species of sugar, prepared from the coco-nut. This is prepared in Ceylon from a liquor called "toddy," procured, by infining, from the top of the tree where the leaves float up; a flec is made in this part of the tree with a knife over night, and a 'chaty," or earthen pot, fupended from the branches fo as to receive the juice, which immediately begins to dilute, and continues to do fo till next morning, when the pot is removed. This liquor, when drank before the heat of the riving sun has caufed it to ferment, is very wholesome and cooling, and operates as a gentle purgative. But upon being fermented it becomes intoxicating; and in this state is well known to the European soldiers, who use it in large quantities when they cannot procure the arrack 'distilled from it. Arrack in Ceylon is wholly made from toddy, and whole woods of
the cocoa-tree are employed for the purpose of procuring it. A barm or yeaf arises from this proces, equal to that which is procured from our malt liquor made in the preparation of whisky. The toddy is likewise made into vinegar, and yields a species of coarse black sugar known by the above name.

**JAGRAH**, a town of Hindoostan, in the circuit of Nagore; 15 miles N. of Nagore.

**JAGRENATPOUR**, a town of Bengal; 10 miles N.W. of Purneh, near Algo, a town of Bengal; 20 miles W. of Isfahanabad.—Algo, a town of Hindooollah, in Bahar; 65 miles S.S.E. of Hajypour.

**JAGUA**, a town of the island of Cuba; 85 miles W.S.W. of Havana.

**JAGUACAH-GUACU**, in Ornithology, the name of a Brazilian bird of the king-fisher kind, called by the Portuguese papa pecoe. See Alcedo Alycan.

**JAGUARA**, in Zoology. See Felis Onca.

**JAGUARACA**, in Ichthyology, the name of a Brazilian fish, in many things resembling the scorpion of the Mediterranean. It is of the size of the fresh-water perch, and its mouth is very large, but without teeth. It is caught among the rocks, and is a very well tailed fish. Margrave.

**JAGUARETE**, in Zoology. See Felis Dicobar.

**JAGUILMA**, in Ornithology, a species of Ptilatus; which fee.

**JAIL.** See GAOL.

**JAIL-FEVER, in Medicine.** See Fever and Typhus.

**JAHANABAD**, in Geography, a town of Bengal; 20 miles S. of Burdwan. N. lat. 22° 55'. E. long. 87° 55'.

**JAHANAGUR**, a town of Bengal; 10 miles W. of Kifkenagur.

**JAHEDIANS**, a sect of Mahometans, the followers of Ameer Ebn Bahr, surnamed Ali Jahed, a great doctor of the Mottazzalites, and much admired for the elegance of his compositions, who differed from his brethren in imagining that the damned would not be eternally tormented in hell, but would be changed into the nature of fire, and that the fire would of itself attract them, without any necessity of their going into it. He also taught that if man believed God to be his Lord, and Mohammed the apostle of God, he became one of the faithful, and was obliged to nothing farther. Of the Koran, he used to say it was a body, which might sometimes be turned into a man, and sometimes into a beast; seeming to agree with the notion of those who assert the Koran to have two faces, one of a man, the other of a beast; thus probably intimating the double interpretation which it will admit of, according to the letter, or the spirit.

**Jahi, in Geography, a town of Asiatic Turkey, in Nattolin; 16 miles N.N.E. of Angara.**

**JAHNU, in Hindoo Mythology,** is called the father of the Ganges, from an extravagant story of an auditive face, named Jahnu, having been disturbed at his devotions by the intrusion of the river. In anger he swallowed the whole limb, but, relenting, poured it forth again from an incision in his thigh, or, according to others, from his ear. Ridiculous as this wild story may seem, it has probably some historical allusion, for it is generally admitted that both the history and science of the Hindoos are veiled in mythological fables, taken literally by the people, the Brahmins only posseing a knowledge of their real import. This fable of Jahnu is frequently alluded to in Hindoo writings, and forms considerable scope for poetical exubrance. Moor's Hindoo Pantheon.

**JAHNUVI,** a name of the river Ganges, or Ganga, as it would be more properly written. The river obtained this appellation, which means the offspring of Jahnu, from the circumstance above mentioned.

**JAHUPICE,** in Geography, a town of Poland, in the palatinate of Braclaw; 48 miles S.E. of Braclaw.

**JAICZA,** a town, with a castle, of European Turkey, in Bofnia, near the river Pliva; 26 miles S. of Banjuluka.

**JAICZI,** a town of Great Bucharia, on the Jihan; 36 miles S. of Bokhara.

**JAIMINI,** in Philosophy, the founder of a school in India, professing tenets similar in many parts to those taught by Socrates. Jaimini inculcated the unity of the deity, rejecting the Iteries, fo generally received by many sects of Hindoos, of the incarnations of deities. He maintains that the great powers and attributes of the deity Brahma, Vishnu, and Siva (perfoninations, of creation, pervation, and destrucion), were men, who, through righteoufness, attained a high degree of perfection, and were endowed by the deity with qualities approaching to his own attributes. His followers call this doctrine Purwa Mimana, distinguishing it from another branch of Jaimini's philosophy called Vedanta, between which difTerentiation is not easy. (See Vedanta.) Mimana is the general name for the philosophy of Jaimini, which is upheld by many learned Hindoos. It teaches the eternity of the elements, and of the univerfe; that bodies are only a compound of atoms, and not produced from one substance; that man is a free agent; that rewards and punifhments hereafter differ in degrees, according to virtue or anim. The tranmigration of the foul is also a tenet in the Mimana philosophy. See MIMANIA.

**JAINA,** the founder of a sect, whose tenets have spread very extensively over India. By some authors the sect of Jaina, or Jina, as it is sometimes written, is supposed to be a subdivision of that of Budha, or Booodha (see BOODHA), while others contend for its originality and antiquity over most other of the sects into which the Hindoos are theologically subdivided. Between the Jainas and the Brahmins, a degree of malignity appears to have exalted formerly, greater than is now any way difTerenct. Abul Fazul, in the Ayin Acairee, a work written about the year 1600, A.D. has the following paillage: "From the most ancient times down to the present, the learning and wisdom of Hindoos have been confined to the Brahmins and the followers of Jaina; but ignorant of each other's merits they have a mutual aversion. Krihna, whom the Brahmins ('of his own sect, it should have added, for it is not true of them universally) "worship as God, the Jaina consider as an inferior slave; and the Brahmins carry their avenion so far as to say, that it is better to encounter a mad elephant than to meet a man of this perfeucion." This mutual malignity led to the horrible extences of religious perfeucion, inflamed by the jealousy of rivalry, and the bafer feelings of hatred and revenge. In these conflicts the Jainas are related to have suffered most disfarrishing from the superior prowess and adreces of the Brahmins and their adherents, who destroyed the temples, books, &c. of their ill-fated opponents, expelling the remains of the sect to the confines of India. Such, however, is the tendency of herey, cemented, as it were, by perfeucion, that the followers of Jaina are now found to have re-established themselves in the more central parts of the peninsula of India, where the mildnefs of their manners and tenets appears to gain them profelytes and recepedt. It is, however, on the western coasts of the hither peninsula that this interesting people have of late been most noticed by travellers. In the provinces of Kanara and Myore, particularly in the former, Jainas in considerable numbers now freely
freely practised the ceremonies of their religion, and unmeasured indulges in their whimsical, and extravagantly profane propensities. Their leading tenet is "the sin of depriving any animal of life," and in obedience to this humane precept, they not only abstain wholly from animal food, but some among the fiercer individuals will not drink water until it hath been boiled; it being deemed les criminal to kill the animal than to destroy them in their stomachs. Others carry a broom to sweep the ground on which they tread or sit, left them inadvertently crust an infect. The Jains are the sect who endow the hospitals for animals and reptiles, that have attracted the attention of several travellers. These hospitals are called Pinji-pals, meaning an enclosure of protection, and afford it to almost every description of animal, monkeys more especially; weevils and other diminutive reptiles are morred in these receptacles of ill-directed charity. The Jains are deities in doctrine; they worship one supreme being under the denomination of Ar-hang Paramatma, which in the Sanscrit language means the supreme soul; they reject the polytheism and incarnations of the orthodox Hindus, but they honour, almost to deification, twenty-four holy persons whom they call Aryhuntas, of whom images are made and placed in their temples. Of these Aryhuntas, or Tirthankaras, as they are otherwise denominated, Rishaba Deva is the first in point of time and veneration. To him are ascribed the existing books of their laws, religion, and morals: of these sacred persons and books lists are given, with many curious particulars respecting the Jains of Guzerat, in Moor's Hindoo Infanticide. All the Aryhuntas have the common denomination of Deva, meaning divine, or God like, appended to their names. Among the Jains the division into tribes or castes is not observable as among other Hindoos; Yati and Sravaka being their only distinctions. The former are a sort of priest, or rather spiritual preceptor, who read and expound to the Sravakas or laity, the Sstras or scriptures of the Jaina faith. The Yatis are devoted to religion from their infancy, and are admitted to this distinction after a due course of study and piety. They profess celibacy and abstemious, reciting a verie fast to impair their duties: "that person who keeps his five senses under subjection is a Yati?" this denotes the Yati with the Jains to be equivalent to a Saniably among the orthodox Hindoos. (See Sanyass.) The Yati lives by charity; he may not dres his food himself, nor eat while the sun is below the horizon; roots of all sorts, honey and butter unclarified, are prohibited; all kinds of grain, vegetables, and fruit, produced above ground, with milk and cheese, or butter clarified, are lawful food. The Yati is supposed to have renounced the world and all sensuous gratifications; he affects a contemplative indifference, performing no offices of mourning or rejoicing. The Yati performs no religious rites; he is merely an ascetic and spiritual guide. The Sravakas refer to some feats of orthodox Brahmans for the performance of marriage, funeral, and other ceremonies. See Sravaka and Yati.

The Jains, like the other Buddhists, or adherents of Budha, are addicted to gigantic sculpture. In the province of Kanara is a colossal figure of Jain-deva, of a magnitude unequalled perhaps by any now in existence. Of this statue, major Moor has given a description and a plate in his Hindoo Pantheon. It is upwards of seventy feet in height, and being situated on an eminence, called Indra-giri, or the hill of Indra, is seen in all directions from a distance of twelve or fifteen miles. Major Moor's print is taken from a sketch in the collection of lord Wellington, who has visited the statue, and judged that the hill on which it now seems to stand, was once considerably higher, and that it has been cut away, leaving only the figure; a mode of sculpture similar, although under different circumstances, to the subterranean excavations of Elephants, Kenveeh, and other temples. It is, major Moor observes, difficult to conceive how in any other mode such a mass of stone could have been so situated, its magnitude precluding the supposition of conveyance and erection. Other colossal figures of the Jaines of Kanara are described and represented in the Hindoo Pantheon; also a very beautiful obelisk, 52 feet in height, the shaft of one stone, in front of one of their temples, indicating a degree of taste and refinement in architectural science, that could scarcely be expected under the political and theological discouragements to which the persecuted Jains are believed to have been subjected. One singularity is strikingly observable in all the images, colossal or diminutive, of the Buddhists and Jains; they have woolly frizzled heads, and many of them thick lips; such as might be expected in Africa, but altogether dissimilar to the features and lank hair of the Hindoos. See on the subject of this article Asiatic Researches, vol. ix. Moor's Hindoo Pantheon. Moor's Hindoo Infanticide.

JAINAD, in Geography, a town of Hindooslan, in the circar of Mahur; 33 miles N. of Neemul.

JAIRE, a town of France, in the department of the Leman; 15 miles S.E. of Geneva.

JAK in Jakee, a town of Africa, on the Ivory coast.

JAK, a kingdom of Africa, 500 miles from the sea, with a capital of the same name, on the S. side of the Senegal.—Alo, a town and district of Africa, on the Ivory coast.

JAKAI, a town of Circassia; 45 miles W. of Ekikese.

JAKIN, a town of Africa, in the kingdom of Ardra, on the Slave coast, where the English and Dutch had factories, till they were driven away by the king of Dahomy.—Alo, a river which separates the country of Ardra from Benin, and runs into the sea at Grand Popo.

JAKIRA, a town of Africa, on the Slave coast; 10 miles S. of Afiom.

JAKOBSHAVN, a Danish settlement in Greenland.

JAKOWIZINA, a town of Kufian Poland, in the paltinate of Braclaw; 36 miles W.N.W. of Braclaw.

JAL, a town of Peria, in the province of Mecran; 210 miles N. of Kidge.

JAL, a small island in the Atlantic, near the coast of Africa. N. lat. 11° 45'.

JALAC, a small town of Nubia, at the conflux of the Taza and Nile; 240 miles S. of Senmara. N. lat. 17° 50'. E. long. 34° 10'.

JALALABAD, a town of Candahar, in the country of Cabul, on the river Kameh; 60 miles E.S.E. of Cabul. N. lat. 34° 6'. E. long. 69° 45'.—Alo, a town of Hindoostan, in the circar of Schaurinpour; 26 miles from Schaurinpour.

JALALGUNGE, a town of Bengal, and principal place of the province of Bajoooh; 25 miles N.N.E. of Goragot. N. lat. 25. 28. E. long. 82° 30'.

JALALPORUM, a town of Hindoostan, in the circar of Schaurinpur; 20 miles N.N.W. of Morat.

JALAM, a town of Arabia; 35 miles S. of Mecca.

JALANGHI-LIMAN, a town of Asiatic Turkey, in Natolia; 12 miles S. of Smyrna.

JALAP, in the Materia Medica, so called from the name of the country, viz. Chalapa, or Xalapa, a province in New Spain, between La Vera Cruz and Mexico, whence it is brought,
brought, the root of a species of convolulus, or the convolulus with variable leaves, foot-flakes with single flowers, and a tuberous root. Botanists have differed much with respect to the official jalap plant; Linnæus, following Clusius, Plinius, Tournefort, and others, first referred it to the Mirabilis; but in the second edition of his Materia Medica, he adopts the opinions of Ray and Miller, in considering it a convolulus; and, indeed, after the account given of this plant by Dr. Houlton, no reasonable doubt can remain on this subject.

The mechaean and this are reckoned of a species; and therefore as this is sometimes called mechaeanā nigra, that goes as often by the name of jalapium album.

As jalap does not appear to have been known to the ancients, it has its place in medicine only since those parts of America, which produce it, have been traded to by the Europeans. It is said to have been first brought to Europe about the year 1610.

The jalap roots are brought over in thin transverse slices, and also whole, of an oval shape, solid, hard, and heavy; of a blackish colour on the outside or cortical part, and internally of a dark grayish, with several black circular lines; the hardest, darkest colored, and those which have the most of these redous veins, are the best. This root has scarcely any smell or taste; but to the tongue, and the throat it manifests a slight degree of pungency.

The medicinal activity of jalap retides principally, if not wholly, in the resin, which, though given in small doses, occasions violent torments. The gummy part bears an inconsiderable proportion to the resinous, and is found to have little or no cathartic power, but as a diuretic it is extremely active.

In doses of a ferule, or half a dram, it is an effectual and safe purgative, very rarely occasioning any fever or gripes or nausea. Jalap is an excellent purgative in dropsical and other cases, in which ferous humours are to be evacuated. Jalap, in large doses, or when joined with calomel, is recommended as an anthelmintic and a hydragogue; and from its general efficacy in dropsics was called "Panacea Hydropetricum." Hadman thought it particularly improper and unsafe to administer this medicine to children; but Dr. Cullen obersves, that if jalap be well triturated before exhibition with a hard powder, and the crysals of tartar are the tincture for the purpose, it will operate in lesser doses than when taken by itself, and at the same time very moderately, and without griping. Except he says, when given in very large doses, I have not found it to be heating to the sytem; and if it be triturated with a hard fugar, it becomes, in moderate doses, a safe medicine for children, which in this form they will readily receive, as the jalap itself has very little taste. But it should not be administered, says Geoffroy, in acute fevers, nor to persons of dry and hot constitutions; for in such cases, it is liable to the same mischief as other acrid purgatives, and will sometimes bring on heat and inflammations in the viscers.

The preparations of jalap in use with us are a tincture, an extract, and a reinf. The tincture is made by macerating eight ounces of jalap root powdered in two pints of proof spirit for 14 days, and draining. The extract is prepared by first drawing a tincture from the powdered root with rectified spirit, in the proportion of a pound of the root and four pints of the spirit, macerating the root in the spirit for four days, and pouring off the tincture; then boiling the residuum in ten pints of water, until it be reduced to two pints; then strain the tincture and decoction separately, and let the former be distilled, and the latter evaporated until each begins to grow thick. Lastly, mix the extract with the reinf, and reduce it to a proper consistence. Let the extract be kept in a jar safe fit for forming pills, and in a hard state so that it may be reduced to powder. This extract may be taken by itself in doses of twelve grains, or more. Jalap root, digested in as much rectified spirit as will cover it to the height of about four fingers, gives out the greatest part of the resinous matter in which its activity resides, and tinges the mucous membrane of a yellowish brown colour. On infusing the filtered tincture to an amount one-half, and adding to the remainder a proper quantity of water, the liquor becomes milky, and on standing deposits the pure reinf. This preparation, by itself, irritates and gripes much, without proving considerably purgative; but thoroughly triturated with telluraceous or other powders, or with soap, or ground with almonds, or powdered gum arabic, and made into an emulsion with water, or dissolved in rectified spirit, and mixed with a proper quantity of syrup, that the solution may bear being diluted with watery liquors without precipitation, it purges, in doses of eight or ten grains, as effectually, and, for the most part, as mildly as the jalap in substanse. Lewis's "Mab. Med."

The Edinburgh college directs the exhibition of jalap in powder, with twice its weight of crysals of tartar. The dose of the simple powder is commonly one ferule to two of the compound powder it may be double this quantity, which is nearly equal to 10 or 15 grains of the extract, or about two draams of the tincture. Woody. "Mab. Med."

Bot.

After all the preparations of the chemists have invented for this root, the best way of giving it is in substanse. Mr. Bolduc, in his analysis of it, found, that when he separated its saline and its resinous parts, by making extracts of it, first with spirits of wine, and then with water, that the saline or watery extract was much larger in quantity than the other, but that it purged weakly; and that the resinous extract, though it operated in a small dose, was yet a very rough medicine; to that the best way of using them was together, and that nature gave us the medicine ready prepared. Mem. Acad. Par. 1701.

However, others have observed, that the extracts of jalap appear preferable to the root in substanse, not only on account of the dose being rendered smaller by the rejection of the woody parts, but likewise as being more uniform and certain in strength. Lewis.

Many fraudulent chemists, when jalap is dear, have a trick of putting scimmony, which is of itself almost all reinf, among it, and sometimes gamboge; by which means they can afford to sell it cheaper than the price it can be honestly made for. But their most curious cheat is in mixing it with the common black reinf; two parts of the latter to one of the former. But this may be known by putting it into rectified spirit, which will again dissolve the reinf of jalap, but not touch the other. The virtues are the same with those of the root, but it works rougher, because all substanse flock to the coasts of the intestines, so to occasion much pain and uneasiness; for which reason this is corrected with fugar, cream of tartar, or the like; by which means it is brought into the same state as nature presents it in the root. For some purposes, indeed, where the form is required to be small, as often in administration to children, this is most convenient. Its dose is from three grains to one ferule.

Jalap posseses a fermenting power in a considerable degree, and is said to be used with this intention by brewers and distillers.

JALAPA, in Botany. See CONVOLVULUS and MIRA-

BILIS.
JALASJARVI, in Geography, a town of Sweden, in the government of Vasa; 40 miles E.N.E. of Chrifhtinefalt.

JALEA, a town of African Turkey, in Natalia; 12 miles S.W. of Ahmaduti.

JALEH, a kind of raft of a particular construction, used in navigating some of the rivers in India, particularly the Cabul or Kameh, on which some of the emperors have made voyages down this river from the neighbourhood of Jalalabad, 60 or 70 miles below Cabul, to Paghawur. As no embarkations of the hollow kind are in use, it seems to prove that the navigation is interrupted by rapids; for there can be no doubt but that the body of water in the Kameh is sufficient to carry boats.

JALEMGORI, in Geography, a town of Hindoostan, in the círcar of Soolapour; 18 miles E. of Soolapour.

JALEMUS, Jalemo, or Jalemi, in Antiquity, a kind of mournful song used upon occasion of death, or any other affecting accident; such as the Linos was among the Greeks, and the Maneros among the Egyptians. (See Song.) Hence the Greek proverbers had their original, Ἰαλέμων, οὐ τὸν Ἰαλέμων, i.e. more sad or colder than a jalemus; τὸν Ἰαλέμων γέλατον, worthy to be ranked among jalemoses. Mem. Acad. Inscript. tom. xiii. p. 554.

JALI, in Geography, an island in the Grecian Archipelago, about five miles in circuit; four miles S.E. of Stanchio.—Alfo, a town in the island of Borneo; 70 miles N. of Negara.

JALIGNY, a town of France, in the department of the Allier, and district of La Pâfle; 15 miles S.E. of Moulins. The place contains 482, and the canton 8114 inhabitants, on a territory of 280 kilometres, in 12 communes.

JALLA, a town of Hindoostan, in Bahar; 18 miles N.N.W. of Durbungah.

JALLACOTTA, a town of Africa, in the country of Tenda; 10 miles W. of Tenda. N. lat. 13°. W. long. 12° 9'.

JALLAIS, a town of France, in the department of the Mayne and Loire; 7 miles N. of Chollet.

JALALL, a river of Spain, which runs into the Atlantic, N. lat. 42° 59'. W. long. 9° 12'.

JALLINDAR, a círcar of Hindoostan, in the country of Lahore, of considerable extent, between the rivers Satledge and Beyah.—Alfo, the capital of this district; 50 miles E. of Lahore. N. lat. 31° 16'. E. long. 75° 25'.

JALLOFFS, or Yalloffs, a people inhabiting an extensive interior territory of Africa, between the rivers Gambia to the south, and the Senegal to the north and east; or between about 14° and 16° N. lat. and 15° and 17° W. long. Of these people little certain is known; but they are represented as of an exceeding black, and more beautiful complexion and more regular features than the inhabitants of the neighbouring countries.

JALLONKADO, an extensive country of Africa, lying between Guinea on the S.W. and Manding on the N.E. and containing either the springs or firth courses of the rivers Niger and Senegul, and also of several other streams which form the Boki, Furkoomah, Wondo, Koko, etc. It is between the parallels of 11° and 12 N. lat. and 6° and 6° 6' E. long.

JALLYNE, a town of Bengal; 20 miles W. of Nagore.

JALOAN, a town of Hindoostan, in the círcar of Go- bud; 10 miles N.N.E. of Koch.

JALOR, a town of the Carnatic; seven miles N. of Ootatore.

JALONITZA, a town of European Turkey, in Wala- chia, on a river of the same name; 95 miles S.W. of Ismail.

JALOUR, a large town of Hindoostan, situated on a mountain difficult of access, in the country of Agimere, and círcar of Siroya; 53 miles W.N.W. of Oudipour. N. lat. 25° 15'. E. long. 73° 40'.

JALOWKA, a town of Lithuania, in the palatinate of Troki; 24 miles S. of Grodno.

JALPIG, a lake of European Turkey, in Beffarabia, 50 miles long, and from three to five broad, communicating with the Danube, and receiving water from a river called by the same name at Tabak; 15 miles W. of Ismail.

JALYSUS, or Jallus, in Ancient Geography, a town situated on the N.W. coast of the island of Rhodes; founded, according to Herodotus, by the Danaides, and fortified on occasion of the Peloponnesian war.

JAM, a town of Greater Bucharla; 10 miles S. of Samarcand.

JAM, or Jamb, in the language of our lead-miners in Mendip, a thick bed of stone, which hinders their work when they are purifying the veins of ore.

JAMA, in Geography, a river of Peru, which runs into the Pacific ocean, S. lat. 9° 10'.

JAMACAI, in Ornithology. See ORIOLUS JAMAICAI.

JAMADA, in Geography, a town of Japan, in the island of Xicoco; 20 miles W. of Ovuth.

JAMADAGNI, in Hindo Mythology, is the father of Parafo Rama, by his wife Runeca. (See RANELA.) He was a pious Brahman, who, in his retirement, was enthralled by Indra with the charge of Surabbi, the wonderful cow, which granted every desire, hence named Alfo Kamdem. (See SURABBI.) On a particular occasion he entreated the raja Diru in so magnificent a style as to excite his astonishment, until he learned the secret of the ineffinable animal possessed by his host. Impelled by curiosity, or rather heart-hardened by the gods, who willed the raja's punishment should appear to be the immediate result of that base passion, the raja demanded the cow from the holy Brahman; and on refusal referred to fratagem and force, which ended in the death of Jamadagni, but not in success with respect to the cow, which disappeared. Jamadagni is flated to be defended from Bhiguni the son of Brahman. and is one of the seven Rishis, the immediate offspring of the creative power. Moor's Hindoo Pantheon. See RISHIS and MENU.

JAMADUKURI, in Geography, a town of Japan, in the island of Niphon; 50 miles S.W. of Nambu.

JAMAGA, a town of Japan, in the island of Ximo; 22 miles E. of Ovuth.

JAMICA, an island of the West Indies, discovered by Christopher Columbus in his second expedition to the New World, May 3, A.D. 1494, retaining its original name. The early Spanish historians for Jamaica wrote Xaymaca, which in the language of the nation is said to have signified "a country abounding in springs." Columbus having at first named the island "St. Jago," Oldmixon, and some other writers, erroneously suppose that Jamaica was the augmentative of James. It was not, however, till about nine years after its first discovery that he had an opportunity of acquainting himself further with the island; in consequence of a storm which compelled him, on the 24th of June 1503, on his return to Hispaniola from Veragua, to seek refuge in a small harbour on the N. side, called to this day "Don Christopher's Cove." About seventeen years elapsed after the Spaniards had first fixid themselves in His- pinola before they seem to have entertained any serious design of founding a colony to take possession of Jamaica; and the neglect of it was probably owing to its producing neither
neither gold nor silver. At length, however, Diego, the son of the much injured Columbus, and the heir of his fortunes, instituted a memorable process against his sovereign before the council of the Indies at Seville, and obtained from this court a decision in favour of his pretensions. The council pronounced him hereditary viceroy and high admiral of all the countries and islands discovered by his father. Diego, thus functioned in his proceedings by the high authority of this court, embarked, with a specious pretence, for his government of Hispaniola, to which the king had reluctantly appointed him; determined at the same time to enforce his pretensions. In July 1508 he arrived at Hispaniola, where he found two persons actually invested by the king with two separate governments, that comprehended the whole continent discovered by Christopher Columbus, including also the island of Jamaica. Diego, thus deprived of his rights, strenuously contested for the exclusive privilege of nominating, in particular to the governments of Venezuela and Jamaica, the prior discovery of both the countries being a circumstance of universal notoriety. For securing his claim to Jamaica he sought thither, in November 1509, Juan de Esquivel with about 70 men. Under this gallant and equally humane commander, the natives were induced to submit without effusion of blood, and prosecuted their labours in planting cotton, raising other commodities which yielded great profit. After a few years he died, and was succeeded by governors of a very different character, who contributed to destroy the inhabitants and to defoil the island. Sixty thousand of the wretched natives, on the most moderate estimate, were exterminated by the Spaniards; so that not a single defendent of either sex appeared to be alive when the English took the island in 1655, nor perhaps for a century before that period. It is said, indeed, that a small remnant of the ancient Indians exists on the S. side of the island of Cuba, in a little town called St. Jago de Cuba, or Iwance, and that these have adopted the manners and language of the Spaniards.

Diego Columbus, who died in his native country in 1525 or 1526, left issue three sons and two daughters; his eldest son Don Lewis succeeded to his father's honours and extensive claims; and in 1535, upon a compromise of a content with the emperor, obtained a grant of the province of Veragua and the island of Jamaica. As he and his brothers died without issue, his sister Isabella, who was married to the Count de Gelves, a Portuguese nobleman of the house of Braganza, became sole heiress of the Columbus family, and by her marriage conveyed all her rights to the house of Braganza, in whole possession they retained till the year 1640, when they reasserted by forfeiture to the crown of Spain, in consequence of the revolution, which placed John, duke of Braganza, on the throne of Portugal. From circumstances elicited in minute detail by Mr. Boyan Edwards, it appears that during the protectorate of Cromwell, the Spaniards had been guilty of several aggressions in the West Indies, and that the protector, in seeking redress, manifested a regard to justice by his moderation and temper. An appeal was at length made to force; and a powerful armament was equipped, which marched into Hispaniola, but succeeded at Jamaica, which was captured by the English forces in May 1655. At this time the whole number of white inhabitants on the island, including women and children, did not exceed 1500: and not one hundredth part of the plantable land was in a state of cultivation. The number of negroes, who had been first introduced from Africa by the Spanish settlers after they had exterminated the original proprietors, nearly equaled that of the whites, at the time of its capture. The principal exports of the Spanish planters, notorious for their loath and pecu-
furred the administration of justice in the island to remain on a very precarious foundation. In 1728 a compromise was happily effected. The assembly contented itself on the crown a flanding irrevocable revenue of $600, per annum on certain conditions, to which the crown agreed. The principal of these conditions are as follow: viz. that the quit-rents arising within the island, then estimated at $462, per annum, should constitute a part of such revenue; that the body of their laws should receive the royal assent; and that all such laws and statutes of England, as had been at any time elapsed, introduced, used, accepted, or received, as laws in the island, should be and continue laws of Jamaica for ever.

Jamaica is situated in the Atlantic ocean, about 4000 miles S.W. of England, having Hispaniola, at the distance of 30 leagues, to the E.; the island of Cuba, about the same distance, N.; the gulfs of Honduras, W.; and Carthagena, on the great continent of South America, S. at the distance of 145 leagues. The centre of Jamaica lies in about 18° 13' N. lat., and about 76° 45' W. long. The climate, though much mitigated by various causes, is extremely hot, with little variation from January to December; the days and nights are nearly equal, the longest and shortest day differing no more than about two hours with little twilight; and it is twelve at noon in London, when it is about seven in the morning in Jamaica. The north and south sides of the island, which are separated by a vast chain of mountains, extending from E. to W., differ greatly from each other. Columbus, when he first discovered Jamaica, on the northern side, and perceived that part which now constitutes the parish of St. Anne, was struck with admiration at the novelty, variety, and beauty of the prospect. At a small distance from the shore, the country rises into hills with gentle acclivity, which are separated from each other by spacious vales and romantic inequalities; and is beautifully covered with groves of pimento, forming by their deeper tints a charming contrast to the verdure of the subjacent turf. The soil is in general a chalky marl, which produces a clove turf, as smooth and even as the finest English lawn, and in colour much brighter. No part of the West Indies abounds with so many delicious streams; every valley having its rivulet, and every hill its cascade. On the southern side of the island the scenery is of a different nature; its predominant feature being grandeur and sublimity, whilst the other side presents variety and beauty. Amidst precipices and inaccessible cliffs, however, there are vast plains, clothed chiefly with extensive cane-fields. To the inequalities of surface that distinguish this island, it is owing that, although the foil in many parts of the island is deep and very fertile, yet the producive land is but of small extent, in proportion to the whole. That which is actually cultivated is of a middling quality, and requires labour and manure to make it yield liberally.

Jamaica is 150 miles in length, and at a medium about forty miles in breadth. Calculating from these data, the island, if it were a level country, would contain 3,840,000 acres; but allowing for that great part of it which consists of high mountains, and supposing, at a moderate estimate, the increase on that account to be 1/4th more, or 2,400,000 acres, the total is 4,080,000 acres. Of these no more than 1,907,589 were, in November 1789, located, or taken up, by grants from the crown; and consequently, upwards of one-half of the lands is considered as of no kind of value, the expence of taking out a patent being of no great account; and of the located lands, Mr. Edwards supposes that little more than one million is at present in cultivation. In sugar plantations, including the land reserved in woods, for the purpose of supplying flares, timber, and fire-wood, or appropriated for common pasturage, all which is commonly two-thirds of each plantation, the number of acres may be set at 630,000. Of breeding farms, called "pens," the number is about 400, and allowing to each 700 acres, the whole amount is 280,000; and the space allowed to the minor productions, as cotton, coffee, pimento and ginger, &c. including even the provision plantations, may be estimated at no more than one-half of the extent affixed to the pens. The result of the whole is 1,059,000 acres, leaving upwards of three millions an unimproved, unproductive wilderness. The mountains, however, are generally covered with extensive woods, containing excellent timber: such as the lignum vitae, log-wood, iron-wood, pigeon-wood, green-heart braziletto, and bully-trees, all of which are to a great degree heavy, as well as compact and impenetrable. Some of these are necessary in mill-work, and would be highly valuable in the Windward islands. Of softer kinds, for boards and single; the species are innumerable; and there are many beautiful varieties for cabinet-work; and among these we may enumerate the bread-nut, the wild-lemon, and the well-known mahogany. Jamaica is not only abundantly wooded, but well watered; the number of its rivers being reckoned at about 100. It has also a variety of medicinal springs. Formerly, it is said, the Spanish inhabitants had mines both of silver and copper; but the present occupiers employ their industry more profitably on the surface than in digging into the bowels of the earth. The most important of its present natural productions are sugar, indigo, coffee, and cotton. The several species of grain cultivated in this island are, maize, or Indian corn, producing usually two crops in the year, and sometimes three; Guineacorn, producing one crop in the year, planted in September, and gathered in January following, yielding from 60 to 80 bushels an acre; and various kinds of calavances, a species of pea, and rice, but in no great quantity. The island abounds also with different kinds of grafts, of excellent quality: the artificial grafts, called "Scott's grafts," grows spontaneously in most of the swamps and morasses of the West Indies; and it is so productive, that a single acre of it will maintain five horses for a whole year. The "Guinea-grafs" is next in importance to the sugar-cane, as the grazing and breeding-farms are chiefly supported by it. Hence arises the plenty of horned cattle, both for the butcher and planter; which is such, that few markets in Europe furnish beef of better quality, and at a cheaper rate, than that of Jamaica. Mutton also is cheap and good. The seeds of the Guinea-grafs were brought from the coast of Guinea, as food for some birds which were presented to Mr. Ellis, chief justice of the islands. The several kinds of kitchen-garden productions, that are known in Europe, thrive in the mountains of this island; and the markets of Kingston and Spanish town are supplied with cabbages, lettuce, carrots, turnips, parsnips, artichokes, kidney-beans, green peas, asparagus, and various sorts of European herbs, in the greatest abundance. Other indigenous productions that may be classed among the excellent vegetables, are plantains, bananas, yams of several varieties, calabah (a species of spinage), eddoes, cassivi, and sweet potatoes. Among the more elegant fruits of the island we may reckon the anna or pine-apple, tamarind, papaw, guava, sweet-sap, casseh-apple, ullard-apple, cocoa-nut, star-apple, granadilla, avocado-peach, hog-plum, pindal-nut, neflary, mammee, mammee-lapots, Spaniah goatberry, prickly pear, and some others, for which Jamaica is probably indebted to the bounty of nature. For the orange, the lemon, lime, shaddock, vine, melon, fig, and pomegranate, the West India islands are perhaps obliged to their
their Spanish invaders. The cinnamon has been lately introduced, and the mango is become almost as common as the orange. In 1773 a botanic garden was established in Jamaica, and in 1782 its valuable exotics were much increased.

This island is divided into three counties, viz. Middlesex, Surry, and Cornwall, which see respectively; and these three counties include twenty parishes, in which are eighteen churches and chapels; each parish being provided with a rector, and other church officers, and the presentation to each living being lodged with the governor or commander-in-chief. The supreme court of judicature for the whole island is held in the town of St. Jago de la Vega, the capital of the county of Middlesex, in which court the chief justice of the island presides, whose office is worth about 3000l. per annum. The affiliant judges are gentlemen of the island, commonly planters, who receive for their attendance no remuneration. From this court an appeal lies in civil actions for 500l. or upwards to the governor and council, as a court of error. Affitt courts are also held every three months, in Kingston for the county of Surry, and in Savannah-in-Mar for the county of Cornwall. The governor, or commander-in-chief is chancellor by his office, and prelates solely in that high department; he is also the sole ordinary for the probate of wills and granting letters of administration. The office of enrolments, or of secretary of the island, which is an office of record, is important and lucrative; it is held by patent from the crown, and exercised by deputation. Its emoluments exceed 600l. sterling per annum. The provost-marshal-general is also an officer of high rank and great authority, and held by patent from the crown. This acting officer is high-sheriff of the whole island, and his legal receipts have been known to exceed 7000l. sterling a-year. The office of clerk of the supreme court is also held by patent, and exercised by deputation: some years ago its value exceeded 9000l. currency. There are several other lucrative appointments, held by patent or commission; and it is computed that not less than 30,000l. sterling is remitted annually by the deputies in office within the island to their principals in the mother country. The legislature of Jamaica is composed of the captain-general or commander-in-chief, of a council nominated by the crown, consisting of twelve gentlemen, and a house of assembly, containing 43 members, who are elected by the freetholders. All bills passed in this assembly have the force of laws as soon as the governor's assent is obtained; but the power of rejection is still referred to the crown.

The revenues of the island are partly perpetual by an act of the year 1728, and partly annual, depending on grants of the legislature. The revenue law may raise about 12,000l. per annum, of which 8000l. is particularly appropriated, and the surplus is applicable to the contingent expenses, in aid of the annual funds. The governor receives 2500l. per annum out of the 8000l. fund; and a further salary of 2500l. is allowed upon him, during his residence in the island, by a special act of the legislature. The annual funds may amount to 70,000l., of which about 40,000l. is a provision for granting an additional pay to the officers and soldiers of his majesty's forces stationed for the protection of the island. The current coins in Jamaica are Portuguese pieces of gold, called the half-johannes, valued in England at 33s. each; which pays, if of full weight, at 55l. Spanish gold coins current are doublee at 1. 13s. 4d. each, and milled at 24s. 3d. Silver coins are Spanish milled dollars at 6d. 8d., and in proportion for the smaller parts of this coin: the lowest coin is called a bit, equal to about 5d. sterling. A guinea pays for 32s. 6d. The number of white inhabitants was computed in 1780 at 25,000; but having since increased, Mr. Edwards supposes that, including the troops and fire-fearing people, their number may be fixed at 50,000. The freed negroes and people of colour were computed in 1788 at 500 in each parish on an average; which makes 10,000 exclusive of the black people called Maroons. These amount to about 14,000.

Of negroes in a state of slavery, the precise number in 1787 was 110,834, and including those who are fraudulently not returned, this number may be augmented to 250,000. The whole number of inhabitants of every description is therefore estimated at 291,400. Mr. Edwards reports, from the books of the inspector-general of Great Britain, that the trade of Jamaica, in 1787, employed 400 vessels, containing 78,862 tons, navigated by 8845 men; that the total value of the exports from the island to various parts from January 5th, 1787, to January 5th, 1788, amounted to £3,356,425 17s. 5d.; and that the total value of the imports amounted to £1,936,232. 5s. 4d. or by certain allowances necessary to be made, to £1,988,018. 1s. 4d. sterling. Jamaica, says Mr. Edwards, had now nearly attained the merit of its proper. The total of sugar plantations in all the parishes of the island are stated by this author to have been, in 1780, 710, and the number of negroes employed in them 128,798. The number of its coffee plantations has very considerably increased; for in 1774 the export of coffee was 65,47000lbs., and in 1790, 1,783,740lbs. The exports consist of sugar, rum, molasses, pimento, coffee, cotton wool, indigo, ginger, sugar, tobacco, mahogany, logwood, hides, and several miscellaneous articles. The imports conflict of British manufacturers, foreign merchandise from Great Britain, salted provisions from Ireland, formerly negroes from Africa, salted cod, &c. from the British colonies in America; from the United States, Indian corn, wheat flour, rice, lumber, slaves, &c. In British ships, from Madeira and Teneriffe wine. Mr. Edwards gives the following statement of the value of this island, considered as British property: 250 negroes at 50l. sterling each, amounting to 125 millions; the landed and personal property to which these negroes are appurtenant, (including the buildings,) are moderately reckoned at double the value of the slaves themselves; making 25 millions in addition to the 13 millions 500 thousand before stated; and in further addition the houses and property in the towns, and the vessels employed in the trade, are valued at one million 500 thousand pounds more: amounting in the whole to 59 millions of pounds sterling. Edwards's Hist. West Ind. vol. 1.

JAMAICA, a township of America, in Windham county, Virginia, watered by several branches of West river, and containing 263 inhabitants.—Also, a small town and capital of Queen's county, New York, on the W. part of Long island, containing a Presbyterian, Episcopalian, and Dutch church, an academy, and nearly 100 dwelling-houses: 12 miles E. of New York city; the whole township contains 1661 inhabitants.—Also, a town of Africa, in the island of York, built by a Middotio, the son of an Englishman, where the English have a factory.

JAMAICA Peppers. See Pimento.

JAMAICA Wood. See Brazil.

JAMALGONG, a town of Bengal; 42 miles S.S.E. of Dinagepur.

JAMAMA, or ISRAM, a town of Arabia, the capital of a district in the province of Nejd, situated on a river, which runs into the Persian gulf, and famous for being the birth-place of a prophet named Melechana, who visited the days of Mahomet. N. lat. 21° 25' E. long. 60° 8'.

JAMANASSIRO, a town of Japan, in the island of Nippon; 65 miles N.W. of Jedo.
JAMARD, in Biography, an ingenious and worthy ecclesiastic, who was, before the Revolution, a canon regular of St. Genevieve, prior of Roquefort, member of the Academy of Sciences, Belles Lettres, and Arts at Rouen; and who published in 1769, at Paris, in 8vo. "Recherches sur la Theorie de la Musique," or an Enquiry into the Theory of Music. The work is purely theoretical, and dully confined within the limits of harmony, or division of the musical scale. The author has, unfortunately, given offense to the patriotic musicians of France, still exclusive admirers of Lully and Rameau, by the following reflection: "It is astonishing that the Italians, who adhere strictly to no regular system or theory of sound, should compose better music than we do, who are in possession of such excellent principles of harmony." But M. Laborde, strongly attached to the old school, by no means admits the fact. In the first place, so far from granting that the Italians produce better music than we (the French) it is certain, on the contrary, that ours, with respect to harmony, is much superior to that of the Italians, and that we allow their superiority in nothing but the musical drama, or opera, which is not tied down to such rules as music properly so called, nor regarded in general as amenable to the laws of counterpart.

"In the second place, it is necessary to observe, that almost all the Italians compose by rote and by feeling, according to the method of their several schools. Very few of them have ever studied the theory, or have the least idea of the principles on which it is founded. We must allow, however, that this is the case with most practical musicians, they seem to think theory a science totally independent on practice. There is no practice, however, safe or exempt from error but by the knowledge of the principles of harmony, and the rules that flow from those principles. We will allow, if you please, that the Italians are superior to us in melody; but they must grant that we are their masters in harmony, and that we write in a manner much superior to them in accuracy, purity, and elegance." All this is very fine and honourable to France, but will the rest of Europe subscribe to M. Laborde's decisions? and will it be believed that no good music ever has been composed or can be, by performers unacquainted with Ramcza's system of the fundamental base? or that all the great masters of Italy who have produced such admirable works were ignorant of harmony? Does not the great Molière and Rameau in this be justified? This ingenious author has not only pushed calculation by thus the division of the monochord into all the diatonic, chromatic, and enharmonic intervals; but to the most minute shades of sound possible; even to the warbling of birds, the sliding of the finger up and down the string of a violin, or the inaudible tones of speech. The work that can be said, perhaps, of this labour is, that its use and application are not obvious. But a serious objection by nice ears will be urged against the author's making so imperfect an instrument as the French horn the guide and umpire of the diatonic scale, of which the 4th and 5th are so intolerably false and out of tune, that "the ploughman whistling over the furrow'd land" would not deform his wild melody by such a false. But though the adable system of M. Jamard may be immovable and impracticable, as much ingenuity and science are manifested in these calculations as could possibly be expected from a mere mathematician, totally unacquainted with practical music and its effects.

JAMAS, in Geography, a town of Japan, in the island of Ximo; 12 miles S.W. of Udo.

JAMATA, a town of Japan, in Niphon; ten miles W.S.W. of Jedo.

JAMBA, in Ancient Geography, a town of Asia, in Babylonia, according to Ptolemy, situated near a marsh towards Arabia Deleria.

JAMBA, in the Mythological Romances of the Hindus. This is the name of a bear with whom Krishna and others of their deified heroes had adventures; ridiculous, if taken literally, but reasonably imagined to be merely a veil for physical or scientific facts. See Jambavan.

JAMBAVAN, or Jambhuwan, the name of a bear celebrated by Viñhû, as related in the legends of the Hindus, for the purpose of aiding Rama in the wars of Lanka or Ceylon. On this occasion most of the gods and goddesses of the Hindu pantheon were called upon by Viñhû to assist Rama, himself indeed incautious, against the giant king Ravana, as described at great length in that curious poem the Ramayana, by Valmiki, which has not yet been translated. See Ramayana and Ravana.

JAMBAVANTA. In the Sri Bhagavata, or Life of Krishna, eminated by the Hindus as the eighteenth Prana (see Pavana), a number of adventures are related in which a bear acts a conspicuous part under the name of Jambavan. In Viñhû's anataara, or incarnation in the person of Rama, a bear likewise under nearly the same name is introduced. Some astronomical allusions are imagined to be hidden under these viyan allegories. Krishna is the fun, he attacks and overcomes the bear, retiring with the daughter of his adversary; this may refer to the fun's approach to, and reeding from, the northern tropic; Jambavan being, it is supposed, a perfonification of Urfa major.

JAMBAVANTI, a female bear, daughter of Jambavan, espoused by Viñhû, as related with many similar apparently idle tales, in the Pranas and other romances, sacred and profane, of the Hindus.

JAMBEAUX, among our Old Writers, armour for the legs. The word is French, from jambe, the leg.

JAMBEC, in Geography, a town of Sumatra, which is the capital of a state, and situated on a large river, both of the same name; the town is distant from the sea on the eastern side of the island about 60 miles. This was formerly a place of considerable note, and both the English and Dutch companies had establishments there. The trade consists in gold dust, pepper, and canes, but it is now esteemed of little importance; the gold being mostly drawn to the western coast across the country. S. lat. 1° 24'. E. long. 103° 39'.

JAMBER, a small island in the Atlantic, near the coast of Africa. N. lat. 10° 21'.

JAMBIA, in Ancient Geography, a town of Arabia Felix, on the Arabian gulf, according to Ptolemy. It was situated near the Eutanic gulf.

IAMABIC Foot, or IAMBUS, in Metro, consists of two syllables; the first, short; the second, long /*; as in the verses around.

"Symphyna longa brevi jucunda vocatur iambus, Poes. citus." Hor de Art. Poet. 251.

Several derivations of this word are given by ancient authors, but none of them have much probability. (See Suid. on Hephæstion, p. 157 and 168; ed. Gaisford. Etym. Magn. Sch. on Nicander. Euthal. On od. 11. p. 168. Diodores, p. 475.) The most probable one is from iambe, to aim at, or attack. Ariostio (Poet. § 4. Winz. & Strabo (I. 9. § 10) derive it from apa, to fastenize; but I cannot find that this word was ever used before the invention of iambic verse; or that in later authors it was ever used without some reference to it. When Gurgani said that Plato αυτάς εἷς ἐπιστήμης ονομάζεται, he meant that he could
IAMBIC VERSE.

could defame as well as a writer of iambics; and with the fame allusion he called him another Archilochus. (See Athen. 11. 595. d.) The passage in which Ἰαμβική ἀριθμομετρία occurs in Aristot. Poet. (§ 22, see Tyrtewitt’s note) has been misunderstood by all his commentators. It should be read Ἐπειδή τοῦτο καὶ ἐπειδὴ τοῖς τρίτοις αὐτὸς ἔδωκεν Ἕρωδιος τὸς Ἀριστοτέλης ἐπιβεβηκότα, not Ἐπειδὴ τοῦτο καὶ ἐπειδὴ τοῖς τρίτοις ἔδωκεν Ἀριστοτέλης ἐπιβεβηκότα, as Plutarch quotes, if τὴν ἐπιβεβηκότα ἔδωκεν Ἀριστοτέλης ἐπιβεβηκότα in ἐπιβεβηκότα τὴν ἐπιβεβηκότα, that is, having made an iambic verse in the very expression. It is more probable, therefore, that Ἰαμβική ἀριθμομετρία was derived from the verse, than the verse from it.

Iambic Verse is that which consisted principally of iambic feet. The Greeks used a great variety of forms of this verse, either separately, or intermixed with other verses. (See Schol. on Hesych. p. 167.) It was measured by dipodie or double feet. When they used therefore a single iambic foot as a verse, it was called

Iambic Monometer Brachycaesitic, for which an end of two syllables, except a trochee. Soph. Ξεδ. Col. 117. 149. Εἰ. 876. 865 ed. Brucke.

An Iambic Mon. Cætalic, composed of an amphibrach or a bacchius. (Soph. Αἰ. 873. 873. 1205. Εἰ. 1237. 1237. Ξεδ. Col. 173.) This was sometimes intermixed with iambic trimeters. Soph. Ξεδ. t. 1468. Τρ. 885. Ξεδ. c. 1271.

Iambic Monometer called also an iambic δύο, composed of two iambic feet; and admitted, instead of the first iambus, a trisarc, or a propeeke, or a δύοτικός, or an anapæst. Eur. Χρ. 312. Or. 979. Soph. Εἰ. 1273. 1232. Άει. Συμμ. Περ. 1045. (See Burney’s Pref. to Άει. p. 16.) Aristoph. Νυβ. 1107. Άε. 276. It is prefixed by Αιμβο- phrases, (Συμμ. 380, 455, 930.) to an iambic diameter, used at the end of a cell of iambic dimeters.

Iambic Monometer Hypercaesitic or Iambic Pentamerinus, admitted the same varieties in the first foot. Eur. Ηχ. 919. Soph. Αἰ. 599. Άει. Περ. 641. (See Burney, p. 25, and 80.) The last syllable was either long or short.

Iambic Dim. Cat called by the Scholiast on Nicander Heniambics. (Gaisford, p. 246.) Soph. Εἰ. 1241. 1262. Aristoph. Άε. 1233. He often closes a cell of dimeters with this verse (Εἰ. 381. 456, 940.), and often intermixes them. (Αἰ. 1010. 1039.) In the second place he generally prefers an iambus (Herm. de Metr. p. 151), but he has a trisarc in Άε. 1039; and an anapæst, Νυβ. 1104. The Anacerontic verse is referred to Hesychius to this metre. It consisted of two different syllables; in one of which the first foot was always an anapæst; in the other, either an iambus or a propeeke; and in his genuine odes, no other variety was, I think, admitted. The last syllable was common. Both of these have been confuted by others as Iωάδι αἴστερ, with an anacrusis of one or two syllables. (See Herm. de Metr. p. 548.) This metre occurs with an anapæst in the first place, in Eur. Χρ. 493–511. Soph. Πν. 1175. 17. Εἰ. 1657. 8. 1979. 80.

Iambic Dimeter.—The tragedians admitted an iambus or a propeeke indirectly in the first and third places of this verse, and a trisarc in the third place, and a pyrrhic in the last (Soph. Αἰ. 333–8. 872–4. 672. 3. 963. 4. Εἰ. 978. 978. 982. Άει. Προμ. 159–161. 178–180. Εἰ. 982, et seq. Πινδ. Ο. 4. Εἰ. 3. Νυβ. 11. 1.) : but when many of these verses were united together in a iambic, as was often done by the writers of comedy, the measure was continued to the end of the cell; the last syllable, therefore, was not common, but the fourth foot admitted the same varieties as the second; according to this scheme:

<table>

Iambic Trimeter, is the metre of this kind most commonly used; and it consisted of three iambic dipodies.

"Iambus ipse sex enim locis metat
Et inde nomen indicat et Semnario;
Sed ter futurum; hic Trimetros dicturus,
Scandendo bimis quod pedes conjungimus."

Terentianus Maurus.

It is so nearly allied to prose, that Arisotle (Rhetor. 3. 9. 3. 8. 4. Ποετ. 4.) and Demetrius Phalarus (§ 43, see also Περ. 189) have observed, that many iambic verses were uttered in common conversation; and they are frequently to be met with in the works of Greek prose authors. From this circumstance it was well suited to the ferio pedefris of satire, to which purpose it was applied by its inventor Archilochus. (See Hor. Art. Ποετ. 79. and Od. 1. 16. 2, and 22. Επίλ. 1. 19. 24.) The same circumstance made it also peculiarly applicable to dramatic composition.

"Hunc Socci cepere pedem, graveque Coturni,
Altemnique aptum femeronibus, et populares
Vincitatemque ferepit, et nutum rebus agendis."

Hor. Art. Ποετ. 80.

See also Cicer. Οra. 191.

A pure iambic verse would consist of fix iambic feet; as

Παντοτε τοιαύστερον, πολιτικὸν

Dion. Hal. de Compos. § 17.

but necessity obliged the first writers to admit other feet, which was chiefly done in the fifth, third, and fifth places.

"Tardior ut paulo graviorque veniret ad aures,
Spondeos stabiles in jure paterna receptis,
Commendus & patiens; non ut de fede secunda
Cedere, aut quarta focialiter."—

Hor. Art. Ποετ. 254.

The few fragments of Archilochus and Solon which remain, have a propeeke in the first and third places much more frequently than an iambic; and they seem to have used them indifferently in the fifth. Archilochus also affords two

influences
IAMBIC VERSE.

instances of the resolution of the iambus into the tribrach in the second; and one, of the admission of a dactyl into the first place. These licences were afterwards generally used by the tragic poets, who admitted the following variations into their verse:

```
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
```

Many critics, among whom are Muirgrave (on Eur. El. 23) and Brunck (on Soph. Ed. c. 371 and 1169, and Phil. 491.), have thought that the anapest was admitted in the second and fourth places; and it was long the universal opinion that it was allowed in the third and fifth; and there are several verses in the printed editions which seem to confirm this opinion; but in proportion as more and better manuscripts have been collated, the number of these places has been diminished, and the anapest has been confined to the first place, where Aeschylus and Sophocles have been careful to include it in a single word, and Euripides either in a single word, or in a preposition and the word which it governs. (Morer. Proefol. p. 11. 19. Porfom. pref. ad Eur. Hec. Hermann. pref. ad Eur. Hec. p. 33. 38. and 53.) In proper names, such as Εξαιρος, Αριστον, which could not otherwise be used in an iambic verse, greater licence was allowed; and an anapest was admitted in any place but the last. And this liberty has been sometimes used in names which did not necessarily require it, as Μιχαλε, Αριστον, but care was taken that the whole anapest should always be included in the name. Porfom. pref. p. 20. Herm. pref. p. 65.

It has been observed by Mr. Porfom, to whom we owe the first notice of some of these rules, and the establishment and confirmation of others, that in the tragic writers, when an iambic trimer ends in a trilabell, the fifth foot is very rarely a spondeon, unless the last word but one be a monyllable. It is the same, if the verse ends with a trochee and a spondeon; or with a long syllable and an iambus, if the long syllable is a preposition, or an article, or any syllable particularly belonging to the following word; but if the long syllable is an enclitic, or a particle referring to what goes before, it may then make part of a spondeon. (Porfom. pref. p. 30. Herm. on Eur. Hec. 341.) This rule is strictly observed also by Lycophor. Mr. Porfom (see note on Eur. Phoc. 1464.) has observed that and never makes the latter part of a spondeon in the fifth foot of a tragic iambic. Perhaps he overlooked Soph. Phil. 961; and he seems himself to have admitted a conjecture of Caunter on Aesch. Suppl. 4. 11, which introduces it. The comic poets used much greater licence, and the form of their verse was

```
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
/  /  /  \
```

The reason of these licences will be more clearly seen, if we consider that in the iambic trimer there are three Εξαιρος, or iuctus, or emphases, which are here marked, the first of which took place on the long syllable of the first iambus, or its equivalent. As the rhythm was principally directed by these, it may be considered as beginning at the first iambo; and the verse will then become a trochaic trimer catalectic, in this form

```
\[\begin{array}{cccccc}
\text{\_} & \text{\_} & \text{\_} & \text{\_} & \text{\_} & \text{\_} \\
\end{array}\]
```

(See Bentley on the Metres of Terence; Dares Mife. Crit. p. 189; Herm. de Metr.) The syllable before the first iambus, when the rhythm had not yet commenced, was differently either short or long, and sometimes two short ones were admitted. In the remaining part of the verse, as two short syllables were considered as equivalent to one long, the trochee was used almost indiscriminately instead of the trochee, except in the fifth foot, where the tragedians seldom resolve the long syllable, and never, if it is preceded by a long one. The first foot of each trochaic dipodia (either or) being most distinctly heard, was preserved purely by the tragic poets, but in the familiar style of comedy, the dactyl was sometimes substituted for the trochee, which would produce an anapest in the second place of the iambic verse. In the next foot, at the close of the dipodia, a spondeon or a trochee was indifferently used by the tragedians, and a dactyl by the writers of comedy.

Daves (p. 350.), and Morell (p. 12.), have observed that Aristophanes avoids putting an anapest immediately after a dactyl or a trochee in an iambic trimer. Hermann (de Metr. 150-162) produces many instances (to which more might be added) of an anapest after a trochee, which he considers as a proceleutmatic, formed from the resolution of the long syllable of an anapest and an iambus; but they are probably corruptions, and may be removed without difficulty. It may be observed also that when an anapest is admitted into the fifth place by Aristophanes, it is included within one word; or contains the whole of two, as of a preposition and an article; or is entirely comprehended within the last words of the verse; but the beginning of the anapest is never joined in the same word with the fourth foot, or any part of it. In Brunck's edition there are only seven exceptions to this rule; two of which (Ach. 800. 962.), are occasioned by the marks of digraphs improperly placed, and the other five (Plut. 932; Nub. 258. 1192. 1458; Av. 925.) may be very easily corrected.

The caesura of the iambic verse takes place at the end of the first trochaic dipodia, that is, in the middle of the third foot; and a new trochaic order then begins. The constant observation of this caesura would make the verse too uniform and monotonous; it is therefore very frequently neglected: for I would not consider it a caesura, the termination of a word in the middle of the fourth foot; since the first foot of the trochaic order which succeeds would then frequently be a spondeon. As Εξαιρος Ιακυνθος, Εξαιρος μαρα- "Εξαιρος Ιακυνθος. Instead of either of these, a division sometimes takes place after an enclitic at the end of the third foot; but otherwise the tragedians very rarely make the third or fourth foot a single word; and carefully avoid including them both in one word; as that would destroy all perception of the trochaic order of the verse. Bentley, Herm. de Metr. p. 147; and on Eur. Hec. v. 71; Porfom. pr. to Hec. p. 24; Guisford or Hesperus. p. 259.

The words which cannot begin a sentence, cannot stand at the beginning of an iambic verse (Bentley on Menand. p. 108. Monthly Rev. June, 1785, p. 424.), and the arsis is very seldom admitted on an enclitic (Porfom. p. 16.), or on the last syllable of a word of more than two syllables (Daves, p. 351, 350.) though to this a few exceptions may be found. Aris. Lyf. 750. 744. Rat. 785.
IAMBIC VERSE.

In the satiric fable the fame licence was probably allowed as in the comedies. In the single drama which remains, a dactyl is not to be found in the fifth place, nor an anapest in the third; unless Periion's conjecture on v. 28 be admitted.

The earliest iambographi, or writers of iambic verses, Archilochus, Solon, and Simonides, used a spondee or an iambus indifferently, as has been before observed, in the odd places; but were very sparing in the use of feet of three syllables. The "Pom upon Women," which was written perhaps by some Simonides of more recent date, has a trisyllabic verse in the first, second, and fifth places, and an anapest in the third. Lycurphon has admitted a trisyllabic verse in the third place (v. 1164. ed. Reichard, and fourth (700. 99.), and with part in a proper name in the second and fourth (520. 874. 1436). He has ten or eleven dactyls in the third place, but an anapest only in a proper name (720. 970. 972.); for in v. 634. it should be expunged. See Herm. de Metr. 150, who affirms that the iambographi never admit a dactyl or anapest. Brunnec. Soph. Ed. c. 371. Porion, pref. to Hec. p. 10.

Another kind of iambic trimeter much allied to this, was the Chelamibi, Claudius, or Seaccom, called also Hipponaeus, from Hipponax, who is said to have first used it. He applied it to the same purpose of severe satire, and bitter invective, as Archilochus. (Leonid. Epigr. 97. Alexius, Ep. 18. Philipp. Ep. 83. Demetr. Phial. § 525. Euthath. on Od. 11. p. 1684. Cie. de Nat. Deor. 3. 38. Hor. Epod. 6. 14. Ovid. Ibis. 523.) The distinguishing characteristic of it was a spondee in the third place. The varieties which it admitted, as far as we can collect from the fragments which are extant, were according to the following scheme.

\[ \frac{\text{1st place: spondees}}{\text{2nd place: spondees}} \]
\[ \frac{\text{3rd place: spondees}}{\text{4th place: spondees}} \]

Of these the anapest was very rarely used, and the dactyl not frequently. (Bentley on Philaris, p. 433-6. Gaisford on Heph. p. 251-S.) Thence verses were sometimes called Mimambli. (Terentianus Maurus. A. Cell. 15. 25. 26. 10.) Joh. Stobæus has preserved several of them from *Hercules in Hesiamus*, which ought perhaps to be changed to *Miniambli*. (See Cafaub. on Athen. 1. cap. 17.) This metre was sometimes used by Callimachus. See his Fragments, collected by Bentley, 82-98.

When the fifth foot was also a spondee, the verse was called iypheside. (See Tyrwhitt's Babrius, p. 13.) This was principally used by Anaxias (or, as he is called by Athenaeus, Anaxias), but was occasioned intermixed with the other by Hipponax and Babrius. See also an epigram on Hipponax, by Theocritus.

Iambic Trimeter Hyperca. Ariloph. Lyfithr. 1207. Theop. 988. It occurs in *Aesch. Chorip. 321. 322*; according to Burney's arrangement; and in *Tind. Ol. 3. 6. and Nem. 9. 11* according to Hermann.

Of Iambic Tetrameter Brachycat. which is mentioned by the Icholaia on Hephastion, I find no example.

Iambic Tetrameter Catalan, called also Hipponaëtus. (Sch. on Ariloph. Plut. 253. Hephastion. Marius Victorinus. See Gaisford, p. 246.) This was very frequently used by the comic writers, and had a pause at the end of the fourth foot, though the word frequently did not end with it. It admitted, in the first, third, and fifth feet, the same varieties as in the same feet of the comic trimeter; and, in the second and fifth, the same as in the second and fourth of the other. The fourth foot could only be an iambus or a trisyllabic; and in the seventh an iambus only was allowed, except in the case of a proper name, when an anapest was admitted in either place. Ariloph. Ran. 905—975. Nub. 1334—1624. Theor. 531—573. Lyfithr. 539. 540. Porion, pref. to Hec. p. 25. Monthly Rev. Sept. 1759. p. 255. note.

Iambic Tetrameter. A verse of Aëcim in this metre is quoted by Hesychius, and his Scholiast. Hesychius prefixed to the name, where it is said to have first used it. It was not used by the Greek dramatists. Hermann. p. 181. Gaisford. p. 245.

Iambic Tetrameter Hyperca. The Scholiast on Hesychius produces a verse in this metre, and says that the measure of iambic verses was extended still further; but the examples which he cites are made up of shorter verses of Archilochus joined together.

The Romans do not appear to have made use of so great a variety of iambic verses as the Greeks. I will enumerate those which were most commonly used by them.

Iambic Monometer Hyperca. occurs occasionally in the tragedies which are ascribed to Seneca. (Ed. 411, 415, 732.) An anapest and a spondee were used in the first place:

Iambic Dimeter. Seneca uses a syllable of these verses in: Agam. 750—784. In the first foot he has admitted a spondee and a dactyl in the third, a spondee; and the last syllable is common. He has a number in the first and fourth, Ed. 414. Plautus (Mort. 1. 2. 25. 26. 49. 50.) and Terence (Andr. 1. 2. 3. 1. 2. 3. 5. 8. 17. 3. 3. 5. 3. 4. 26.) use a spondee and an anapest in every foot but the last, and a dactyl in the two fifth. Hermann (de Metr. p. 146.), Virgil (Catal. 5.), Horace (Epod. 1. 10.), Martial (1. 59. 3. 14.), and Seneca (Med. 771—786.), have used this metre alternately with the iambic trimeter. Horace (Epod. 14. 15.) has intermixed it with hexameters, and Martial (1. 62.) with hexameters. Besides the iambic and spondee, an anapest and dactyl are admitted in the first place by Martial, and a trisyllabic by Horace, who once uses a dactyl also in that situation. The second was always an iambus or trisyllabic. The spondee was the most common foot in the third, but an iambus is occasionally used, and Martial and Seneca have sometimes an anapest.

Iambic Dimeter Hyperca. This is the third verse of the Alcaic ode, which Horace always uses in this form, preserving a spondee in the third place: 

Iambic Trimeter Brachycat. Seneca (Ed. 710, 720, 731, 733, 736. Agam. 596. He admits a spondee and an anapest in the first place, and a spondee in the third, fourth, and fifth.

Iambic Trimeter Catalan. Horace uses this metre (Od. 2. 18.) with a caesura in the middle of the third foot. As it follows a trochaic trimeter this foot and the syllable preceding the caesura is either long or short. This verse may be considered as an anasternete confining an iambic pentameter, and an iambus. A spondee was allowed in the first place, and a trisyllabic in the second. In Od. 1. 4, the same meter occurs with the same caesura, and a long syllable always before it. As it is joined with an anasternete, composed of a dactyl, tetrameter, and an iambus, it may properly be considered as spondee or trisyllabic, an anasternete here also.

Iambic Trimeter. In the tragedies of Seneca, an iambus, trisyllabic, spondee, dactyl, anapest, and proceleuses were admitted in the first place, and the first foot of the iambus in the third, which received an anapest also, though rarely, and only:
only in words of four syllables. In the second and fourth, an iambus, or a tribrach only, was admitted. In the fifth place an iambus is found only in five verses, and a dactyl only in four; the verse ending, in both cases, with a word of four syllables; and a tribrach only in three, and contained by one word. (See Aventius.) An anapest and a freche were admitted indifferently in this place; but it is observable that the anapest is always contained in one word, with or without an elision of the last syllable, except in eight places where a pyrrhic is found followed by 5th, or 6th. The only exceptions to this rule are in Herc. Oct. 406. 757, and Oct. 393, which may be all made regular by an easy transposition. The anapest in nexit guil, which occurs five times, is not an exception, as that expression was considered as one word.

Plautus and Terence in the first four feet use an iambus, spondee, dactyl, tribrach, anapest, and proceleutic. In the fifth, a spondee, dactyl, and anapest. The third and fourth feet were very rarely allowed to be single words, which would have thrown the artis on the last syllable of the words; and whenever this happened, they were careful to have the preceding syllable short. (See Bentley on Terence.) Phaedrus uses the same licence as the comic writers, excepting that he does not admit a proceleutic.

Catullus in Carm. 4. 29; Virgil in Catil. 3. 4; and Horace in Epod. 16. (where he uses this metre alternately with hexameters), admit no foot but the iambic, except a pyrrhic at the end, from the last syllable being common. In other places where this verse is used alone, as Catullus, 52; Horace, Epod. 17, or with alternate dimeters, a spondee, anapest, and dactyl were admitted in the first and third places; a spondee and anapest in the fifth; and a tribrach in the second, third, and fourth.

The reason is used not unfrequently by Catullus; by Virgil, Catil. 2. 7; and by Martial very frequently. Virgil admits no foot of three syllables, and Catullus very rarely. Martial has the same variety as in the regular trimeter in the four first feet; and in the second and fourth he admits also occasionally an anapest. In this metre the fifth foot, among the Latins, was almost invariably an iambus, though a spondee may be found there in Martial. 1. 67. 13.

Iambic Tetrameter Catall, called also Septenarius. Catullus. 29. Terence, Andr. 4. 2. Enn. 3. 4. 3. 5. Hor. 2. 5. 2. Plant. Ani. 3. 3. Mill. Gl. 2. 4. Mort. 1. 3. In all the feet of this verse, but the fourth and seventh, the same variety was allowed as in the trimeter. In the fourth, Bentley (see Hec. 2. 202) admits in Terence only an iambus; but in Eun. 3. 5. 57. his own edition has an anapest, and in Hec. 3. 2. 24, a proceleutic, in that situation. Plautus has sometimes admitted in the fourth a tribrach and an anapest, and sometimes seems to have considered the verse as an asynarcte, and therefore admits a pyrrhic and an hiatus before the caesura. (Ani. 3. 3. 61.) In the seventh a spondee, dactyl, and anapest were used. See Herrn. de Metr. p. 177—181.

Iambic Tetrameter. This metre was also used very frequently by the comic poets. The caesura was either at the end of the fourth foot, or in the middle of the fifth. In this latter case, all the six feet first admitted the same variety as the comic trimeter. In the former the fourth foot was generally an iambus. The seventh foot might be a spondee or an anapest. The eighth was always an iambus. (Ter. Andr. 1. 2. 1. 3. Eur. 3. 5. 5. Phor. 2. 1. Plautus, Baccidae. 4. 9. Amphit. 3. 4.) The verses quoted by Cicero (Tusc. 1. 44.) from an old tragic poet, and which he calls Septenarius, were referred to this metre by Scaliger, Gehr. Volfinus, and lately by Herrmann. Bentley was of opinion that this verse was never used by the Latin tragedians. See Herrn. de Metr. p. 181—186.

N.B. The editor is indebted for the two preceding valuable articles to the Rev. Mr. Adams, vicar of Helston, Ellys.

As a poetical foot consists of a certain number of syllables which constitute a distinct part of a verse, so a bar of an air in music contains a certain number of notes of different lengths which are reducible to long and short syllables; an hemistich verse consists of six of these feet, a pentameter of five; an iambic foot has one short and one long syllable; and a dactyl one long and two short syllables, as θέας, πόρες, ἀμας.

Re-turn.

In ancient music, says Rouelle, there were two kinds of iambic verse, one of which was only rected to the found of instruments, whereas the other was sung. It is not easy to comprehend what effect the accompaniment of instruments could have on simple recitation; and all that we can reasonably conclude is, that the most simple manner of pronouncing Greek poetry, or at least iambics, was to musical tones, and very much resembled singing.

IAMBICE, in the Physical Injuries of the Ancients. Among the stringed instruments of the ancients mentioned by J. Pollux, we find one called iambic; and Muñonius, "de luxu Graecorum," says that it was a kind of triangular cithara, invented by Ibycus.

JAMBLICUS, in Biography, an ancient philosopher, who was a native of Syria, and educated at Babylon. Upon Trajan's conquest of Assyria, he was reduced to a state of slavery; but recovering his liberty, he afterwards flourished under the reign of the emperor Antoninus. His treatise in the Greek language, entitled "Babylonica de Simonidis et Rhodanis Amoribus," and confiling of 16 books, is said to have been lodged in MS. in the library of the Ecleial, and destroyed by fire in the year 1671. A fragment of it was preferved by Leo Alatus, accompanied with his own Latin version, in his Selections from the MSS. of Greek Rhetoricians and Sophists, Rome, 1641, 8vo.

Jamblichus was also a native of Caledos in Cæcilia- Syria, and flourished about the beginning of the fourth century. He received his first instructions from Anatolius, president of the Peripatetic school at Alexandria; and afterwards became a disciple of Porphyry. He was eminently versed in the mysteries of the Platonian system, and taught it with such reputation and success, as to attach to his school a great number of disciples. Although he was much inferior to Porphyry in eloquence, he commanded the reverence of his followers by high pretensions to theological powers. In the exercise of these powers, which he professed to acquire by an intercourse with invisible beings, he affirmed the credulous, and obtained the name of "the most divine and wonderful teacher." His reading was extensive, but his style was inaccurate and inelegant; and he took great liberty in borrowing from others, and particularly from Porphyry. This charge of plagiarism is alleged against Jamblicus by Koller, Volfinus, Gale, Motheim, and other learned men; but Dr. Lardner does not perceive any ground for it. This impartial and candid writer is of opinion, that Porphyry and Jamblicus found the same stories in authors.
JAM

thors more ancient than themselves, whom they both transcribed, and sometimes almost word for word. He adds, that most of the things related by these two authors concerning the wonderful works ascribed to Pythagoras are so trifling, and so manifestly fabulous, that he cannot believe they intended to oppose them to the miracles of Jesus Christ. The miracles of our Saviour, says Lardner, are all great and awful, related by credible witnesses, with all the circumstances of credibility: the trifling and fabulous accounts of Pythagoras cannot be set in competition with them. It is sufficient disparagement to those proud and learned philosophers that they gave credit to the Pythagorean fables. We need not reproach them with an intention to oppose them to the miracles of Jesus Christ. “The Life of Pythagoras”; “An Exhortation to the Study of Philosophy”; “Three Books on Mathematical Learning”; “A Commentary upon Nichomachus”; “Institutes of Arithmetic” and “A Treatise on the Mysteries of the Egyptians, Chaldean, Assyrians”; are all the writings of Jamblicus now extant. The most esteemed editions of the above-mentioned works are those “De Myth. Egypt. Chald. et Assyri- necon et alii Tractatus Philopothicos,” printed by Aldus, at Venice, 1497, fol.; “De Myth. Egypt. necon Per- phyrii, Epil. &c. Gr. et Lat. ex Interpretatione et cum Notis Thoma Gale,” Oxon., 1678, fol.; “De Vita Pythag. Liber Gr. et Lat. ex emendatione et cum notis Ludolphi Kufferi,” Amster., 1707, 4to. From St. Jerome we learn that Jamblicus wrote copious comments on the precepts of Pythagoras, commonly called “the Golden Verles”; and the emperor Julian, who holds him in equal estimation with Plato, cites a treatise on the fun, from which he has made many extracts. Fabricius mentions another work of Jamblicus, not now extant, entitled “Of Images”; or “Of the Divinity of Images” of which Phocius has given some account. The design of Jamblicus, it is said, in this work, is to shew the divinity of idols, which he calls images, and that they are filled with the divine presence, and are fallen down from Jupiter, &c. In support of this opinion he relates many incredible stories. This work of Jamb- licus is confuted by Philozenus. The time and place of his death are uncertain; but there is reason for believing that he died before Constanine, and probably about the year 333.

Jamblicus, another Platonic philosopher, who was a native of Apamea, in Syria, flourished during the reign of the emperor Julian, who was much attached to him, and very freely corresponded with him. This philosopher is said to have been poisoned under the reign of the emperor Valens. This Jamblicus has been confounded with the former by many writers, though they lived at very distant periods, and the works of the one have been ascribed to the other. This Jamblicus was the friend of Alypius, wrote with him on the subject of music, and composed the history of that great musician’s life.

JAMBICI SAL, in Medicina, a kind of felt prepared with fal ammoniac, and several aromatic ingredients, such as pepper, ginger, thyme, origanum, and the like; it has its name from its reputed author Jamblicus, and is supposed by many old writers to be an excellent medicine for concocting the crude humours, and gently producing frots. It was taken faithing in the quantity of half a spoonful, either alone or in a poached egg, or mixed with any liquor. JAMBON, or JANO, in Geography, a sea-port town of Arabia Felix, in the province of Hedgas, on the coast of the Red sea; 72 miles S.W. of Medina. N. lat. 24° 5'. JAMBOLIFERA, in Botany. See Calyptranthes. JAMBON, in Geography, a river of the island of St. Vincent, which runs into the sea; five miles S. of Young Point.

JAMBO, in Natural History, a name given by authors to a kind of sea-fish, resembling a ham of bacon. It is a species of pinna marina. JAMBOS, in Botany. See Eugenia. JAMES, among Carpenters and Bricklayers. See JAUM. JAMBUS, in Ornithology. See COLUMBA JAMB. JAMBU, the name of a Brazilian species of partridge, of which there are two species. They are of a dusky yellow colour, and are equal to the European partridges in the delicacy of their taste. JAMBUS, in Greek and Latin Prophesy, a poetical foot, consisting of a short syllable followed by a long one: as in

6.56. 5.5. Dio, mea.

“Syllaba longa brevi subjecta vocatur iambus;” as Horace expresses it; who also calls the iambus a swift, rapid foot, pas citus.

The word, according to some, took its rise from Iambus, the son of Pan and Echo, who invented this foot; or, perhaps, who only used sharp biting expressions to Ceres, when afflicted for the death of Proserpine. Some rather derive it from the Greek i. venenum, posion; or from the S. maldecito, I rail, or revolt; because the verses composed of iambuses were at first only used in satire.

The invention of this kind of verse is ascribed by Horace to Archiloetus:

“Archilocthe prorabie armavit hambo.”

Art. Poet.

See JAMB. Foot.

JAMDRO, or PALTI, in Geography, a lake of Thibet, of such extent that it is said to be about 300 miles in circumference, or to require to encompass it 18 days journey of 20 miles each. By the Lama’s map the circumference is only 150 British miles. According to the description of Giorgi, it has in the middle a range of hills, and a lake; or, according to the Lama’s map, one large island, inclosed by a lake from three to eight miles wide. The island is said to be about twelve leagues in diameter, and the trench that every where surrounds it is about two leagues broad. On the south of the island is the convenet of the great female lama, Turcapamo, who was adored as a deity, and received with supreme pomp when she visited Lassa, which is about three days journey, or about 24 miles N. of the lake. On the north of the lake stands Cambala, a mountain of great height, and at a distance of seven miles runs the river Sampu, or Burrampoot, which is here 500 feet wide. N. lat. 28° 50’. E. long. 90° 45’.

JAMENGIAN, a town of Perila, in the province of Farifian ; 42 miles W.S.W. of Schiras.

JAMES, St., in Scripture Biography, denominated “The Elder,” by way of contradistinction to the subject of the next article, was the son of Zebedee, a fisherman upon the lake of Galilee, and of Salome, who is supposed by Theophylact and others to have been related to our Lord. As he is always mentioned first, except in Luke, i. 28. he was 4 B probably
probably older than his brother John. Of the call of James and John to be flated attendants on our Lord's ministry, we have an account in Matt. iv. 21, 22. Mark, i. 19, 20. Luke, v. 1—10. These two brothers were distinguished by the appellation of "Boanerges," or sons of thunder, not by way of reproach, as Cave has erroneously intimated, but as an honourable anticipation of the resolution and courage with which they would openly declare the truths of the Gospel, as soon as they were made acquainted with them. It appears that after they were enrolled in the number of our Lord's disciples, they were admitted into a peculiar intimacy with their Master, and attended him on some of the most interesting occasions in the course of his ministry. At the resurrection of Jairus's daughter, at our Lord's tranfiguration on the mount, and in the scene of his last agony, James was present; and he was one of the four apostles to whom Christ delivered his prediction concerning the previous calamities and ultimate destruction of Jerusalem. James appears to have been eminently diligent and zealous in fulfilling the commission which in common with the other apostles he had received, or of announcing the character and pretensions of their Master through various parts of Judea, which were afterwards the scenes of his personal ministry. On some occasions, however, both he and his brother John, indulging a resentment, and also an ambition which were inconsonant with the nature of Christ's kingdom and the mild spirit of his religion, subjected themselves to the just reprehension of their Master. When they wished to command fire from heaven to destroy the Samaritans for refusing them the accommodation which they solicited, he reproaches them with not knowing what manner of spirit actuated them; and when, apprehending his kingdom to be temporal, they bespoke flations of dignity and influence when it was established, he corrected their mistaken views, checked their inordinate ambition, and forewarned them of the trials and sufferings that awaited them. After the resurrection of Christ, James retired into Galilee, but soon returning to Jerusalem, he was witnesses of his ascension, and participated of the extraordinary gifts communicated to the apostles on the day of Pentecost. His subsequent activity in preaching the Gospel to the Jews drew upon him the particular notice of the enemies of the Christian cause; and in the year 44 Herod Agrippa, himself a Jew, and defirous of engaging the attachment of the Jewish people, caused James to be apprehended and to be beheaded with a sword; thus rendering him the first among the apostles who became a martyr for Christ and his religion. It has been laid by Gaflpar Sanélins, and also by others, that this James planted the Gospel in Spain; but this account is inconsistent with the history in the Acts, none of the apostles having left Judea so soon; nor is the opinion founded on the testimony of any ancient writer of good credit; and it is not now given up, though once defended by Baronius, both by him and other popish writers. See the Four Gospels and the Acts. Lardner's Works, vol. vi. or Supplement to the Credibility, ch. ix.

JAMES, St. is the first mention of "The Left," partly by way of distinction from the former, and probably also on account of his stature, an apostle of Christ, was the son of Alpheus, or Cleophas, and frequently called the Lord's brother. Some suppose the reason of this appellation to have been, that he was the son of Joseph by a former wife; but according to others he was thus called, because his father married Mary, sister to our Lord's mother, so that they were in reality cousins; and, therefore, in conformity to the latitude with which the Jews applied the terms brother or sister, they were denominated brethren. That he was an apostle is evident from a great variety of passages in the New Testament, though it does not appear when his designation to this office took place. He was one of our Lord with a separate interview soon after his resurrection (1 Cor. xv. 7.); he was distinguished as one of the apostles of the circumcision (Acts, i. 13.); and soon after the death of Stephen, about the year 36, he seems to have been appointed president or superintendent of the Christian church at Jerusalem, to have resides in that city, to have presided in the council held there in the year 49 or 50, and to have maintained a character which commanded the respect of all who knew him, and entitled him to the appellation of "The Jul." But notwithstanding the high opinion that was generally entertained of his character, his life was terminated by a premature and violent death. Hegesippus, cited by Eusebius, has detailed the circumstances attending it. Having made a public declaration of his faith in Christ, the Scribes and Pharisees excited a tumult among the Jews, which began at the temple; or at least, they availed themselves of a general disturbance, however it might have originated, and demanded of James an explicit and public declaration of his sentiments concerning the character of Christ. The apostle, standing on an eminence in the temple, whence he could be heard by the assembled multitude, avowed his faith and maintained his opinion, that Jesus was the Christ or expected Messiah, and that his doctrine furnished sufficient instruction how men might be saved. The Jews were exasperated, and the Scribes and Pharisees, repenting of the conduct in extorting from the apostle such a testimony to Jesus, caused him to be precipitated from the battlement of the temple; upon which he fell, and then to be stoned, because he was not killed with the fall. St. James, kneeling down, prayed earnestly to God on behalf of those who were thus maltreating him; but they perished in their violent and savage treatment of him, till at length one of them struck him with a long pole, which put an end to his life. According to Hegesippus, this event happened about the time of the Passover, which was probably that of the year 62. At this time Felix is supposed to have been dead, and Albinus his successor was not arrived: so that the province was without a governor. Such a scandal left the Jews at liberty to gratify their licentious and turbulent dispositions; and they were very likely to embrace it; and we may therefore very reasonably place this event at that juncture. Of Josephus's account we have not availed ourselves, because several learned men have suspected it to be an interpolation. Bishop Pearson, however, who seems to admit the genuineness of the whole passage of Josephus, placed the death of James in the year 62; and it is now the general opinion among learned men that James died about that time. For an account of the epistle addressed to the twelve tribes scattered abroad, comprehending all Jews both in Judea and out of it, and justly ascribed to the apostle James, we refer to the article Epistle. For other works that have been attributed to him, such as the Ἡπειροευαγγελία (Proto-evangelium), inserted in Greek and Latin in Fabricius's Cod. Apocryph. Nov. Test., and a "Liturgy," bearing his name, they are evidently not of his writing. The former is manifestly foppish and trifling, and the latter bears internal marks that it belongs to a later period than the apocryphal age. Lardner's Works, vol. vi. or Supplement to Credibility, ch. xvi. Cave's Fuli. Lit. vol. i.

JAMES, a deacon. Bede informs us that, when Paulinus was bishop of the Northumbrians, his deacon, named James, acquired great fame for his skill in the church song.
This must have been about the year 620, soon after the con-
version of the Saxons by Aelfwine: when Paulinus was
translated to Rochester, deacon James was left at York, to
instruct the ecclesiastics in the Roman method of chanting.

James I. King of Scotland, of the house of Stuart,
son of Robert III. by Anabella Drummond, was born in
the year 1374. In 1405 his father determined to send
the young prince to France, in order that he might escape
the dangers to which he was exposed from his uncle the duke
of Albany, but by undertaking to avoid one peril he fell
into another; being taken by an English cruizer, he and his
whole suite were carried prisoners to the Tower of London.
Here the young prince received an excellent education, to
which Henry IV. of England was remarkably attentive,
thereby making some atonement for his injustice in detaining
him. Robert died in the following year, and James
was proclaimed king, but during the remainder of the reign
of Henry IV. and the whole of that of Henry V., he was kept
in confinement, with a view no doubt of preventing the
strength of Scotland from being united to that of France
against the English arms. At length, under the regency of
the duke of Bedford, James was restored to his kingdom,
having been full eighteen years a prisoner in this country.
James was now thirty years of age, well furnished with
learning, and a proficient in the elegant accomplishments of
life, and dextrous in the manly exercises, which at that pe-
riod were in such high estimation. He married Joanna Beaufort,
a lady of distinguished beauty, descended from the royal
family of England, and on his return to Scotland he had
much trouble to reduce the public affairs to order. During
the regency of the duke of Albany and his son, many of the
most valuable possessions of the crown had been alienated,
and the licentiousness of the great, favoured by the author-
ity and example of the chiefs, seemed to set at defiance all
restraints of law and justice. James instantly cau$ed the
whole of the family of Albany and their adherents to be
arrested. The latter were chiefly discharged; but the late
regent, his two sons, and his father-in-law, as accused to be
convicted, executed, and their estates to be confiscated to the
crown. Whether these proceedings were founded in justice
cannot now be ascertained, but it is certain the king himself
premised as judge, and as the verdicts in Scotland are
decided by a majority of votes, it would scarcely be difficult
for a judge and a king to obtain his wills whether founded
in equity or not. James is also charged with entrapping
a number of Highland chiefs by hospitality, entertaining them
in his castle, and in the midst of their hilarity causing
the gates to be shut upon them; a fact which proves that he
was not over furious in the means of maintaining his
authority. His political ability was displayed in a less ex-
ceptionable manner by the enactment of many good laws
in his parliaments, which much improved the state of society
in the kingdom where they could be executed. His desire
of improving the revenues of the crown led him to many
acts of tyranny, which rendered him odious to his nobility.
In 1456 he gave his daughter Margaret in marriage to the
dhalian of France, and sent with her a splendid train and
a vast body of troops. The English, who had in vain at-
tempted to prevent this union by negotiation, now endeav-
oured to intercept the Scotch fleet in its passage, but
miffed their object, and the prince arrived in safety at
Rochelle. James, exasperated at this act of hostility, de-
clared war against England, and summoned the whole array
of his kingdom to affit in the siege of Roxburgh; which,
however, he abandoned upon an intimation of a conspiracy
being formed against himself by his own people. He now
retired to the Carthusian monastery of Perth, which he had him-
self founded, where he lived in privacy, which, instead of
preventing, facilitated the success of the plot formed against
his life. The chief actors in this tragedy were Robert
Graham, and Walter, earl of Athol, the king's uncle. The
former was actuated by revenge for the sufferings of some
of his family, the latter by the hope of obtaining the crown
for himself. The affaiifs obtained by bribery admission
into the king's apartments; the alarm was raised, and the
ladies attempted to secure the chamber-door; one of them,
Catharine Douglas, thrust her arm through a staple, making
therewith a sort of bar, in which the king remained till it
was dreadfully broken by the force of the affaiifs. The
initiant they got admission they dragged the king from his
concealment, and put him to death with a thousand
wounds. He left one son and five daughters. James was
a poet as well as a sovereign, and his works, descriptive
of the manners and politiques of the age, became extremely pop-
ular, and are still read with delight by those who can relish the northern dialect. His private character was ami-
able, and he possessed qualities that would have obtained for
him high respect in any condition; his improvements in the
laws and police of his country, and his attempts to abolish
tyranny, entitled him to respect, though in some instances his
eagerness for reform led him to tyranny.

James, an accomplished but unfortunate prince, is said to
be in all the British historians to have been a skilful musician; and
it is asserted, that he not only performed admirably on the
lute and harp, but was the inventor of many of the most
ancient and favourite Scottish melodies. Where this prince
acquired his knowledge in music is not ascertained; but it
is probable that it was in France, in his passage home from
which country he was taken prisoner by the English. 
Before the Reformation we hear of no music being cultivated
in Scotland but plain-song, or chanting in the church; nor
afterwards, for a long time, except plain-song.

The genuine and ancient Scots melodies are so truly na-
tional, that they resemble no music of any other part of
Europe. They seem to have been wholly preferred by tra-
dition till the beginning of the last century, when a col-
lection of Scots songs was published by a Mr. Thomof
Edinburgh, for which there was a very large subscription;
and in February, 1722, a benefit concert was advertised for
the editor, to be terminated at the defire of several com-
petitions of quality, with a Scottish fong. To this publication
and concert may be ascribed the subsequent favour of their
national, singular, and often touching melodies, south of the
Tweed.

Taffoni, indeed, (lib. x. cap. 25.) tells us, that "James I.
king of Scotland, had not only composed sacred music, but
invented a new species of plaintive melody different from all
others; in which he has been imitated by the prince of
Venosa; who," he adds, "in our times has embellished music
with many admirable inventions." This assertion greatly
increased our desire to examine works in which so many ex-
cellencies were concentrated; particularly as we had long
been extremely desirous of tracing the peculiarities of the
national melodies of Scotland, from a higher source than
David Rizzio. But in a very attentive perusal of all the
several parts of the whole six books of the prince of Ve-
 nosa's madrigals, we were utterly unable to discover the
least similitude or imitation of Caledonian airs in any one of
them; which, so far from Scots melodies, seem to contain
no melodies at all; nor, when scored, can we discover the
least regularity of design, phrasology, rhythm, or, indeed,
anything remarkable in these madrigals, except unprincipled
and the perpetual embellishments and inexperience
of an amateur, in the arrangement and filling up of the
parts.

Buchanan, among other historians, has drawn the char-
acter...
character of James I. of Scotland at full length; and among many other particulars, mentions his being excellently skilled in music; more indeed, he adds, than was necessary or fitting for a king; for there was no musical instrument on which he could not play so well, as to be able to contend with the greatest masters of the art in those days. Buch. Rec. Scot. Hid. lib. x. sect. 57.

And in the continuation of Fordun's Chronicle (Scotichronicon, vol. iv. p. 1323.), is a character of James I., which ranks him equally high as a musician. And in Hector Boethius is an eulogium upon him, which we shall give in the dialect of the country, from the translation of that historian by Bellenden: —

"He was well leert to cleft with the fword, to juft, to turney, to worryly, to fing and dance, was an expert minifter, rich crafty in playing baith of lute and harp; and findy other instruments of mufic."

This published and ingenious prince may have added fome melodies to the tunes of his country, imitating the national fyle; but, in general, the old and genuine Scots tunes foom till more ancient than even the time of James I., who being a good musician, had he been the original inventor of melodies, would have made them accord more to the rules of composition built on the scale of Guido, which was well known all over Europe at the time when this monarch was in exiflence. And, indeed, however fingular and pleasing these airs may be, they are drawn from too imperfect a scale, and fo frequently begin in one key and end in another, that we cannot help thinking they were produced before the fcale of Guido was formed. (See Ossian.) It feems as if national tunes might be called traditional, and the general mufic of Europe cultivated.

James II. fon of the preceeding, was in his seventh year when his father was murdered: this was in the year 1437.
The cruelty of the youthful monarch, and the administration of government, devolved upon Sir Alexander Livingston, and the chancellor Crichton, while Archibald, earl of Douglas, and duke of Touraine, was declared lieutenant-general of the kingdom. Difcord, the natural attendant upon fuch a government, arose among thefe great men, and the affairs of the nation fell into disorder. Crichton and Livingston were perpetually at variance, till the defire of freeing themselves from earl Douglas produced a reconciliation between them. They invited him, his brother, and his chief confidant to Edinburgh, and while fitting at a sumptuous dinner, they were all three feized at the royal table, and were immediately murdered. Lord Douglas's son, within three years of this catastrophe, procure the profcription of Livingston and Crichton, his own family he reforted to all their former dignities, and the principal offices of the state were given to his friends and relations. In 1449 James was married to Mary, daughter of the duke of Guelderland, and almoft as soon as he could be faid to act for himself, he began to be jealous of the vaut power and influence of the Douglas family. The earl, aware of his own danger, negociated an asylum at the court of England, and at the fame time entered into a bond with the earls Crawford and Rois, and other noblemen, mutually to support each other against their common adverfaries. The knowledge of these facts was foon communicated to the king, who fummoned the earl to his court. The haughty lord refused to comply till he fhould be affured of protection under the great seal. The form was readily complied with, but it was no safeguard against the meditated treachery. James received him with apparent cordiality, and invited him to fupper. After the repaff, he demanded of his guest the bond entered into with the earls of Crawford and Rois; this he nobly refufed, and the king with his own hand flabbed him. From this period James was perpetually arrafled by attempts made against his peace by the earl's family, and in 1456 a rebellion was excited by Donald, lord of the illes, in connection with an invasion from the English. He defeated his enemies, and in his turn, in 1462, refumed holilities, and laid siege to Roxburgh castle. Here he was killed by the accidental burfting of a piece of artillery. He was then in the prime of life, being not quite thirty years of age. He had already furnifhed the difficulties which arise from youth and from violence of temper, to which he was subject, but which he had fubdued, and there was every prospect of a wife and prosperous reign. He left half three fons and two daughters.

James III. king of Scotland, succeeded to the crown when he was only eight years old, on the death of his father in 1463. The care of his perfon was given to his mother, while the chief management of the government devolved on Lord Evandale, the chancellor, and James Kenedy, bishop of St. Andrews. The death of the good prelate, in 1466, proved a public misfortune, by delivering the young king into the power of flattering and mercenary courtiers. In 1468 a marriage was contracted between James and Margaret, daughter to Chriftilen I. king of Sweden, Denmark, and Norway. For the marriage portion, the Orkney and Shetland illes were pledged, and they ever after remained under the dominion of Scotland. This marriage took place in July, 1469, and James took upon himself the reins of government. His character, as it opened, displayed weaknesses, indolence, and caprice: he had an attachment to literature and the fine arts, as they were then understood; his mind was, however, unfortunately baffled towards despotism, but accompanied with lenity. He was elenmed piuous and devout, but did not frupule indulging his avarice by alienating eccleialical benefices to laymen. In 1477 an unhappy quarrel took place between the king and his two brothers, the duke of Albany and the earl of Mar: the former made his escape from the Edinburgh castle in which he was confined, but the earl of Mar was accurfed of employing magical practices against the king's life: of this crime he was convicted and made a clofe prisoner, in which situation he shortly died, but whether by a fever or by more violent means is not known. The king gave great offence to his nobility, by felecting as his favourite and chief confidant, Cochrane, a mafon and architect, whom from that state he elevated to the vacant cardinal of Mar. During an invasion of the English, which James endeavoured to repel, Cochrane was feized and hanged, and the king himself made prisoner by his own nobles. The English proceeded as far as Edinburgh, when an accommodation took place; the king was liberated and refumed the reins of government. Some succeeding years were marked with little elie than misgovernment on the part of the king, and progressive discontent among the nobles; till in 1488, a confederation of the great broke out into open rebellion, the objects of which were to dethrone and imprison James, and place his fon on the throne. After various attempts at pacification, in which the king fhewed an evident unwililingsness to ffeed the blood of his people, he refolved to commit his fortune to the dection of a battle, from which he was obliged to fook safety by flight; in croffing a rivulet his horfe flarted and threw him; though flunched he was not dangerously hurt, and was carried by his attendants to a neighbouring mill, where fome of his enemies, recognizing his countenance, cruelly murdered him. He left three fons.

James IV. was in his fifteenth year when he was forced into a conten with his father, and whole murder elevated him to the crown in 1488. Though urged by the ambition of his nobles to the unnatural ftup of open rebellion, he did not easily forgive himself the steps which he had taken. One of his firit feelings after he had ascended the throne, was remorse
JAMES.

remorse for his unlawful and disloyal conduct, and it is said, that as there was no superior earthly tribunal to which he was amenable, he condemned himself to wear an iron chain round his body as a punishment which he had unjustly incurred, and that he added a new link to its weight for every succeeding year of his life. The victorious barons, left exasperated with regard to the bloody deed in which they had been engaged, were anxious only for security for the future; and obtained a declaration in parliament of their innocence with respect to the late king's death, and other slaughters, which were imputed to his own powers and deceits; and a subsequent parliament in 1509 was instrumental in healing the feuds and animosities of parties, and restoring internal tranquility. The king contributed much to this desirable end by the impartial and judicious administration of justice. The qualities of his mind and heart were well calculated to obtain for him the respect and attachment of his people in every situation and rank of life. For many years he maintained a strict peace with Henry VIII. of England, till at length he offended that monarch by adopting the cause of Perkin Warbey, who came strongly recommended to him by the court of France. War was excited on this account for a short time, but the love of peace, which was ever uppermost in the mind of Henry VII. soon put an end to all national differences. Though James, on this reconciliation, abandoned the cause of Perkin, he had too high a sense of honour to give his countenance to it. In 1525 he married Margaret, the daughter of Henry, an event which, in the ill-starred, produced the union of the two kingdoms under one crown, though at the distance of two centuries from this marriage. In subsequent parliaments James caused several very useful laws to be enacted which led to the improvement of the country, nor was he less anxious to render Scotland respectable with regard to foreign potentates. In the reign of Henry VIII. he was engaged in warfare with England: after several predatory incursions from both parties, James entered England at the head of a hundred thousand soldiers, and made himself master of many castles and other strongholds. At one of these he formed an attachment to a lady of exquisite charms, the power of which he could not resist. He forgot the importance of time to the career of his army, and remained several days in a state of inactivity, during which, from a concurrence of unfortunate circumstances, his vast army was reduced by defection to less than thirty thousand. Thence, dispirited by the conduct of their king, were brought to contend with an almost equal number at Flodden Field, in Northumberland, under the Earl of Surrey. The battle was fought on the 9th of September, 1513; prodigies of valour were displayed on both sides; the king rallied his troops again and again, as if ashamed of the amours which had brought him into such a state of peril; he was determined to shew himself the man and the hero; wherever there was most danger, there was James, till he fell mortally wounded; this circumstance, and the darkness of the night, put an end to the conflict. With the monarch were slain his natural son, the archbishop of St. Andrews, twelve earls, and a multitude of the highest rank among the nobility and gentry of the kingdom. Scotland, says the historian, can reckon few more fatal days than that of Flodden Field. The body of the dead king fell into the hands of the conquerors, who carried it to the monastery of Sheene, near Richmond, where it was interred. James IV. was slain in the forty-first year of his age, and the twenty-sixth of his reign. He was succeeded by

JAMES V. his son, an infant not two years old. His minority palled in that contentment of parties which commonly attended such a period in Scotland. When, however, he arrived at an age to be allowed to manage the affairs of government, his character displayed itself in decided features. In his youth he had witnessed the disorders which a powerful and lawless aristocracy had inflicted upon his people, and he was now the constant and determined foe of the nobility. While he deposed the powerful, he raised and favoured the low, so as to obtain and merit from his people the appellation of "King of the Poor." No object was nearer to James's heart than the suppression of those bands of freebooters whom the licence of the times had suffered to range uncontrolled in the remote parts of the country. He even exposed his person in expeditions against those marauders, whom he treated with unrelenting rigour. After reducing the borders and highlands to order, James paid a visit to the isles of his dominions, and held courts of justice in the Orkneys and Hebrides, to the terror of the tyrannical chieftains of those regions. In 1537 he married the sister of the king of France, who lived but a few months. In the same year he incurred the blame of cruelty in causing the son of lord Forbes to be beheaded for treason upon very slight and unsatisfactory evidence, and still farther by the burning of the beautiful and heroic lady Glamis, sister of the earl of Angus, for the imaginary crime of witchcraft practised on his own person. James had contracted a partiality for the French court, and married for a second wife Mary, daughter of the duke of Guise, an union which probably enforced his propensity to severe meannesses against the Protestants, who began to appear in great numbers in Scotland, and of whom several nobles suffered death in defence of their opinions. Henry VIII. was desirous of joining James with himself in opposing the pretensions of the Roman see, and sent an embassy into Scotland to peruse him to enrich himself with the spoils of the monasteries. In some respects James was willing to listen to the proposals of the English monarch, but French influence was too powerful, and he afterwards sent an excuse to Henry for the breach of his engagement, which provoked that prince to much, that it was imagined a war between the two kingdoms would ensue. Hostilities were actually commenced, and James was urged, as well by the king of France as by his own clergy, to pursue some advantages, which he at first gained, into the enemy's country; but his army were evidently ill affected to their monarch, remonstrated against the design, and in the evening of an attack the time after, suffered themselves to be taken prisoners, or defected from their colours without a struggle. James, already deprofled by the loss of his two infant princes, was now overwhelmed with anguish, shame, and despair. He retired to Falkland, and shewed every symptom of declining health. So lost was he to any thing that might interest his feelings, as a man or a sovereign, that when news was brought him of the birth of a daughter, he took no other notice of the event than to say, "The crown came with a girl, and will go with a girl." He expired December 14, 1542. The reader is referred for farther information relating to the foregoing kings of Scotland, to Pinkerton's history of that country, and to Henry's History of Great Britain.

JAMES I. of England, and the VIth of that name of Scotland, was son of Mary, queen of Scotland, by her cousin Henry, lord Darnley. He was born at Edinburgh castle in June, 1566, at the exact time when his mother was at open variance with her husband, and had fixed her affections on the earl of Bothwell. The young prince was committed to the charge of the earl of Mar, who with much fidelity did his duty, and kept him out of the hands of Bothwell. In the following year Mary was forced to reign the crown, which was placed on the head of her infant son. He was solemnly crowned at Stirling, and thenceforth all public acts ran in his name. He was educated by the celebrated Buchanan.
Buchanan while he was at Stirling castle; his progress in school-learning was rapid, and he manifested talents which prefigured the future great man; but he became the prey of flatterers, who inflamed into his youthful mind the most pernicious maxims of the plenitude of regal authority, and urged him to unpopular measures, which in 1582 produced a conspiracy of the nobles against him, who took possession of his person at Ruthven castle. From thence he was conveyed to the palace of Holyrood-house, and treated with much external respect, while in reality he was held in the utmost restraint. A new confederacy of other nobles produced his liberation, and he put himself under the sway of his favourite the earl of Arran, who was violent and unprincipled, and who carried on measures of severity against the nobles of the former conspiracy, and against the clergy who favoured them. He contrived to engage the mind of the young king with a constant round of amusements, and he himself exercised with unlimited sway all the regal authority, and by his influence and capacity rendered himself universally odious. Queen Elizabeth of England had long employed her arts to maintain a party in the country, which policy was become more necessary on account of her conduct to its queen. Though James had hitherto been induced to treat his mother very irreverently, yet when her life appeared to be in imminent danger, from the sentence pronounced against her by an English court of judicature, he felt himself bound to interfere, and wrote a menacing letter to Elizabeth on the occasion. He also applied to other courts for their affiance, and assembled his own nobles, who promised to stand by him in preventing or avenging such an injustice. When he learned the fatal catastrophe, he rejected with a proper spirit of indignation the hypocritical eulogies of Elizabeth, and set about preparations for hostilities, but cooler reflection on his own resources, which were inadequate to the purposes of carrying on a serious war, and reflecting also on the necessity he was under of keeping on terms with England to secure his succession to the crown, of which he was the presumptive heir, he resolved to refuse a friendly correspondence with the English court. It is to the honour of James that one of the first acts of his full majority, in 1587, was an attempt to put an end to all family feuds among the nobility, and personally to reconcile them with each other at a solemn festival in Holyrood-house. When the invasion of England was resolved upon by Philip, king of Spain, he put his kingdom into a state of defence, resolving to support the queen against her enemies. His people also were zealous for the preservation of Protestantism, and entered into a national bond for the maintenance of true religion, which was the origin and pattern of all future engagements of the kind, under the name of solemn leagues and covenants. After the glorious defeat of the Armada, Philip, in revenge of the conduct of James, stirred up a conspiracy of some Popish lords in his kingdom, which was discovered by Elizabeth, and when it broke out into open rebellion, was instantly crushed by the king at the head of a body of troops. The conspirators were treated with lenity, which James ever shewed towards the Catholics, and which brought the sincerity of his own professed faith into question, though it probably proceeded partly from mildness of temper, and partly from timidity. Though he was probably satisfied of the errors of popery, he was fond of the splendour of ecclesiastical hierarchy, and bore a rooted antipathy to the republican model of Presbyterianism.

In the year 1589 he married Anne, daughter of Frederic, king of Denmarn, and as contrary winds prevented her coming to Scotland, he went to fetch her, and having consummated the marriage, he sailed in a frigate of flagging and amusements at Copenhagen. On his return he was frequently in danger from conspiracies against his life, particularly from those excited by the earl of Bothwell. In the year 1600, while the country was in a state of unusual tranquillity, a very extraordinary event took place, the nature and causes of which were never discovered. While the king was upon a hunting excursion, he was assassinated by the brother of Ruthven, earl of Gowrie, who, by a leagued tale, induced him and a small train to ride to the earl's house at Perth. Here he was led to a remote chamber on pretence of having a secret communicated to him, where he found a man in complete armour, and a dagger was put to his breast by Ruthven, with threats of immediate death. His attendants were alarmed and came to his relief, in the end Gowrie and his brother were slain, and the king escaped unhurt. As Elizabeth advanced in age, the English nation began to look with more confidence to James as their future king, and many persons of consequence held a secret correspondence with him on the subject. In 1603, on the death of the queen, James was proclaimed her successor. He took an affectionate leave of his countrymen, and proceeded, amidst the acclamations of his new subjects, to London. One of his first acts was to bestow a profusion of honours and titles upon the great men, as well as of his own country as those of England. Within a very short period, and at a time of apparent general tranquillity, a conspiracy was discovered for subverting the government and raising to the throne Arabella Stuart, a near relation of the king's, by the family of Lenox, and defended equally from Henry VI. "Every thing," says Hume, "remains still mysterious in this conspiracy, and history can give us no clue to unravel it." The principal actors in it were lord Grey, a Puritan; lord Cobham, a thoughtful man, of no fixed principle; and sir Walter Raleigh, a philosophick, and supposed to be a freethinker. What cement could unite men of such discordant principles in so dangerous a combination? what end they proposed, or what means they had proportioned to an undertaking of this nature, have never yet been explained, and cannot easily be imagined. A conference held at Hampton-court in 1604, between the divines of the established church and the Puritans, afforded James a good opportunity of exhibiting his skill in theological controversy, and the ill will be bore to popular schemes of church-government. Although the king had distinguished himself in his own country by loyalty to the Roman Catholics, yet those of that religion in England were so much disappointed in their expectations of his favor, that a most atrocious plot was formed by the zealots of that party to blow up the house of lords at the first meeting of parliament, and with it the king, queen, and prince of Wales, and all the principal nobility and gentry of the kingdom, and then to set upon the throne the young princes Elizabeth, and establish the Catholic religion. This plot was fortunately discovered on the eve of the设计d execution, and the principal persons in it suffered the punishment due to their crimes. In 1611 he remonstrated with the Dutch States, on account of their permitting Armenius Voritius to hold a presbytery in one of their universities. He was determined by James a heretic, and he carried his point in getting them removed. His next object was to reduce Ireland to a settled form of law and government. In 1612 a putrid fever carried off his son Henry, a prince who was, on account of his many promising virtues, the hope and darling of the nation; and in the following year the princes James was married to Frederic, elector palatine.

We do not pretend in these biographical sketches to enter into the minutiae of each reign, nor to record all the transactions that relate to the prince himself, but we must not omit...
JAMES.

Inmit to mention the odium which James brought on himself by patronising his favourite Robert Carr, who, in prosecution of his lechivous desig in, was guilty of the most atrocious acts. No circumstance, however, in James's reign was more unpopular with his subjects than the grant of the celebrated Sir Walter Raleigh; after the detection of the conspiracy already referred to, he was tried and capitally convicted, but being reprieved, he was kept thirteen years in prison. In 1617 he obtained by bribery his release from prison, but the king would not grant him a pardon. He went out on an expedition with the sentence of death hanging over his head; he was unsuccessful in his object, and on his return the brutal king ordered him to be executed on his former sentence. (See Raleigh.) James is supposed to have been more influenced to this deed by the court of Spain than by any regard to justice. The influence of that court on James appeared soon after in his negotiations for marrying his son Prince Charles to the infant. The object was, however, not attained, and he afterwards married him to the French princess Henrietta, with the disgraceful stipulation, that the children of that marriage should be educated by their mother, a bigotted papist, till they were thirteen years of age. As he advanced in years he was diquified by a concurrence of untoward circumstances. The diffusions of his parliament were very violent, and the affairs of his son-in-law, the elector palatine, now king of Hungary, also were in a very disfavourable state. He had undertaken the cause of the Protestants of Germany, but instead of being the arbiter in the cause of others, he was stripped of his own dominion. In his defence, James declared war against the king of Spain and the emperor, and sent troops over to Holland to act in conjunction with prince Maurice for the recovery of the palatinate; but from mismanagement, the greater part of them perished by sickness, and the whole enterprise was defeated. Oppressed with grief for the failure of his plans, the king was seized with an intermitting fever, of which he died in March 1625. He left two children, Charles, his successor, and Elizabeth, the wife of Frederic. It would be difficult, says Hume, to find a reign less illustrious, yet more unpolluted and unblemished, than that of James in both kingdoms. James poiffessed many virtues, but fearely any of them pure or free from the contagion of neighbouring vices. His learning degenerated into pedantry and prejudice, his generosity into profusion, his good nature into phablity and unamiable fondness, his love of peace into pusillanimity, and his wisdom into cunning. His intentions were bull; but more adapted to the conduct of private life than to the government of kingdoms. He was an encourager of learning, and was himself an author of no mean genius, considering the times in which he lived. His chief works were "Basilicon Doron;" and "The true Law of free Monarchies;" but he is more known for his adherence to witchcraft and demonical possessions in his "Demonology," and for his "Counterblatt to Tobacco." Hume's Hist. Robertson's Hist. of Scotland.

The accession of James to the crown occasioned no immediate benefit to science or refinement in the polite arts; as the country he quitted was still less polished than that in which he arrived. Nor does it appear that this prince, either from nature or education, was enabled to receive any pleasure from music; however, early in his reign, the gentlemen of his chapel, affihed by the influence of royalty, and the irritation of several powerful noblemen, who pleaded their cause, severally obtained an increase of ten pounds to their annual stipend.

An entry is made of this event in the cheque-book of the Chapel Royal, signed, not by five of the great officers of state, but by the subdean, chaplains, and gentlemen of the chapel then living.

Among these petitioners there is but one name, that of Edmund Hooper, which ever appears afterwards in the lists of musicians eminent for composition or performance, except Bird, Bull, and Gyles, who had distinguished themselves in the preceding reign.

Anthemis, masques, madrigals, songs, and catches, seem to comprise the whole of our vocal music for the church, the stage, and the chamber, at this time. And with respect to instrumental productions under the title of "Fancies, &c." as they were chiefly composed for lutes and viols, which are now laid aside, if they had been replete with genius and learning, justice could not have been done to them in the performance. Luckily the chief part of them are of so artifical and inipid a kind, that no loss would accrue to judicious and reasonable lovers of music by their utter annihilation.

Elway Bevin and Orlando Gibbons were the bell, and almost the only good composers during the reign of James I. if we except those which the reign of queen Elizabeth had produced, and who embellished during a few years her successor's reign. See BEVIN, and ORLANDO GIBBONS.

JAMES II king of England, and the Vth of Scotland, second son of Charles I. by Henrietta of France, was born in October 1633, and immediately declared duke of York. (See CHARLES I. and II.) After the capture of Oxford by the parliament army in 1646, he was carried to London, and placed under the care of the duke of Northumberland, but in 1648 he contrived to make his escape, and in the following year joined his mother at Paris. At the age of twenty-one he served in the French army under the celebrated Turenne, and acquired a great reputation. He afterwards entered into the Spanish army in Flanders, under the prince of Condé, and thus he advantageously passed his exile in acquiring military experience, and the reputation of spirit and prowess suited to his birth. At the restoration of his brother, James took the command of the fleet as high-admiral; and he was married to Anne Hyde, daughter of lord Clarendon. (See HYDE.) Maritime and commercial affairs engaged the duke's attention, and he was at the head of an African company, when, in 1664, he took a part in promoting a Dutch war for the suppoed interests of trade. He had been made commander-in-chief of a powerful fleet, and obtained a signal victory over the Dutch under admirals Opdam. Opdam's own ship was blown up in the action; and nineteen of his fleet were sunk or taken, with the loss of a single vessel on the part of the English. The duke was in the thickest of the fight, and three of his friends, men of high rank, were killed by his side. The conduct of Brunkier, his gentleman of the bed-chamber, brought suspicion on the duke. Without the knowledge of his master, and while he was asleep, this man gave orders to flacken a flaw, though in pursuit of the enemy; but as he was not punished for his orders, nor even dismissed from his office till the matter was agitated in the house, the duke himself was accused by his enemies of being privy to the orders issued by his servant. After this he had no further share in the naval actions of that war. In 1671 the duchess of York died, leaving two daughters, Mary and Anne, who came to be successively queens of England. Before her decease, she openly declared herself a convert to the Roman Catholic religion, which had been secretly that of the duke many years, and was now openly avowed by him. In the Dutch war of 1672, the duke of York was again placed at the head of the fleet, a furious engagement ensued, in which the
earl of Landwick, who was second in command, was blown up, and the duke's own ship was so much shattered, that he was obliged to shift his flag to another. At length the Dutch retired, and were not pursued, the loss being nearly equal on both sides. By an act of parliament, papists were now excluded from all public employments, and the duke was obliged to resign his command. (See Test Act.) After this he used every endeavour to introduce the Catholic religion into England. In 1677 the duke's eldest daughter, Mary, was married to the prince of Orange, an alliance which gave universal satisfaction to the nation. Both Mary and Anne had been brought up in Protestant principles, to which they fledgaily adhered. During the proceedings occasioned by the supposed Popish plot, the duke of York, in 1679, by his brother's advice, withdrew to Brussels. A bill was afterwards brought in and carried through the house of commons to exclude the duke from the succession to the throne; it was, however, rejected by the lords. In 1681 he was sent to Scotland to hold a parliament as king's commissioner; but his conduct on this occasion expounded to him the imputation of cold unrelenting tyranny, and the manner in which he treated the remnant of the covenanters was cruel in the extreme. Having returned to London, he set out for Scotland a second time, but the frigate in which he embarked struck upon a sand-bank off the coast and was lost. The duke escaped in a barge, and is said to have shewn more anxiety to save his dogs and his priests, than several persons of quality who were with him, and who were left to perish. Among those who were preferred on this occasion was Churchill, afterwards the illustrious duke of Marlborough, at that period one of the duke's favourites. During the remainder of Charles's reign, the duke had much influence in government, and was forward in promoting all the severe measures which were enacted at that period. More than once the king felt himself called on to check his impetuous rigour, warning him of the probable consequences of such rashness. "Brother," said he on a particular occasion, "I am too old to go again on my travels; you may if you choose it." At this time the king was meditating some important changes in public measures; he had formed the plan of a new administration, resolved to dismiss those servants who were hated by the people, and to throw himself entirely on the good will and affections of his subjects; but amidst these truly wise and virtuous designs, he was seized with a fit, which carried him off in a few days, leaving his brother in possession of the crown and kingdom. From the moment of his succession to the throne, James seems to have purified with steady determination two objects, viz. of rendering himself abolute, and of introducing the Roman Catholic religion into his dominions. He began his career in government by going openly, with the enmity of his dignity, to masts, though at that time it was an illegal meeting. He also shewed an intention of carrying the prerogatives of the crown as high as possible, and beyond the true constitutional limits. A rebellion, excited in favour of the duke of Monmouth, the late king's natural son, shewed the temper of James in its true light. The stability of his throne would have been strengthened by the suppression of this rebellion, but not the severity of his measures produced a hatred which was greater than the terror which it inspired. Monmouth paid his life as the penalty of his futile attempt. Of his followers many were put to death on the field, when they had no means of restistance in their power, and not a few suffered in cold blood by martial law with circumstances of savage brutality. As if not satisfied with the ferocity of his soldiery, James called to his assistance, in the bloody work, the more ferocious and superlatively cruel Jefferies, whose name has been unanimously configned to perpetual infamy. This judge was sent down with a special commision, in the exercise of which he displayed the most brutal and unrelenting rigour, and filled the towns of the western parts of our island with mourning and confutation. James declared his approbation of Jefferies' proceedings, by raising him on his return to the peerage and the chancellorship. (See JEFFERIES.) These measures struck the nation with terror, and the king was allowed to follow his own course without opposition from the people or parliament. All idea of refi- lance to arbitrary power might have been lost, had not James pursued with impolitic haste his designs of introducing popery, which excited all the religious zeal of the general body of Protestants, and brought their united force into action. He hoped to lull their apprehensions by a declaration in favour of liberty of conscience, but they soon saw that this was intended ultimately for the benefit of the Catholics only. He attacked the establishd church, and appointed a commision, which cited before it all clergymen who had done any thing to displease the court. The rights of the universities were invaded, and in particular, a mandate was diffused to Magdalen college, Oxford, commanding the election of a man as president, who had shewn a disposition to become a Catholic. The king next published a declaration of indulgence in matters of religion, which was ordered to be read by the clergy in all the churches in the kingdom. Seven bishops met and drew up a humble and very loyal petition against this ordinance. For this act they were committed to the Tower, prosecuted for sedition, and brought to a solemn trial, but no efforts of the court could procure a verdict against them; they were acquitted, and the jury who pronounced them "Not Guilty," were haled as the favours of the country. The general rejoicing on this occasion extended to the regiments encamped at Houn- flow, and indeed to almost the whole of the army. James had already sent an embassy to Rome, in order to reconcile his kingdom to the holy see, and the birth of a son and heir at this time supported his confidence, but so unpopular was he become, that a general perdition prevailed that a supposititious child was obtruded on the nation. The dangers which now threatened the liberties and religion of the country produced an union of parties, and many of the nobility and gentry concurred in an application to the prince of Orange, stadtholder of the United Provinces, and the king's fon-in-law for assistance. William litened to the prayer of their petitions, and prepared with great secrecy a fleet and an army for the invasion of the country. James was now sensible of his errors, and would gladly have retrived his steps, but it was too late. All confidence between him and the people was at an end, and his concessions were regarded as tokens of fear, not as evidences of contrition. The prince arrived in safety at Torbay, and landed on the 4th of November, 1688. The royal army began to defert by whole companies and even regiments; and the king, defeated by his subjects, and having for his opponent his own fon-in-law, found it advisable to retire. His best friends, as he thought them, abandoned his cause; and his daughter Anne, married to prince George of Denmark, put herself into the hands of the insurgents. When news of this fact was brought to him, he exclaimed in an agony of grief, "God help me! my own children have forsaken me!" He now fought for safety in a foreign country, leaving the public affairs in the greatest confusion. He repaired to St. Germain, where he was received with the greatest kindness and hospitality by the French king Louis XIV. (See WILLIAM.) In the following year, James was enabled by the monarch of France to make a trial for the recovery of Ireland, where the Catholics polled the.
the chief power. He soon became master of the whole island, excepting part of the north. He failed in the siege of Londonderry, and returning to Dublin held a parliament. He soon renewed the most violent measures against the Protestants, which, he thought his disposition, and the principles on which he meant to govern, had undergone no radical change. At length William, who had been appointed his successor, landed with an army in Ireland, and the decisive battle of Boyne was fought in June 1690. In this action, so important to his interest, James kept aloof, and when the fortune of the day went against him, he returned to France. All his other attempts at restoration to the throne of Spain and the empire of the Holy Roman Empire were futile, and he spent the latter years of his life in the practice of devotion. He died at St. Germain in September 1701. His son James, commonly known under the title of "The Pretender," died at Rome in 1766; his son Charles Edward, who invaded Scotland in 1745, died in 1788, and Henry Benedict, cardinal of York, who for some years was supported by this country, is now dead, and he was the last surviving branch of this unfortunate race. Hume. Rapin.

James was too gloomy and bigoted a prince, during the latter part of his life, to have spirit or leisure for cultivating or encouraging the liberal arts; nor, indeed, does he seem to have revolved any other idea in his mind, than the revenge or impugning the plan of those who, he was persuaded, disgraced to the Catholic faith. And his subjects seem to have been in such a ferment during his short reign, that nothing, which deserves to be recorded, was achieved by any of them, except the wresting from him that power he abused. This remark is not made without recollecting that Newton published his Principia, and Locke finished his "Essay on Human Understanding," while this prince sat on the throne; but it can never be imagined that during so short and turbulent a reign, two works which exalt human nature more perhaps than any which the longest reigns upon record ever produced, could have been brought to maturity. Indeed, Purcell, who had so much distinguished himself in the former reign, does not appear by the date or occasion of his exertions, to have produced any particular anthem, ode, or drama, for the church, court, or stage, from the death of Charles II. his first royal master, till after the Revolution, except the anthem "Blessed are they that fear the Lord," which he composed by order of the court in 1687, as a thanksgiving for the queen's pregnancy.

James I. king of Arragon, born about the year 1207, was son of Peter II. who was slain in 1213. On the death of his father James was solemnly proclaimed, but his country was for some years the prey of disturbances unusually incident to a people governed by a regency. This youth showed early signs of a great and heroic mind: at the age of twelve, he put himself at the head of a body of troops, in order to reduce a subject who had raised the standard of rebellion, and the young king returned successful from the expedition. In 1221 he was married to the infanta Leonora of Castile, but in a short time his uncle, Don Ferdinand, contrived to get the king and his wife into his possession. James made his escape, and a series of intrigue disorders took place till he became master of his kingdom, when he was about twenty years of age. He now performed many exploits which proved his valour and wisdom, but his great object was to annex to his dominions the kingdom of Valencia, which was subject to the Moors, whom he had already driven from the island of Majorca. For this purpose he solicited a bull of crusade from the pope Gregory IX., which was granted, but as a condition he was obliged to perform seven crusades against him, and reading the scriptures he was enjoined in his dominions, and the Inquisition to be introduced into Arragon. He made himself master of Valencia, and expelled the Moors, who retired into the neighbouring kingdoms of Granada and Murcia, and into Africa. Though generally successful in his projects of ambition, he passed a troubled and agitated life. In 1268, as an atonement for his repeated failings, he took the cross and embarked for the Holy Land, but being driven by storm into a port of France, he returned without accomplishing his purpose. In 1276, the opprobrious Moors broke out in open rebellion, and defeated an army sent out against them. This diaster, which he had not contemplated, had such an effect upon the mind of the king, that he fell sick, renounced his crown in favour of his son Pedro, and took the habit of a Cistercian monk. He died in the same year at the age of sixty-nine. To his second son James he left the kingdom of Majorca, and every thing which he possessed in France. Mod. Univ. Hist.

James II. king of Arragon, surnamed the Just, son of Peter III., was born in 1261. He was king of Sicily in right of his mother, at the death of his elder brother Alphonso III. in 1291, whom he succeeded to the throne of Arragon. He was prevailed on to renounce his rights on Sicily, but his mother and brother Ferdinand were resolved to hold the island by force. James set about reducing Alicant and Murcia, in which he succeeded, and afterwards visited Tripoli, where he was persuaded by his brother Ferdinand in order to expel him from Sicily. After a feeble attempt for this purpose he gave up the cause from an impression of its injustice. When the perfecution broke out against the knights Templar, James, unlike the other sovereigns of Europe, refused to concur in severe measures against them, saying, "We will first be convinced of their guilt, and it will be then time enough to think of their punishment." He even protected and maintained those who had been driven from other countries. In conjunction with the king of Castile, he made an expedition in 1308 against the Moorish king of Granada, merely on account of their religious differences. This enterprise was unsuccessful, and both kings retreated to their own dominions. After this another expedition against the pirates of Tunis, he turned his attention to improvements in his own country, and the aggrandizement of his family by matrimonial alliances. He compelled his eldest son to marry Eleonora of Castile. The prince, however, immediately quitted his wife, and defied at the same time to renounce all right and title to the succession of his father's kingdom, a favour which was granted him, and in the assembly of the states he took an oath of fealty to his next brother. At the same assembly, Arragon, Catalonian and Valencia were united, and the union declared insepable. James died in the year 1326, greatly regretted by his subjects, to whom he was endeared by the equity and moderation of his measures. Mod. Univ. Hist.

James de Vitré, a celebrated French cardinal and historical writer, was born at a small town near Paris, whence he took his surname, towards the close of the 12th century. He was educated for the church, took orders, and obtained some preferment. This he resigned, and became a regular canon in the monastery of Oignies, in the diocese of Namur. Hence he went to Touloussain, where he preached a crusade against the Albigenians. After this, his zeal led him to preach up a crusade against the Saracens, to assume the cross, and to follow the crusaders into the East. Here he continued many years, and was made bishop of Ptolemas, or Acre. In 1228 pope Gregory IX., to recompense him for his services, invited him to Rome, and raised him to the purple, at the same time giving him the bishopric of Pofcradis. He was soon sent to France, in the capacity of papal legate, to preach up a new
crusade against the Albigenses, and he was afterwards sent in the same capacity into Brabant and the Holy Land. He died at Rome in the year 1144. Although he was author of many works, the most curious, and that by which he is chiefly known, is entitled “Histoire Orientale et Occidentali, Libri 12.” In the first book we have an account of the affairs of the East, civil and ecclesiastical, and the history of the country from the time of Mahomet to the year 1210. In the second a view of the state of ecclesiastical affairs in the West, during the same time; and in the third the history of the East to the year 1218. The book was written by a man of talents adapted to the various concerns in which he engaged, and he was steadily devoted to the interests of the holy see.

James, Thomas, a learned English divine and critic, who flourished in the seventeenth century, was born at Newport, in the Isle of Wight, about the year 1671. He was initiated in grammar learning at Winchester school, and was thence sent to New college, Oxford, of which house he became a fellow in 1693. In 1699, having collected many MSS. he published “Philobiblon Richardi Dunelmensis,” with an appendix, “De Manuscriptis Oxonienisis.” This he dedicated to Sir Thomas Bodley, who afterwards appointed him to the office of librarian of the library which he was then building. In 1696, Mr. James published “Educe Oxonio-Cantabrigiensiis,” containing a catalogue of all the MSS. in each college library at Oxford, but not those in the public library, and in each college library, as well as the public one, at Cambridge. In 1695, he printed “Catalogus Librorum in Bibliotheca Bodleiana,” and shortly after he applied himself to examine the state of all the public libraries in England. In the year 1614 he obtained considerable promotions in the church without solicitation. In 1620 he resigned his office as keeper of the Bodleian library, in order that he might have less interruption in his studies, the chief object of which was the defence of the Protestant church against the Papists. He died at the early age of 51, leaving behind him the character of being the most industrious and indefatigable writer against the Papists of any who had been educated at Oxford since the Reformation. He was author of many other works besides those already mentioned; the titles of which may be found in Wood’s Athen Oxon. See also Bibl. Brit. Supplement.

James, Richard, nephew of the preceding, was also a native of Newport, in the Isle of Wight, brought up to the church, and entered into holy orders. About the year 1619 he travelled for improvement through Wales and Scotland, whence he proceeded to Shetland, Greenland, and Ruffia; on the last named country he wrote observations, as well as on the manners and customs of the inhabitants. On his return he allevied the celebrated Selden in the composition of his work entitled “Marmora Arundeliana,” which was published in 1628. He was also serviceable to Sir Robert Cotton, and his son Sir Thomas, in polishing and setting their noble library, and with the former of these he was committed close prisoner by order of the house of lords in 1639. During his confinement he composed some verses, which he prefixed to a copy of all his printed works, and presented it to the Bodleian library, a short time before his death. He died in December 1648, leaving behind him forty-five MSS. of his own composing or collecting, all in his own handwriting, which were afterwards placed in the Bodleian library. He was regarded by all who knew him to be a very good Greek, poet, critic, antiquary, and divine; and admirably well filled in the highest and chiefest of the languages. He was engaged by his uncle to assist in collating the MSS. of the fathers, with the Popish editions, in order to detect the forgeries and omisions in these last. He seems never to have obtained any preferment in the church, though his uncle pleaded hard for him with the celebrated Usher. In a letter to this archbishop, having mentioned our author’s engagement in writing the life of Becket, he recommends him to the prelate in these words: “This kinman of mine, as well as myself, should be right glad to do any service to your lordship in this kind. He is of strength, and well able and learned to effectuate somewhat in this kind, the Chiffîn both in Hebrew, Greek, and Latin, knowing well the languages, both French, Spanish, and Italian; immense beyond all other men in reading of the MSS.; of an extraordinary life in penning; such a one as I dare balance with any priest or defient in the world of his age, and such a one as I could wish your lordship had about you, but ‘paupertas inimica bonus est moribus,’ and both father- lefs and mother-lefs, and almost, but for myself, I may say, (the more is his pity) friendless.” Bibl. Brit.

James of the Sword, St., San Jago del Espada, a military order in Spain, the most honourable and opulent of the three Spanish orders, instituted in 1170, under the reign of Ferdinand II King of Leon and Gallicia. The other two orders, viz. those of Calatrava and Alcántara, though inferior to that of St. Jago in power and wealth, were nevertheless very considerable.

Its end was, to put a stop to the incursions of the Moors; these knights, obliging themselves by a vow to secure the roads, and to defend the pilgrims on their journey to visit the relics of St. James of Compostella.

An union was proposed and agreed to in 1170 between thefe and the canons of St. Eloy; and the order was confirmed by the pope in 1176. At that time a considerable part of Spain was subject to the Moors, and the whole country much exposed to the depredations not only of the enemy, but of banditti. It is no wonder then, that an institution, the object of which was to oppose the enemies of the Christian faith, and to retrain, and punish those who disturbed the public peace, should be extremely popular, and meet with general encouragement.

The highest dignity in this order is that of grand-master, which has been united to the crown of Spain. The knights are obliged to make proof of their descent from families that have been noble for four generations on both sides; they must also make it appear, that their fad ancestors have neither been Jews, Saracens, nor heretics; nor even to have been called in question by the inquisition.

The novices were obliged to serve six months in the galleys, and to live a month in a monastery. Heretofore they were truly religious, and took a vow of celibacy; but Alexander III. gave them a permission to marry. They now make no vows but of poverty, obedience, and conjugal fidelity; to which, since the year 1652, they have added that of defending the immaculate conception of the Holy Virgin. The badge of the order is a cross of gold, enamelled crimson, charged on the centre with a calthop shell argent, and worn round the neck pendant to a broad green ribbon. Their habit is a white cloak, with a red cross on the breast. This is esteemed the most considerable of all the military orders in Spain; the king carefully preserves the office of grand-master in his own family; on account of the rich revenues and offices thereof it gives him the dipsofé. The number of knights is much greater now than formerly, all the grandees choosing rather to be received into this than into the order of the Golden Fleece; inasmuch as this Parliament is dissolved, not only in the religious aspect of attaining to commands, and gives them many considerable privileges in all the provinces of Spain, but especially in Catalonia. The knights are most implicitly
implicitly to obey the commands of their grand master. The order could formerly bring into the field 1000 men at arms; and if they were accompanied as was usual in a former age, this was a formidable body of cavalry. To this order there belonged 84 commanderies and 200 priories, and other benefices.

There was an order of the same name and kind instituted in Portugal by king Don Luis I., fornamed the Liberal, who, in the year 1288, obtained a bull from pope Nicholas IV. for the separation of the order from Spain; and in the year 1486, pope Alexander VI., at the solicitation of John II., revoked the vows of celerity, and allowed all the knights of this order in Portugal to marry. The reigning king of Portugal is grand master of the order. The badge and ribbon are nearly the same with those of the Spanish order.

Another order under the same denomination, being a religious order for ladies, was instituted at Salamanca, in Spain, in the year 1312. Their habit was black, their badge, which they wore on the left breast, was a crown fleury fitted embroidered gules, charged on the centre with an escutcheon.

James, St., Order of, was instituted in Holland in the year 1290. By Florence V. count of Holland. The knights were 12 in number. The collar of the order was a chain of gold, in which, at equal distances, were placed six escutcheons; and pendant to this collar was a medallion of gold with the image of St. James enamelled upon it.

James's Day, St., a festival in the calendar, observed on the 25th of July, in honour of St. James.

James's Bay, in Geography, the easterm part of the south division of Hudson's bay, with which it communicates, dividing New Britain from South Wales. It is about 150 miles wide. N. lat. 51° 10' to 55° 10'. W. long. 58° 30' to 82° 45'. Sue Hudson's Bay.

James's Cape, St., the southernmost extremity of Queen Charlotte's island, discovered by captain Dixon in 1787, on the 25th of July, whence its name. Captain Vancouver fixcs its situation in N. lat. 51° 58'. E. long. 129° 6'.—Alfo, a cape on the coast of Chippa, in the Chinefe sea. N. lat. 10° 32'. E. long. 106° 43'.

James City, a county of Virginia, in the United States, 30 miles long and 12 broad, lying between Chickahominy and James's rivers, containing 1542 free inhabitants, and 2318 slaves.

James Fort, a fort of the island of Barbadoes, near Bridgetown. Alfo, a fortresses of Africa, in the kingdom of Africa, on the Gold coast. Alfo, a fort on the N. side of Lobillo bay, in the island of Antigua, at the head of which is St. John's harbour.

James Island, an island of America, situated in South Carolina, on the south side of Charlestown harbour, opposite to Charleston, and containing about 50 families; separated from John's island on the westward by Stono river.—Alfo, an island of Africa, 30 miles up the river Gambia, where the English have a fort and factory. Alfo, a small island near the coast of Maryland, in the Cheapeak. N. lat. 38° 40'. W. long. 76° 25'.

James River, a navigable river of America, in Virginia, recently called by the Indians "Powhatan," formed by the junction of James's and Cowpap Afro rivers, which are nearly equal. At the place where it begins to break through the Blue ridge it receives the North river, and in its course between the Blue ridge and Richmond receives several other streams. At Richmond the navigation is interrupted by falls; but a canal serves for the passing of boats by these falls. Above these the river is navigable for batteaux and canoes to within 10 miles of the Blue ridge. It is not improbable that its navigation may at some future period be made to interlock with that of the Pottowmac, and thus to communicate by a short passage with the Ohio. James river, after a course of between 200 and 300 miles, falls into the mouth of the Cheapeak. N. lat. 37° 2'. W. long. 76° 20'.

James, a creek in Delaware, which empties into Delaware bay, 11 miles below Hook island. Down, the seat of government, stands on this creek, 5 miles from its mouth.

James, St., a town of South Carolina; 15 miles N. of Charlestown. Alfo, a town of South Carolina, on the S. side of the Santée; 44 miles N. of Charlestown. N. lat. 33° 29'. W. 79° 28'.—Alfo, a town of the state of Maryland, in Kent county, 4 miles S.W. of Chester. Alfo, a town of France, in the department of the Channel, and chief place of a canton in the district of Arvanches; 9 miles S. of it. The place contains 2522, and the canton 12459 inhabitants, on a territory of 1554 kilometres, in 12 communes.

James's Islands, St., the greater and less, two of the smaller Virgin islands, situated in the King's channel E. of Tortola, and W. of St. Thomas; between which and there is St. James's passage.

James's River, St., a river of Canada, which runs into the river St. Lawrence, N. lat. 48° 10'. W. long. 69° 10'.

James's Powder, in the Materia Medica, a famous preparation of antimony, the receipt for which, as extracted from the records of chancery, is as follows:—Take antimony, calcine it with a continual protracted heat in a flat unglazed earthen vefsel, adding to it from time to time a sufficient quantity of any animal oil and salt, well dephlogiſicated; then boil it in melted nitre for a confiderable time, and separate the powder from the nitre by dissolving it in water. Take quickfiver, make an amalgam with equal parts of the martial regulus of antimony and pure filver, adding a proprional quantity of fal ammoniac. Diffiſh the mercury by a retort into a glafs receiver, then with the quickfiver make a fresh amalgam with the fame ingredients; diffiſh again, and repeat this operation nine or ten times; then difliſh this mercury in spirits of nitre, and put it into a glafs retort and difliſh to dryneses; calcine the caput mortuum till it becomes of a gold colour; burn spirits of wine upon it, and keep it for use. The dote of the powder is uncertain; in general, 30 grains of the antimonial powder and one grain of the mercurial is a moderate dose. Signed and sworn to by Robt. James. It is fuppofed, however, that in water, the fpiritual procefs was formed upon one previously brought from Italy, which had its run in the family of the refpeftable parson called "Lill's powder," and the preparation of which, was very analogous to the preſent "Pulvis antimonialis," for an account of which, fee ANTIMONY.

In the 2d part of the 8th volume of the Philosophical Transactions (for 1791) we have an elaborate paper, containing a great number and variety of 'Experiments and Observations to investigate the Composition of James's Powder.' Thes experiments and observations are the more important and useful, as they serve to explain the nature and manner of preparing this medicine, to which many physicians have acceded, and upon which they have principally depended for the cure of continued fevers; and more especially as this patent medicine cannot be prepared by following the directions of the specific in the court of Chancery. Our limits will not allow us to give a minute detail of the author's experiments; but we must content ourselves with extracting some of the general results, and refer the reader for further satisfaction to the valuable paper itself. From the above experiments it appeared probable
that such a substance as James's powder might be made by calcining together antimony and bone-ashes; which operation produces a powder called "Lilte's" and "Schavanberg's" fever powder; a preparation described by Schroder and other chemists above 150 years ago. The receipts for Lilte's and Schavanberg's powder differ in the proportion of the antimony to the bone-ashes, and in the state of the bone; some directing bone-flavages to be previously boiled in water; others ordered them to be burnt to ashes before calcining them with antimony; and in other prescriptions the bone-flavages were directed to be burnt with the antimony. According to the receipt in the possession of Mr. Bromfield, by which this powder was prepared above 60 years ago, and before any medicine was known by the name of James's powder, two pounds of harthorn-flavages must be boiled to dissolve all the mucilage, and then being dried, be calcined with one pound of crude antimony, till the fleece of sulphur ceases, and a light grey powder is produced. The same prescription was given to Mr. Wallis, about the same time, by Dr. John Eaton, of the College of Physicians, with the material addition, however, of ordering the calculated mixture to be exposed to a great heat in a close vessel to render it volatile. Mr. Turner made this powder, about 50 years ago, by calcining together equal weights of burnt harthorn and antimony in an open vessel, till all the sulphur was driven off, and the mixture was of a light grey colour. He likewise was acquainted with the fact, that by a sufficient degree of fire in a close vessel this cinnabar powder turned white. Mr. Turner also prepared this powder with a pound and a half of harthorn flavages and a pound of antimony, as well as with smaller proportions of bone. Schroder prescribes equal weights of antimony and calcined harthorn; and Potterius and Michaelis, as quoted by Frederic Hoffman, merely order the calcination of these two substances together (affirming no proportion) in a reverberatory fire for several days. In the London Pharmacopea of 1788, this powder is called "Pulvis anti-
monialis," and it is directed to be prepared by calcining together equal weights of harthorn flavages and antimony.

From the whole of his analytical experiments Dr. Peacock infers:

1. That James's powder consists of phosphoric acid, lime, and antimonial calx, with a minute quantity of calx of iron, which is considered to be an accidental subsistence.

2. That either thefe three essential ingredients are united without the addition of a third compound, or, phosphorated lime is combined with the antimonial calx, composing a double compound, in the proportion of about 37 parts of calx, and 43 parts of phosphorated lime.

3. That this antimonial calx is different from any other known calx of antimony in several of its chemical qualities. About three-fourths of it are soluble in marine acid, and afford Algaroth powder; and the remainder is not soluble in this menstruum, and is apparently vitrified.

From the author's feathetic experiments it appears, that by calcining together bone-ashes, that is, phosphorated lime, and antimony in a certain proportion, and afterwards exposing the mixture to a white heat, a compound was formed confining of antimonial calx and phosphorated lime, in the same proportion; and polishing the same kind of chemical properties, as James's powder.

A powder, says Dr. Pearson, fold by F. Newbery under the title of "James's powder for hordes, horned cattle, hounds, &c." is a light clay-coloured, gritty, talkefuls substance, in which are seen small 

 fingerprints. He says, it appears to me to be nothing more than James's powder for fevers, or Lilte's powder, above-mentioned, made by calcining antimony and bone-ashes together in open vessels; because, if, by exposure to a white heat in clofe vessels, it turns as white as James's powder; zndy, it diffuses partially in nitrous acid; and the remainder diffuses partially in marine acid. The nitrous solution contains phosphoric acid and calcareous earth, and the nitric solution affords Algaroth powder.

JAMESPOUR, in Geography, a town of Hindoostan, in Balogilfan; 23 miles S.W. of Dadar.

JAMESTOWN, a village of the county of Leitrim, province of Connaught, Ireland, which before the union returned two members to the house of commons. It is on the river Shannon, one mile from Drumfis, which is its post-town; three from Carrick on Shannon; and 73 N.W. from Dublin.—Alfo, a town of America, in Rhode island. See CANNONICAT.—Alfo, a polt town, formerly the metropolis of Virginia, and now the capital of James city county. It is the oldest town settled by the English in America. It is situated on a peninsula, on the N. side of James river, at its mouth in Chesapeak bay, eight miles S.S.W. of Williamsburg. N. lat. 37° 9'. W. long. 76° 50'.—Alfo, a town of Prince Edward county, in Virginia, situated on Appomatox river, 12 miles N.E. from the court-houfe. Alfo, a town of the island of Barbadoes, founded in the latter end of the year 1624, being the first English settlement in the island; situated in St. James's parish, on the W. side of the island. JAMEZ, or YAM, a town of Africa, in the kingdom of Fonia. N. lat. 12° 30'. W. long. 15° 11'.

JAMGONG, a town of Hindooistan, in Dowlatabad; 10 miles W. of Amednagar. Alfo, a town in the ciscar of Aurungabad; 15 miles E.N.E. of Aurungabad. Alfo, a town of Bengal; 58 miles N.W. of Bardwan.

JAMIA, a town of Sweden, in the province of Blekingen; nine miles E. of Carlcrone. JAMILA, a town of Hindooistan, in the ciscar of Banfwalk; 18 miles E. of Tandla.

JAMMING, in general, denotes the art of enfelcing any object between two bodies, so as to render it immovable.

In Sea Language, this expression is applied to the situation of some running rope, when it happens to be squeezed by the compression of the standing-rigging, &c. and consequently incapable of performing its office, by traversing in the blocks, till it is released. In this sense jamming is opposed to rendering.

JAMNEY, in Geography, a town of Bohemia, in the circle of Chrudin; 17 miles N.E. of Leutac.

JANNA, JANNIA, or JAYNA, in Ancient Geography, a maritime town of Palestine, between Azotus and Joppa, which belonged to the Philistines; but taken from them by Uzziah, king of Judah, 2 Chron. xxvi. 6. According to Josephus, it was given to the tribe of Dan. It was taken by Judas Maccabæus, who burnt its port and its vessels. In the 2d book of Maccabees, xii. 9. it is said to be distant from Jerusalem 240 furlongs. Stephan. Byz. assigns it to the Phenicians. Augustus gave it to Herod, and this prince transferred it to his fitter Salome, who at her death, bequeathed it to Livia, the wife of Augustus. Under the reign of Nero, it was taken by Vetaianus, A.D. 67. After the conquest of Judea by Vespasian and Titus, an inconsiderable body of the Jews or Swabians, under others withdrew; and collecting the scattered fragments of Jewish learning from the general wreck into a school at Jafna or Jamnia, revived in this place their forms of worship. The rabbi Jehoanan was the founder of the school; and the good design which he began was completed, as far as the state of the times would allow, by the rabbi Gamaliel, called from this circumstance Gamaliel-Jafniensis. The success which attended this
school induced many of the dispersed Jews to return to Palestine; and another school was formed at Tiberias.

JAMNITZ, or Geuzmatz, in Geography, a town of Moravia, in the circle of Znaim; 22 miles N.W. of Znaim. N. lat. 48° 59'. E. long. 15° 28'.

JAMOOGONG, in Geography, a town of Hindoostan, in the circuit of Aurungabad; 20 miles E. of Jafferaabad.

JAMNUP, in our Old Writers, furze, or gorze, and gery ground. This word is used in fields of lands, &c. and seems to come from the French jaune, i.e. yellow; because the blossoms of furze or gorze are of that colour. 1 Croke 1797.

JAMPOLI, in Ancient Geography, a town of Greece, in Laceda;

JAMPUR, in Geography, a town of Hindoostan, in Guzerat; 17 miles N. of Khandunpur.

JAMPUR, in Geography, a town of Hindoostan, in Guzerat; 17 miles N. of Khandunpur.

JAMPSA, a town of Sweden, in Tavalland; 56 miles N.E. of Tavalthus.

JAMSMIO, a town of Sweden, in the province of Blekingen; 32 miles W. of Carlscrona.

JAMTLAND, a province of Sweden, bordering upon Norway, about 70 miles in length and 60 in breadth, annexed to the crown of Sweden by the treaty of Roschild, in the year 1658. It is generally mountainous; on the western part the rocks are craggy and the mountains high, having between them deep valleys and rapid torrents. The milk of the cows, bred in these pastures, and housed even in summer, furnishes excellent butter, but they are supplied with beef and tallow from Norway. The eastern part of the province is a champaign country, watered by lakes and rivers which abound with fish; and the neighbouring provinces are occasionally supplied with grain, chiefly barley, oats, and rye, and some wheat from the fertile spots in this district. The Jamslanders in severe feasts are reduced, by the fearcness of corn, to the necessity of preparing bread from the pulverized bark of trees. The iron ore of this province furnishes employment for many persons; and they have also alum quarries, slate, lead-ore, and other minerals, two copper-works of modern erection, and a place for making faltpetre. The population is inconsiderable, so that the tallow-factories are required to perform all other parts; and at distant intervals. The towns are few, and in the 11 parishes which Jamtland contains, 46 churches have been erected: the number of chimneys in all these parishes amounts to about 717. The inhabitants derive their subsistence from agriculture, grazing, hunting, and fishing. With the Norwegeians they carry on a considerable trade, supplying them with salt-pans, flax, and iron-ware; and a kind of leather, impregnated by water, of which are made shoes, boots, and even jackets. This country, by the contributions of the peasants, maintains a regiment of foot, or, as others say, of dragoons, and a troop of horse.

JAN, a town of Japan, in the island of Niphon; 25 miles of Secoda.

JAN, among the Romans, a name given to Diana, or the moon.

JANAGAVA, in Geography, a town of Japan, in the island of Ximo; 20 miles S.E. of 1kou.

JANAGUR, a town of Hindoostan, in Guzerat, on the right bank of the Padder; 100 miles W. of Amadabad. N. lat. 23° 50'. E. long. 70° 56'.

JANAKA, a rajah, according to Hindoo legends, who being childless, adopted a female infant found in a field by a ploughman. This child proved eventually to be an avatar, or incarnation of Lakshmi, consort of Vishnu, for the purpose of accompanying her lord on earth in his manifestation in the person of Rama. As the daughter of Janak he is sometimes called Janaki, but her most common name in India. See Sita.

JANAKALA, in Geography, a town of Sweden, in the province of Tavalland; 16 miles N.N.W. of Tavalthus.

JANALAX, a town of Sweden, in the province of Savola; 35 miles N.N.W. of Nyklo.

JANEIRO, Rio. See Rio Janeiro.

JANEMAY, James, in Biography, an English non-conformist divine, was educated at Christ-church college, Oxford. After the Restoration he was deprived of his living in the church, and gladly opened a meeting-house at Rochester, when the act of indulgence was passed. He died in 1674. He was author of "Heaven upon Earth;" "The Saints Encouragement to Diligence;" and "A Token for Children," which has been exceedingly popular and gone through a multitude of editions. Calamy.

JANGAGUR, in Geography, a town of Hindoostan, on the Nerbuddah; 15 miles W. of Hordah.

JANGARA, a town of Bengal; eight miles N.N.E. of Curuckpour.

JANGAS, a town of Peru, in the diocese of Guamanga; 15 miles E. of Lanaguana.

JANGEGUR, a town of Hindoostan, in the circuit of Ruttumpour; 38 miles S. of Ruttumpour.

JANGIPOUR, a town of Bengal; 18 miles N.N.W. of Moorshedabad.

JANGOMA, or JANGOMA, a small kingdom of Asia, in the vicinity of the Brman empire, on the north of Siam. Its extent has been variable on account of its frequent revolutions. According to the Sianese reports, this country is governed by priests. The inhabitants are said to be of tall and well proportioned; and in this hot climate their sole garment is a cicature of linen. The women are famed in the East for their gallantry and beauty, in which last quality they surpass the girls of Pegu; and voluptuous monarchs think their harems enriched and adorned by a concubine from Jangoma. The common food of the inhabitants is rice, and the country is also said to abound in mulk, pepper, silk, gold, silver, copper, and gum-benzoe. Little that is certain, however, is known concerning this remote country.

JANGON, a town of Asiatic Turkey, in Caramania; 18 miles N. of Kaifarik.

JANGUIRA, a town of Hindoostan, in Bahar; 13 miles W. of Boglipour.

JANGURABAD, a town of Hindoostan, in the circuit of Sumbul; 10 miles S.W. of Anapheer.

JANGURPOUR, a small circuit of Bengal; W. of Dagepeour.

JANI, a town of Asiatic Turkey, in the government of Sivas; 62 miles S.S.W. of Sivas.

JANJACOPET, a town of Hindoostan, in Bednore; 26 miles W. of Simogu.

JANICULUS, or JANICULARIS, Mons, in Ancient Geography, a mountain of Rome, having to the E. and S. the Tiber, to the W. the fields, to the N. the Vatican; and so much of it as stands within the city-walls is about five stadia in circuit. It was so called either from an old town of the same name, said to have been built by Janus; or because Janus dwelt and was buried there; or because it was a sort of gate (Jama) to the Romans, whence they flied out upon the Tufcans. The sparkling fountains have at present given it the name of "Mons Aureus," and by corruption "Monterius." This eminence afforded the best situation for a full prospect of the city; but it has been left inhabited than the other parts on account of the groines of the ar.
It is still famous for the sepulchres of Numa, and the poet Staturis. Ancus Martius encompassed the Janiculum with a wall; and for a communication between this place and the city, he built over the river a timber-bridge, of an extraordinary structure, whose parts were held together without being linked with iron. The pontifices were appointed to keep possession of the bridge.

**JANIDUNI**, in Geography, a town of European Turkey, in Becharabia, situated on the Black sea; 40 miles W.S.W. of Otschakow.

**JANIKAU**, or **JANKOW**, a town of Bohemia, in the circle of Czaslau; six miles S.E. of Czaslau.

**JANISZKI**, a town of Samogitia; 56 miles N.N.E. of Miednik.

**JANITORES**, door-keepers among the Romans, the meanest of their slaves, who were commonlychained to their pots.

**JANIZARIES**, an order of infantry in the Turkish armies; reputed the grand seignior's foot-guard.

Volfin derives the word from geniezer, which, in the Turkish language, signifies noun bonum, or militis. D'Herbelot tells us, that junitscheri signifies a new band or troop; and that the name was originally given by Amurath I. called the Conqueror, who, choosing out one-fifth part of the Christian prisoners whom he had taken from the Greeks, and instructing them in the discipline of war and the doctrines of their religion, sent them to Hagi Bektachli (a person whose pretended piety rendered him extremely revered among the Turks), to the end that he might confer his blessing on them, and at the same time give them some mark to distinguish them from the rest of the troops. Bektachli, after blessing them in his manner, cut off one of the fingers of the fur gown which he had on, and put it on the head of the leader of this new militia; from which time, viz., the year of Christ 1261, they have still retained the name junitscheri, and the fur cap. Others ascribe their origin to Sultan Amurath II. in the year 1572, and others again to Orcan, the predecessor of Amurath I.

The janizaries are children of tribute, levied by the Turks among the Christians, and bred up to the military life. They are taken at the age of twelve years, to the end, that forgetting their country and religion, they may know no other parent but the sultan. However, generally speaking, they are not now a-days raised by way of tribute; for the carach, or tax, which the Turks impose on the Christians, for allowing them the liberty of their religion, is now paid in money; excepting in some places where money being scarce, the people are unable to pay in specie, as in Mungrelia, and other provinces near the Black sea. At present the Turks make no scruple of recruiting their janizaries with natives; and as there are some of these troops in the provinces as well as at Constantinople, it is not easy to ascertain their number. At first this military corps consisted of no more than 12,000 men, and they seemed to be particularly designed as a guard to the emperor's person; and it was afterwards augmented by the succeffors of the founder to 50,000. Selim, the son of Bajazet, reduced them; but since his reign their number has again so increased, that they have composed the principal force of the Turkish army.

As in the Turkish army, the European troops are distinguished from those of Asia, the janizaries are also distinguished from the janizaries of Constantinople, and of Damascus. At Constantinople Sultan Soliman built barracks for the janizaries, and belloved a splendid gilding on the edges of the porticoes, which his succeffors have always maintained, though they have entirely neglected the discipline which he established. This disregarce of good order, by totally destroying the spirit of the institution, has increased the number of those who receive pay.

Their pay is from two aspers to twelve per diem; for when they have a child, or do any signal piece of service, their pay is augmented. Baron de Tott says, that the pay of the janizaries is only distributed every three months; and that it has a progressive increase from three aspers to ninety-nine.

Their drefs consists of a dolyman, or long gown, with short sleeves, which is given them annually by the grand seignior, on the first day of Ramazan. They wear no turban, but in lieu of that a kind of cap which they call neref; and a long hood of the same stuff hanging on their shoulders. On felemun days they are adorned with feathers, which are stuck in a little cafe in the fore-part of the bonnet. On occasions of this kind the janizaries appear without arms, and with their hands crossed before them; and except the red shoes, great blue breeches and bonnet which they are obliged to wear, they drefs themselves in whatever colour they please, and their uniform consists only in the cut of their clothes.

Their arms in Europe, in a time of war, are a sabre, a carabine, or musket, and a cartouch-box hanging on the left side. At Constantinople, in time of peace, they only carry a long staff in their hand. In Asia, where powder and firearms were more uncommon, they wore a bow and arrow, with a poignard, which they called baniare.

The officer who commands the whole body of janizaries is called the janizar ogagi; in English, age of the janizaries. He is one of the chief officers of the empire.

The corps of janizaries is divided into regiments, which are called "Baluck," and the commander of every regiment is denominated "Baluck-Aga." these regiments are distributed into barracks, or "odas," the soldiers of which live together, when they are at Constantinople or in the provinces. M. de Peyroles, in his "Strictures on the Memoirs of Baron de Tott," mentions the division of them into "Ortas," "Bulucks," and "Seymens," forming in all 196 companies, i.e. 101 ortas, 61 bulucks, and 34 seymens. These companies are again subdivided. To this corps also belong the "Yerlis," or provincial militia of the janizaries, commanded by a "Serdar," in the cities which are not considered as places of strength, and where they have no janizary-aga; also the "Yamaks," or garrisoned invalids; and the "Otouraks," or invalids exempted from service. In the garrison and in the field they are divided into "Sag Kol," and "Sol Kol," or right wing and left wing, each of which has its separate standard and respective aga, one of whom is called "Sag Kol Agafi," and the other "Sol Kol Agafi." There are also companies of volunteers, which are raised in time of war, and maintained by the officers at their own expense. To this class of military also belong gunners, bombardiers, pioneers, miners, &c. In the army the janizaries encamp together by tens; every ten having a horse to carry their small baggage and cloaks, with a servant to cook for them; and every twenty a camel to carry two tents, two large carpets on which to sleep, two kettles, and two leather vessels in which to carry water; when they cannot get camels, they make use of waggons furnished by the country through which they pass. With regard to their tactics, they form their battalions very deep, and their squa- drons very large; they are exercized in the use of their arms, and to preserve their ranks and files; but with less order and exactness than the troops of the Christians. They never had pikes, but their favourite weapon has always been the feymetar. In former times they fought with darts, arrows, and hatchets; but, at present, the whole of their

infantry
infantry is provided with firelocks. M. de Bonneval attempted to instruct them in handling the bayonets, and formed a small body to the use of that weapon; but it declined and dwindled away since his death. Their ordinary mode of fighting is to fire their pieces and then fall on the enemy, fabric in hand, with very little order, notwithstanding which their number, their impetuosity, and the weight of their shock, render them very formidable, particularly in the first onset; after one or two repulses their fury abates, and it is not easy to bring them again to the charge.

Though the janizaries are not prohibited marrying, yet they rarely marry, nor then, but with the consent of their officers; as imagining a married man to make a worse soldier than a bachelor.

The janizaries were at first called ϒεας, that is, footmen, to distinguish them from the other Turks, the troops whereof consisted mostly of cavalry.

Vigenere tells us, that the discipline observed among the janizaries is extremely formidable, in a great many things, to that used in the Roman legions.

The janizaries were formerly a body formidable even to their masters, the grand signorians. They depopulated Bajaet II. in 1512; they procured the death of Amurath III. in 1525; And in 1622, but re-footmen, deprived them of the use of their hands, and then fell on the enemy, fabric in hand, with very little order, notwithstanding which their number, their impetuosity, and the weight of their shock, render them very formidable, particularly in the first onset; after one or two repulses their fury abates, and it is not easy to bring them again to the charge.

The janizaries were at first called ϒεας, that is, footmen, to distinguish them from the other Turks, the troops whereof consisted mostly of cavalry.

Vigenere tells us, that the discipline observed among the janizaries is extremely formidable, in a great many things, to that used in the Roman legions.

The janizaries were herebefore a body formidable even to their masters, the grand signorians. They depopulated Bajaet II. in 1512; they procured the death of Amurath III. in 1525; And in 1622, but re-footmen, deprived them of the use of their hands, and then fell on the enemy, fabric in hand, with very little order, notwithstanding which their number, their impetuosity, and the weight of their shock, render them very formidable, particularly in the first onset; after one or two repulses their fury abates, and it is not easy to bring them again to the charge.

It is true, avenges itself by ordering the most active mutineers to be strangled; but, at the first opportunity that occurs, the janizaries create other chiefs, and affairs return to their usual course. The Pachas, feeming themselves thwarted by this national militia, have had recourse to the expedient practised in similar cases; they have taken foreign soldiers into their service, who have neither friends nor families in the country. These are of two sorts, cavalry and infantry. The former are called Delibaches and Leventis, and the latter Megrenians, which see respectively.

In Egypt the janizaries, and also the Azabs, which two bodies of the military corps were formerly the terror of the Pacha, have been so degraded by the influence of the Mamlouks, that they are now as insignificant as himself. The cause of this has been the corrupt and wretched government of the Turks; for, previously to the insurrection of Ibrahim Kinya, the number of Turkish troops, which should consist of 40,000 men, infantry and cavalry, had been reduced to less than half that number by the absence of their officers, who deserted the pay to their own use. After Ibrahim, Ali Bey completely destroyed their consequence. He first disarmed all the officers who gave him unmanageable power; left unfilled the places that became vacant; deprived the commanders of all influence; and so degraded all the Turkish troops, that at this day the janizaries, the Azabs, and the five other corps, are only a rabble of artizans and vagabonds, who guard the gate of those who pay them, and tremble in the presence of the Mamlouks, in whom the whole military force of Egypt consists. See MAMLOUK.

JANIZARIES, at Rome, are officers or pensioners of the pope, called also participantes, on account of certain rights or duties which they enjoy in the annates, bulls, or expediem, and the Roman chancery.

Moll authors are mistaken in the nature of their office. The truth is, they are officers of the third bench, or college, called the Roman chancery. The first bench consists of writers, the second of abbreviators, and the third of janizaries; who are the kind of correctors and revisors of the pope's bulls.

JANKOONIES TOWN, in Geography, a town of Africa, in Loango, on the coast. S. lat. 4° 30'.

JANNIER, a town of Hindostan, in Guzerat, on the gulf of Cambay; 38 miles S. of Gogo.

JANNA, or JANNIA, a considerable town of European Turkey, in the province of Tephally, the sea of a Greek bishop, situated on a lake which communicates with the river Peneus, and gives name to the province; 40 miles W. of Larissa. N. lat. 40°. E. long. 21° 32'.

JANNANINS, in Modern History, the name which the negroes, in some of the interior parts of Africa, give to spirits which they apprehend to be the ghosts or souls of their ancestors, and which they go to the tombs to consult and worship. Every negro has his tuteur jannamin, and so has likewise every village, to whom private and public worship
A fool's errand is, to till the soil, and fetch the water, &c.

LANEQUIN, in Biography, a French composer, flourished early in the 16th century, during the most splendid period of the reign of Francis I., when, though we hear of but few great musicians at his capital, yet so many 

founded, particularly in the Low Countries, that music in parts became common from that school all over Europe; and Jannequin, though he is placed by Walther in the middle of the 16th century, must have flourished much earlier; as a 

curiosity composition by him, called "La Battaille," printed in the tenth book of "French Songs for four Voices or Instruments," is preserved in the British Museum, which,

though it did not appear in this edition, by Tyman Saffato, of Antwerp, till 1545, must have been composed long before that time; for the song was written and set on occasion of the 

famous and obstinate battle of Marignan, which lasted two days, and was fought during the first year of Francis I., 1515, between the French and Swiss, who disputed their 

passage to the Milanese.

As this composer feems the first who tried to prove that music as well as painting and poetry was an imitative art, we shall give the whole title of the book of French songs for 

doue or voices or instruments preferred in the British 

Museum.

"De Dixieme livre des Chanions, contenant La Battaille à 4, de Clement Jannequin, avec la cinquieme partie de Philippe Verdelot, 6 place, et deux Chaffes du Lievre à 4 Parties; et le Chant des Oyfeaux à 3, 1545.

"La Battaille, ou défaite des Suisses à la journée de Marignan; à 4 ou à 5, Clem. Jannequin.

"Le Chant des Oyfeaux, à 3, Nic. Gombert.

"Le Chaffe du Lievre, à 4. Incognito Authori.

In the Battel-piece, as well as in the other imitative pieces in the same collection, there are several long movements in the Battel, in which the noise and din of war, during this 

memorable conflict, are imitated. In the song of birds, and in each composition called: "The Chace," or hunting of the hare, the composers have severally tried to express the 

words with more exactness than we had seen attempted before. Indeed, the best counter-point and the most ingenious contrivances, with respect to musical composition, anterior to 

this period, are contained in the mazes and motets of the church, where nothing like expression, or even the true accent of words is attempted. But here, though clumsily 

done, we have specimens of musical imitations, it should seem, for the first time.

The name and works of Jannequin had penetrated into Italy early in the 16th century, as we find by Zarlino, the elder Dom's catalogue of music, Pietro Pontio, and Zacuxoo. 

A work of his, entitled "Inventions Musicales," in four

and five parts, was published at Paris and Lyons, 1544.

JANNI, St., in Geography, a small island in the Mediterranean, near the coast of Naples. N. lat. 39° 59'. E. long. 13° 52'.

JANNOCK, a kind of oat oat bread, much used in the northern parts of England, and made of four leaven.

JANOHAI, in Scripture Geography, a city of Ephraim, on the frontiers of the half tribe of Manasseth. Josh. xvi. 6. Eusebius places a town called "Jano," 12 miles from Schechem or Naplone, in the Acrabatene, and another 3 miles from Lega, south.

JANOURA, in Geography, a town of Hindooftan, in Bahr; 16 miles S.W. of Bahr. N. lat. 25° 8'. E. long. 85° 34'.

JANOW, a town of Poland, in the palatinate of Ka-
conformable to the doctrine of scripture, and the decisions of the ancient fathers, than the opinions of Athanasius, which were patronized by the Jansenists. The former, they contended, inclined to the tenets of Augustine, and the latter bore a striking resemblance to the Pelagian heresy. In consequence of this declaration, Clement seemed resolved to condemn the Jansenists, and to determine the controversy in favour of the Dominicans. In 1662 the Jansenists prevailed on the old pontiff, by intertreaties, menaces, arguments, and complaints, to re-examine this intricate controversy, and to undertake the office of principal arbitrator. For this purpose he chose a council, called the congregation de auxiliis, or the congregation of aids, composed of 15 cardinals, nine professors of divinity, and five bishops, which, in the space of three years, assembled 78 times. The death of Clement, in 1663, prevented his pronouncing a decisive sentence with regard to this controversy; nor are his sentiments certainly known, though the Jansenists and Dominicans contend, that his decision would have been favourable to their respective party. The proceedings of this congregation were refamed, in 1665, by order of Paul V. the successor of Clement. The result of many solemn deliberations was, that the whole controversy, instead of being decided, should be suppressed; and that each of the contending parties should have the liberty of following their respective opinions. Paul V. declined a public determination of the controversy, through apprehension of offending either the king of France, who protected the Jansenists, or the king of Spain, who warmly maintained the cause of the Dominicans. The flame of controversy broke out again with new violence in the year 1650, on the publication of Janfenius’s book, which was divided into three parts: the first being historical, and containing a relation of the Pelagian controversy, which arose in the fifth century; in the second the author gives an accurate account and illustration of the doctrine of Augustine, relating to the constitution and powers of the human nature, in its original, fallen, and renewed state; and the third part contains his doctrine relating to the aid of sanctifying grace procured by Christ, and to the eternal predestination of men and angels. The deign of Janfenius, in this work, was to shew in what manner the important points in debate had been understood and explained by Augustine, whose name and authority were universally revered in all parts of the Roman Catholic world. The Dominicans, who followed the sentiments of Thomas Aquinas concerning the nature and efficacy of divine grace, derived very considerable advantage from this publication; whilst the Jansenists considered it as not only a tacit but formidable refutation of their opinions concerning human liberty and divine grace. They therefore exerted their most zealous endeavours to obtain a public condemnation of it from Rome; and they succeeded so far as to procure a prohibition of the peril of it, by the Roman inquisitors, in the year 1641; and in 1642 a solemn bull of Urban VIII. condemning it as fraught with several errors that had been long banished from the church. However, the decisions of the inquisition, and bull of the pontiff, were disregarded in many parts of the Roman church. The doctors of Louvain, the followers of Augustine in the Netherlands, and the abbot of St. Cyran, and other famous and learned men, known under the denomination of the Authors of Port-royal, in France, opposed the proceedings of the Jansenists, and fireniously supported the cause of Janfenius, though the greatest part of the French theologians engaged in behalf of the Jansenists. The dispute was now become very general and violent; and both parties exerted all their learning, art, interest, and power, to vindicate their respective cause. The Jansenists incurred to miracles in confirmation of their doctrine; and the history of the controversy furnishes many legendary tales of miraculous cures wrought in its favour: the first of these miracles occurs in 1656, when a pretended thorn of that derivative crown that was put upon our Saviour’s head by the Roman soldiers, is reported to have performed several wonderful cures in the convent of Port-royal: these were succeeded by other prodigies in the years 1661 and 1664. The fame pious frauds were revived in 1725, 1727, and 1731, when the bones of the Abbé de Paris, which were interred at St. Medard, are said to have been instrumental in performing innumerable miracles. However, the opposers of the doctrines of St. Augustine selected five propositions out of Janfenius’s book, which, by the interest and importunities of the Jansenists, were condemned by a public bull of Innocent X. in 1653. These propositions contained the following doctrines:

I. Some commands of God are impossible to righteous men, even though they endeavour, with all their powers, to accomplish them; the grace being wanting by which they should be enabled to perform them. II. In the state of corrupted nature, a man never refits inward grace. III. To merit and demerit in the present state of corrupt nature, it is not requisite a man should have that liberty which excludes necessity: that which excludes constraint is sufficient. IV. The Semipelagians admitted the necessity of inward preventing grace to each act in particular, and even to the beginning of faith; but they were heretics, in regard they affpired, that this grace was such as that the will of man might either refist or obey it. V. It is Semipelagianism to say, that Jesus Christ died, or shed his blood, for all men in general.

Of these propositions the pontiff declared the first four only heretical; but he pronounced the fifth rash, impious, and injurious to the Supreme Being.

The Janfenists, availing themselves of a subtle distinction invented by Arnaud, considered separately in this controversy the matter of doctrine, and the matter of fact, i.e. they acknowledged themselves bound to believe that the five propositions above mentioned were justly condemned by the Roman pontiff; but they maintained, that the pope had declared, and consequently, that they were not bound to believe, that these propositions were to be found in Janfenius’s book, in the fene in which they had been condemned. But this artful distinction was of no long service to them; for Alexander VII. issued a solemn bull in 1656, declaring, that the five propositions that had been condemned were the tenets of Janfenius, and were contained in his book; and in 1665 he forced France with the form of a declaration, that was to be subscribed by all who fought forerment in the church, affirming that the five propositions were to be found in the book of Janfenius, in the same fene in which they had been condemned by the church. This declaration produced the most deplorable tumults; the Janfenists maintained that the decisions of the pope, so far as they were not confirmed by a general council, with regard to matters of fact, were fallible; and the Jansenists, on the contrary, that unlimited confidence in the papal decisions, both with respect to matters of fact and of opinion, was an essential character of a well-grounded and divine faith. The Jansenists prevailed, and the Janfenists suffered exile, imprisonment, and various kinds of persecution. Clement IX. in consequence of the spirited remonstrance of several bishops, and the earnest application of Anne Genevieve de Bourbon, duchess of Longueville, accepted a conditional subscription to the declaration of his predecessor, allowing the Janfenists the privilege of interpreting it in their own sense. This indulgence restored tranquility, and produced a period in this controversy, commonly called the “Peace of Clement IX.”
but it was soon disturbed again by a public edict of Lewis XIV, and totally abolished after the death of the duchess of Longueville, in the year 1679. The famous Arnaud retreated on this occasion into Holland, where he gained over the Romish congregations to the Jansenist party: and this party, secured under the protection of the Dutch government, has since prevailed in that country. The Jansenists were particularly offensive to the Jesuits, on account of the austerity of their party, and the severity that reigned in their system of moral discipline and practical religion: for they have exclaimed against the corruptions of the church of Rome, both with regard to its doctrines and morals; and urged the necessity of instructing the people in the doctrines and precepts of Christianity; with this view they have maintained that the holy scriptures and public liturgies should be purified by the people in their mother tongue; and taught, that true piety does not consist in the observance of pompous rites, or in the performance of external acts of devotion, but inward holiness and divine love. This apparent piety of the Jansenists has, however, been unhappily blended with superstition and fanaticism; and they have been branded, not altogether without reason, with the denomination of Mylites and Rigourists. (See Quietism.) The controversy relating to Jansenism, which was one of the principal sources of that division which reigned within the papal jurisdiction, has been carried on with great animosity in France and the Netherlands; and the Jansenists were for a considerable time much inferior to the Jesuits in number, power, and influence, though they equalled their adversaries in resolution, prudence, and learning, and usurped them in facility of manners and superficiality, by which they excite the respect of the people. The United Provinces, particularly the Netherlands, have afforded them an asylum on many occasions: nevertheless the Jesuits, though they had no legal toleration in the republic, have gained ground among the Dutch papists. They had a flourishing chapel in the city of Utrecht, and places of worship in several other cities, and in a great number of villages. Towards the close of the 17th and the commencement of the 18th centuries, the cause of the Jansenists acquired reputation, by a French translation of the New Testament, made by the learned and pious Pachiatus Quened, a prelate of the Oratory; in the annotations to which he has artfully blended the quintessence of Jansenism. This work, at the instigation of the Jesuits, and particular application of Lewis XIV. to the court of Rome, was condemned by Clement XI, who, in 1713, lifted the famous bull Unigenitus, in which Quened's New Testament was condemned, and one hundred and one propositions contained in it pronounced heretical. The controversy relating to Jansenism was much heated and increased, instead of being mitigated or suspended, by this specious and ill-judged edict. The Jansenists were again obliged to recur to writing, and even to miracles and visions, and pretended revelations for the support of their declining cause. However, the form of repentance that afterwards arode against the Jesuits, and that has been attended with the extinction of their order in Portugal, France, and in all the Spanish dominions, has disarmed the most formidable adversaries of Jansenism, and must be considered as an event highly favourable to the Jansenists. Molinus's Eccl. Hist. vols. v. and vi. Eng. ed.

Jansenius, Cornelius, in Biography, a learned Flemish prelate, born at Hall in the year 1510, and educated at Ghent and Louvain, became a professor in the Hebrew, as well as Greek and Latin languages, and devoted himself to the study of the scriptures. After occupying some subordinate situations in the exercise of his ministry, he was appointed professer of divinity at Louvain, and admitted to the degree of doctor of divinity. In the famous council of Trent he commanded respect by his learning and modesty, and upon his return to Flanders in 1568, he was nominated the first bishop of Ghent, where he died in 1576. His works were: "A Paraphrase on the Psalms," with copious notes, in Latin, printed at Louvain in 1569; "Notes on the Books of Proverbs, Ecclesiasticus, the Canticles, and the Book of Wisdom," printed in 1586: "Commentaries upon some Passages in the Old Testament," &c. His chief work, however, was the "Concordia Evangelica," first printed in 1549 and frequently reprinted. Of this work Dupin says, that it is the most perfect harmony of the four gospels which had till that time appeared. To the author he pays a very distinguished tribute of respect, as a very able expounder of scripture, and eminently characterized by his learning, judgment and perspicuity. Dupin, Gen. Bio.

Jansenius, Cornelius, bishop of Ypres and founder of the Jansenists, was born at a village near Leerdam, in Holland, in the year 1531; and having commenced his studies at Utrecht, entered them at Louvain in 1562. Removing to Paris on account of the state of his health, which had been impaired by his arduous application, he renewed his connection with the abbot of St. Cyran, with whom he had commenced an acquaintance at Louvain. At Bayonne these two friends, after temporary separation met again, and concurred for five or six years in the study of the fathers, and particularly of St. Augustine. The abbot Du Verger was here promoted to a canonry in the cathedral, and Jansenius was placed at the head of a college. Upon Du Verger's removal to Paris, Jansenius returned to Louvain, and was soon appointed principal of the college of St. Palcheria. In 1617, he took his degree of doctor of divinity, and was admitted one of the professors of that faculty, in which office his talents and learning were conspicuously displayed. On occasion of the interference of the Jesuits with some privileges belonging to the university of Louvain, Jansenius was selected as a fit person to settle and vindicate their rights in an embassy to the king of Spain. For this purpose he made two journeys into that country, viz. in 1624, and in 1625; and in the year 1630 he was appointed by the king professor of the holy scriptures in the university of Louvain. In this year he engaged in a controversy with the Protestants; and this controversy produced on his part a piece entitled "Alexipharmacum," printed in 1632; another under the title of "Notarum Spionum," &c. in 1631. Another controversy of a similar kind engaged his attention in 1634, in the conduct of which he had recourse, in a manner that reflects disgrace on his name and memory, in measures of persecution against his adversary, instead of contenting himself with the more appropriate weapons of argumentation. In the year 1635 he published a work, which, however acceptable to his patron, the Spanish monarch, conferred no honour on the spirit of the writer; it was entitled "Alexandri Patricii Armacioni, Theologii, Mars Gallicis, seu Inscriptio Armorum et Frederum Regis Galliae Libri duo," and contains the most malignant and invidious exclamations against the services which were rendered by France to the Protestants of Holland and Germany, to the prejudice of the Romish religion. In consequence of this publication he was promoted to the bishopric of Ypres. His conduct on this occasion, and the publication of the above-mentioned book, are said to have first excited the enmity of cardinal Richelieu against the author and his followers, and the partizanship of the court in favour of the Jesuits. Jansenius, however, fell into the reform of his diocese; but was prevented from accomplishing the work which he had begun by his death, which happened in 1638, when he was about 53 years old.
He died highly respected for learning and other eminent qualifications, as well as for his piety and virtues. His works, besides those already mentioned, were "Tetrateuchus, five Commentaries in IV Evangelii," 4to. "Pentateuchus, five Commentaries in V libros Moyalis," 4to. "Analeccta in Proverbia, Ecclesiasten, Sapiantiam, Habacuc, et Sophonisam," 4to.: "De Vi obligandi Conscientias quam habent Editæ regia super Re Moneta;" "De Juramento quod publica Auctoritate Magistratui definito imponi solat;" "Oratio de interioris huminis Reformations;" and, more particularly delivering of mention, his "Augustinus, feu Doctiss. St. Augustini de Humanæ Naturæ Sanctitatem, Egregudinum, Medicae, adversus Pelagianos et Mysticiis," folio. This latter work occasioned the controversy, of which we have given an account under the article "JANSENIUM," to which the reader is referred. Dupin, Bayle.

Mothein.

JANSEN, JAMES, a learned theological professor at Louvain, was born of Catholic parents at Amsterdam in the year 1547, and completed his studies at Louvain, whether he was then for this purpose in 1564. In 1575 he was admitted a licentiate in divinity, and was afterwards nominated first president of the new Augustine college. Having rashed gradually to several offices of honour and duty in the church, he was at last, in 1614, appointed dean of the collegiate church of St. Peter's at Louvain; and died in 1625. Of his works, which have been held in high esteem, we shall enumerate "Expositio in Prophetam Job," folio; "Commentarium et Epistola in Psalm Davidos," 4to.: "Commentarius in Canticum Cantorum," 4to.: "Expositio in Evang. Joann," 4to.; "Institutio Catholicae Ecclesiae;" "Liturgia;" "In facrem Missæ Canonem;" "Enarratio Paffionis," &c. Moreri. 

JON-JACOB, in Geography, a town of Hinduolstan, in the circuit of Gohud; 110 miles S. of Agra. N. lat. 25° 32'. E. long. 78° 57'.

JANSON, MESSIAH. In Biography, two brothers, the most celebrated performers on the violoncello in France, at the time when M. Laborte published his "Effais sur la Musique," and consequently, according to that author, "the beauty of the universe." These were rivals of the two brothers, Duport, whose performance gave equal delight. It was hardly possible to play an adagio with more delicacy, taste, and feeling than the elder Janfons. The elder Duport's execution was truly astonishing; and it is among extraordinary circumstances, that four such performers on the same instrument should flourish at the same time in one city.

JANSESN, ABRAHAM, an historical painter, born at Antwerp in 1560. He excelled great powers in the practical parts of the art, and, neglectful and dissipated, he wasted those powers, and fell into indigence. Being contemporary with Rubens, he was mortified at the success of his younger rival, who drew from him the admiration of the public, and in a fit of ill humour challenged him to paint a picture for fame; defying to submit their reputation to impartial judges. This proposal was rejected by Rubens, who answered in a mild and becoming manner, that he submitted to him; and the world would do justice to them both. The churches of the Low Countries poffessed many excellent works of this master; but his chef-d'œuvre is the "Resurrection of Lazarus in the gallery at Dusseldorf.

JANSEN, HONORABLE. A painter, born at Brusels in 1661. Having applied sedulously to the practice of the art, and made much proficiency, he was employed by the duke of Holstein at a pension of 800 florins, and afterwards enabled, by the fame munificent patron, to pursue his studies in Italy.

In Rome he studied the works of Raphael, and became eminent in fame. He afterwards associated with Tencelli the landscape painter, and painted figures in his pictures.

In general his pictures are small in size, and have somewhat of the style of Albano. His invention was copious, and his works are very pleasing. He died in 1739, at the age of 75.

JANSSENS, CORNELIUS, called also Johnsen, a portrait painter of very extraordinary merit. He was born at Amsterdam; when, is not exactly ascertained. It appears that he painted in England as early as the year 1618, in the reign of James I. He continued to paint with very great and deserved success till the arrival of Rubens, whose transcendent talents and taste Janfens was not quite equal to cope with. On the breaking out of the civil war he returned to his own country, in 1648; leaving behind him a number of excellent charactertistic portraits in the great families of this island.

He retired first to Middleburg, and afterwards to Amsterdam, where he died in 1665.

His style of design was formal and void of taste, but his features are justly marked, and the faces of his portraits have great character, and an air of nature, possessing much sweetness of bone in the colouring, and finished very highly; too much I must say. His pictures are generally on wood, and with black draperies; an arrangement adopted frequently by Rubens and Vandycke.

JANECA, in Geography, a town of Hinduolstan, in the circuit of Adoni; 59 miles N.W. of Adoni.

JANUARIUS, ST., in Biography, bishop of Benevento, who was beleaguered at Pazzuoli in the persecution of Diocletian. His body was brought to Naples, where a beautiful chapel is erected to his memory in the cathedral. Whence renders his name remarkable, is a pretended miracle exhibited yearly by the priests, who say they have the faint's real blood enclosed in a phial, which is either liquid or concealed at the pleasure of the devout gentlemen. This wretched mummary is always practised when Mount Vesuvius flings visions of a convulsion, and the people believe that the influence of Januarius will prevent an earthquake. This pious fraud will scarcely live beyond the changes which are now taking place in Italy. Moreri. Addisdon's Travels.

JANUARIUS, ST., Order of, was instituted July 2, 1738, by the Infant Don Carlos, then king of Jeusalem and the two Sicilies, and afterwards king of Spain, who was grand master of the order, and the honour of which devolved on the king of the two Sicilies. The enjoin of the order is a star of eight points, enamelled white, edged with gold: in the centre is represented a bishop, with half his body in clouds: on the reverse is a book, on which are two vials red, surmounted with two palms, all enamelled in proper colours. The collar of the order is of gold, composed of chains, banners, mitres, rosettes, &c. The badge in ordinary days is worn pendant to a broad deep-blue ribbon.

JANUARIUS'S Blood. See Religious use of Blood. The head of this faint is occasionally carried in procession at Naples, in order to fortify the affection of Vesuvius.

JANUARY, the name of the first month of the year, according to the computation now used in the West.

The word is derived from the Latin Januarius, a name given it by the Romans, from Janus, one of their divinities, to whom they attributed two faces; because on the one side the first of January looked towards the new year; and, on the other, towards the old one. The word Januar
arius may also be derived from janua, gate; in regard to this month being the first, which is, as it were, the gate of the year.

January and February were introduced into the year by Numa Pomphilus; Romulus's year beginning in the month of March.

The Christians heretofore failed on the first day of January, by way of opposition to the epilepticion of the heathens, who, in honour of Janus, observed this day with fealtlings, dancing, multuratures, &c.

JANUB, in Geography, a town of Peria, in the province of Kerman; 126 miles E. of Kabis.

JANVILLE, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Chartres, 21 miles S.E. of it. The place contains 1803, and the canton 10,468 inhabitants, on a territory of 290 kilometres in 23 communes.

JANUM, in Scripture Geography, a city of Judah, mentioned Jos. xv. 53.

JANUA, in Geography, a town of Hindoostan, in Goondwanah; 20 miles N. of Chanda.

JANUS, in Mythology, a divinity of the Romans, who, as it is said, had the custody and care of their gates (Janua). As to the origin of this deity, ancient authors are not agreed; but the most general opinion is, that he was not a native of Italy, but that he came thither from Perbebia in Thebais, where, being a descendant from Dec了不少, as fabulous history reports, he was originally fettered. Rycckius dates the arrival of Janus with his colony in Italy in the 146th year before the taking of Troy; but as Theoplyphus of Antioch affures us, that Chronos, called by the Latins Saturn, and who was received by Janus into Italy, lived 321 years before the taking of Troy, there must have been 321 years before an age and a half between him and Janus. Hence we should be led to conclude, either that Saturn never came into Italy, or that he arrived there long before the time of Janus. Antiquity, however, ascribes co-existence to these princes; therefore we must suppose that there was another Saturn, contemporary with Janus, whose native name was Stercus, the father of Picus; and that being deified by Janus, he was, after his apotheosis, denominated Saturn. To this purpose we learn from Aurelius Victor, that Janus, having landed in Italy, and made various conquests, took possession of a mountain, and there built a city which he called after his own name, "Janiculum." In the time of his reign, Saturn, banished from his own country, landed also in Italy; where Janus kindly received him, and made him his associate in the empire. Saturn built a fortress near Janiculum and called it "Saturnia." The part of the country which Janus first occupied was Latium; and it is said that the inhabitants, before the arrival of this prince, led a savage life, without laws and almost without religion; and that he softened the ferocity of their manners, brought them to live together in cities and villages, gave them laws, and taught his subjects to enjoy under his reign a happiness which they had never known before; accordingly this period was denominated the golden age. From this change of condition, produced by the counsels and influence of Janus, the inhabitants rendered him divine honours; and he was regarded, not as one of the great gods, but as one of the Indigetes. To him also, as we learn from Macrobius, all the sacrifices or to the houses were consecrated; because, according to the Mythologists, every family in the time of Janus was distinguished by religion and fatty.

The origin of this custom is not certainly known. Accordingly when the confuls, appointed to command the army, was ready to set out, he went to this temple, attended by the senates, the chief citizens, and his soldiers in their military dress, and opened its gates. The new confuls took possession of their offices in this temple; whence they were laid to open the year. See Macrobi. Saturn. lib. i. cap. 9; and Virgil, Æn. lib. vii. v. 601, 622.
This temple was in the Roman forum, and Procopius says, that in his time the remains of it were still to be seen there over against the capitol, with a little niche of bronzes, in which was its statue.

There was a second temple of Janus, built by Ca. Duillius, in the Forum Olitorium, or herb-market, after the first Carthaginian war; and this, being fallen into decay, was restored by the emperor Tiberius, according to Tacitus, Ann. 1. 2.

A third temple of Janus, called "Templum Jandi Augusti," was situated in the Velabrum, a little valley, on one side of the Forum Boarium, or ox-market, between the capitol and mount Aventine. It was a square building of the Ionic order, and entirely of marble. Some say, that it was built by Numa, and repaired by Augustus; but others dispute its high antiquity. This was the temple of Janus quadribriones, or the four-faced Janus; and owed its origin as well as its name, to the following accident, according to Servius. The Romans, he says, after the taking of Faleria in Tuscany, having met with a statue of Janus that had four faces, were driven to have such a one as Romulus and to honour him the more, they built for him a temple with four fronts, each having twelve niches in it, with a great gate, which denoted the four seasons, and the twelve months of the year. Varro says there were also twelve altars in this temple, dedicated to Janus, each of which represented a month of the year.

JANUSUS, in Ancient Geography, a town of Syria, situated on the coast, between both the Sidon and Idumea lakes, according to Herodotus, who adds, that it is at the distance of three days' journey from mount Cacus.

JANZE, in Geography, a town of Frace, in the department of the Isle and Vilaine, and chief place of a canton, in the district of Rennes; 5 miles S. of Château-Giron. The place contains 3,512, and the canton 13,815 inhabitants, on a territory of 17,471 square miles, in 6 communes.

JAO, a town of Japan, in the island of Niphon; 35 miles S. of Meaco.

JAOURHORISI, a town of Afsitic Turkey, in the province of Diarbekir; 63 miles W. of Nisibis.

JAP. Among Hindoo mystics great merit is ascribed to abstraction, or silent contemplation of the attributes of the deity. This is effayed by enthusiastic individuals most pervertingly; to the length, as it is pretended, of complete absorption of all intellectual power, by a sort of spiritual union with the attribute or deity thus propitiated. Another species of abstract devotion is called Tapan (which see); but this includes also penance and austerity; whereas jap, we believe, is confined to abstraction, induced by silent and intense contemplation. To promote this, the aspirant sometimes continues with closed eyes, or with his eyes fixed on the tip of his nose. Rofaries are also used in the commencement of this species of devotion, or by those who intend only a short exercise of it. Such rofaries are called japnayi.

JAPACANI, in Ornithology, a species of Oriolus; which see.

JAPAN, in Geography, a kingdom or empire, consisting of several islands, and situated near the eastern extremity of Asia, between the 30th and 41st degree of N. latitude, and the 131st and 143rd degree of E. longitude. The coast of Japan is, according to Kempfer, the most dangerous in the whole world; and captain Gore found strong and rapid currents setting along the eastern coast, which he has particularly described. (See Cook's Third Voyage, vol. iii, p. 406.) This empire has been called by Marco Polo Zipangri, or Zipang; by the inhabitants themselves, Niphon, Nipon, or Nison; and by the Chinese Sippon, and Jepuen. The principal islands of which it consists, omitting several of a smaller size, are, towards the S.W., Kyfia (called also Ximo, Saikok), or the western country, and Sikok or Xicogo; N.E. of these Nipon or Niphon, the most important; and N. of Niphon, Jefio, Jefio, or Chicha. The Japanese islands probably derive their original population from the Chinese by way of Corea. Conse uence, their languages are radically distinct. It appears from Kempfer's account, that the Japanese themselves acknowledge their government and civilization to have been derived from China. This author distinguishes three epochs in their history; the fabulous, the doubtful, and the certain. The latter period commences with the hereditary succession of the ecclesiastical emperors, from the year 660 before the Christian era, and extends to the year of Christ 1259, during which 167 princes of the same lineage governed Japan. At the last period the feudal princes assumed the supreme authority. The several reigns are generally pacific, though at distant intervals the Mandhirs and Coreans occasionally invaded Japan, but were always defeated by the valour of the Japanese. An attempt was also made by the emperor of China, and the Moguls, to make a grand invasion of Japan, after having conquered China about fourteen years before. But the formidable fleet, consisting, according to exaggerated reports, of 4,000 small vessels, which contained an army of 240,000 men, was dispersed by a furious tempest, which the Japanese devoutly ascribed to the gods, their protectors. The religion of the Japanese is Polytheism, intermixed with an acknowledgment of a supreme creator. Their two principal feets are those of "Sinto" and of "Budido." The first acknowledges a supreme being, far superior to the worship of man, and they therefore adore the inferior deities as mediators. They believe that the souls of the virtuous have a place allotted them immediately under heaven, while those of the wicked wander in the air till they expiate their offences. They abstain from animal food, defile bloodshed, and will not touch any dead body. Tumburk further says, that though it is unnecessary on any occasion to pray to the gods, whom they call "Sin," or "Kami," because they know all things, they have both temples and certain festal holidays. These temples consist of several apartments and galleries, with windows and doors in front, which may be taken away and replaced at pleasure, according to the custom of the country. The floors are covered with straw mats, and the roofs overhang an elevated path, in which people walk around the temples. In these temples there is no visible idol or image for representing the supreme invisible being; but they sometimes keep a little image in a box, which represents some inferior divinity to whom the temple is consecrated. In the centre of the temple is often placed a large mirror of well polished metal, destined to remind those that come to worship, that in like manner as their personal blemishes are faithfully portrayed in the mirror, so do the secret blemishes and evil qualities of their hearts lie open and exposed to the all-searching eyes of the immortal gods. The priests are either secular or monastic. Their festivals and modes of worship are cheerful and gay, for they regard the gods as beings who solely delight in dispelling happiness. The first day of the month is always kept as a holiday; so is the first day of the year; and besides these they have three or four other grand festivals. There are also several orders of monks and nuns. The feast of "Buddido," which is the same with that of "Boodh," the "Bodhi" of the Hindus, or the "Boodh," which was imported from Hindoostan; and passing through China and Corea, its tenets have been blended with foreign maxims; but the doctrine of
of the metempychoicmains remaining; wicked souls being sup-
poused to migrate into the bodies of animals, till they have un-
gone a due purification.

The doctrine of their philosophers and moralists, called
"Shuto," resembles the Epicurean, though it is blended with
the tenet of Confucius, that the purest source of pleasure is a
virtuous life. This fact admits a soul of the world; but it
does not allow infinite gods, temples, or religious forms.

Soon after this country was discovered by the Portuguese,
missionaries from the Jesuits arrived in 1549, and they and
their successors continued to diffuse their doctrine till 1638,
when 37,000 Chrillians were massacred. Before this period
various persecutions had occurred; and in 1590 upwards of
20,000 are said to have perished. The Christian faith has,
indeed, been so perverted and disgraced by the pride and
arvice of the Portuguese, and the vain ambition of the
Jesuits, that since the above-mentioned memorable epoch,
Christianity has been held in the greatest detestation; and
the crofs, with its other symbols, are annually trampled under
foot; nevertheless, it is a fable that the Dutch are constrained
to join in this ceremony.

As to the government of Japan, the "Kubo," or secular
emperor, is now the sole monarch; but till near the close of
the 17th century the "Dairi," pontiffs or spiritual mon-
hed, held the supreme authority. The secular prince, in
concurrency with the Dairi, confers two honorary ranks, cor-
responding to those of our noblemen and knights. The
Dairi resides at Nargo, and his court remains, though not in
its former splendour. Each province is governed by a re-
dent prince, who is responsible to the emperor for his ad-
ministration. The emperor derives his chief revenue from
his own estate, consisting of five inferior provinces and some
detached towns. Each prince enjoys the revenues of his fief,
with which he supports his court and military force, repairs
the roads, and defrays every civil expense. The princes of
the first dignity are styled "Daimio," and those of inferior
rank "Sionio;" and they are generally hereditary. Upon
the whole we may observe, that the constitution of Japan
consists of an absolute hereditary monarchy, supported by a
number of absolute hereditary princes; whose jealousy of
each other's power compels with domestic pledges to ren-
der them subservient to the supreme head. The laws, ac-
cording to Thuynberg, are few, but rigidly and impartially
enforced. The code is written in large letters, and polled up
in every town and village. Death is the common punishment
of crimes, but sentence of death must be signed by the pri-
cy council at Jeddo. Parents and relations are answerable for
the crimes of those whose moral education they ought to have
superintended. The police is excellent; each town having a
chief magistrate, and each street a commissary, elected by
the inhabitants to guard property and tranquillity. Two
inhabitants alternately patrol the streets by night to prevent
fire.

The population of the Japanese empire, which is very
considerable, is not easily ascertained. Its regular military
force is estimated at about half a million, the infantry being
468,000, and the cavalry 58,000, and if the army be
doubled, the population may be counted at a million; but
it may be more exactly deduced from supposing that it is
equal to that of China; and as the former country is only
about one-tenth of the size of the latter, the whole
number of people will be about 32,000,000. The character
of the people is singularly brave and resolute. The Navy
scarcely deferves notice. The Japanese vessels are open at
the stern, so that they cannot bear a boisterous sea. Span-
berg, however, describes two kinds of vessels, one answering
to Kempfer's, and another, which he calls busses, and in
which, he says, they make their voyages to the neighbouring
islands. As Japan consists of islands, and is destitute of a
navy, it can have no external political importance; but it
has little to apprehend from any neighbouring power. The
revenues of the empire may be figured at 28,340,000. ster-
ling, besides the provinces and cities that are immediately sub-
ject to the emperor, who, besides these, has a considerable
tribute in gold and silver, deposited in chests of 1000 taels,
each being equal in value to a Dutch six-dollar, or about
41. 4s. English money.

The Japanese, with respect to their persons, are well
made, active, easy in their motions, and having flat limbs,
though less strong and athletic than the other northern inhab-
itants of Europe. The men are of a middling size, with
yellowish complexions, though some few, especially the
women, are almost white. Their narrow eyes, very much
funk in the head, and high eye-brows, resemble those of the
Chinife and Tartars. The eyes incline to black, and the
eye-balls form in the great angle of the eye a deep furrow,
which discriminates them from other nations. Their heads
are generally large, their noses, though not flat, rather thick
and short; their hair black, thick, and shining in con-
sequence of the use of oils. The mode of the men's head-
dress is peculiar; the middle part of their heads, from the for-
head very far back, is close shaven. The hair remaining round
the temples and apex of the neck is turned up and tied on the
side, and fastened with a white thread and bent backwards.
The women prefer all their hair, and, drawing it together on the top of the head, roll it round a hoop, and fastening it down with pins, to which ornaments are fixed, draw out the sides till they appear
like little wings, behind which they flick a curl. Physicians
and priests shave the head entirely, and are thus distinguished
from the rest of the people. The fashion of their clothes
has undergone little alteration from remote antiquity. They
confit of one or more loose goaves, tied about the middle
with a fath; those of the woman being much longer than the
men's; in summer they are very thin, and in winter quilted
with silk or cotton wadding. Perfons of rank have them
made of silk; and those of the lower clafs of cotton stuff.
Those of the women are ornamented with gold and silver
flowers woven into the stuff. At the breadth these goaves are
opened, and they have wide sleeves, which ferve as pockets.
Some have drawers; but their legs are naked. They wear
sandals of rice-draw; in winter they have socks of linen,
and in rainy or dirty weather wooden shoes. They never
cover their heads except when they travel, and then use co-
nical caps made of straw; for defending themselves against
the rain or sun, they use fans or umbrellas. In their fah:
they falk the fafe, fan, and to bacco-pipe. Their houfes
are built with upright posts, croffed and wattled with bamboo,
platted within and without, and white-walled. They are
generally of two flories; the roofs are covered with large
and heavy pantiles: the floors are covered with planks, on
which they lay mats, filled with straw. The whole houfe
consists of one large room, divided by wooden partitions;
and their windows are frames of wood, separated into
squares, filled up with thin white paper, and sufficiently trans-
parent to answer the purpose of glass. In their rooms they
have no kind of furniture; not even beds. Their custom is
to lie down upon their heels on the mats, which are always
soft and clean. Their vihuals are served up on a low board,
raised a few inches from the floor, and only one dish at a
time. They have mirrors, made of a compound metal, which
they use only at their toilets. In the severity of
winter, they are obliged to warm their houfes from
November to March; but they have neither fire-places nor
fires:
JAPAN.

flowers; instead of these they use copper-pots standing upon legs; these are lined on the inside with loam, on which are laid ashes, and upon which the leaves of tobacco are prepared as not to render its flavor dangerous. The use of tobacco, probably first introduced by the Portugueze, is very common among both sexes, both old and young; and the smoke is blown out through the noztrils. The first compliment offered to a stranger in their houses is a dish of tea and a pipe of tobacco. Their pipes have mouth-pieces and bowls of brass, or white copper. The hollow of the bowl is so small as scarcely to contain an ordinary pea; and the tobacco is cut as fine as a hair about a finger’s length; and is rolled up in small balls like pills, to fit the small hollow in the bowl of the pipe. Every house has a bath, which, as the people are very cleanly, is daily used by the whole family. You seldom meet a man, who has not his distinguishing mark imprinted on the sleeves and back of his clothes, in the same colour in which the pattern is printed. Their usage of names differs from that of all other nations. The family name is never made use of, except in fixing solemn contracts, and the particular names by which individuals are distinguished in conversation varies according to the age or situation of the person who makes use of it; so that in some cafes, the same person, in his life-time, is known by five or six different names. They reckon their age by even years, but not regarding whether they were born at the beginning or the end of a year. In general, the Japanese are a highly civilized people, displaying great diversity of character; but their virtues far outweigh their vices. Obedience to parents and respect to superiors form the characteristic of this nation. Their fatuities, or mutual intercourse among equals, are distinguished by civility and politeness; and to these children are early accustomed by the example of their parents. Their pride is useful, as it prevents their stooping to the mean tricks of the maritime Chinese. Though polygamy be allowed, they acknowledge only one wife; the others being merely concubines. Marriages are conducted by the parents or relations; and domestic tranquility is injured by the wife’s being under the absolute disposal of her husband, the laws allowing her no kind of claim if she incurs his displeasure. Examples of infidelity are rare. In case of separation, the wife is condemned to the ignominy of having her head always shaved. The marriage ceremony is always performed before an altar, by the bride’s lighting a torch, from which the bridegroom kindness another. The bodies of the distinguished dead continue to be burned, while others are buried. Periodical visits are paid to the tombs, besides the festival of lamhorns, held as in China, in honour of the departed. As to food and sauces those of the Japanese are very various. Their general drink is “Sariki,” or beer made of rice, which last article supplies the place of bread. They use many kinds of vegetables and fruits. Tea is universally used; but wine and spirituous liquors are unknown. The Japanese festivals, games, and theatrical amusements, equal those of the most civilized nations. Dancing girls are common; and the introduction of boys indicates an abominable propensity here, as in China, neither repressed a crime nor a singularity.

The language of the Japanese, of which Thunberg has published a curious vocabulary, seems to have little connection with the monosyllabic speech of the Chinese. In sciences and literature the Japanese are not inferior to few of the oriental nations. In domestic economy, deemed here a science, and also in the history of his country, every person in Japan excels. Astronomy is cultivated, but to no very important and useful purpose. The art of printing is of ancient usage, but they use blocks and not movable types, and imprefs only one side of the paper. They are excellent workmen in iron and copper; and yield to none in manufacture of silk and cotton, and in the art of varnishing wood. Glass is common, and they make telescopes. The porcelain is deemed superior to that of China. Their celebrated varnish is obtained from the “rhiz vernix.” They have many varieties procured from the bark of a species of mulberry tree; and their woods display incomparable skill. They have many schools, in which the children are taught to read and write; and their education is accomplished without personal chafiment, while courage is inftilled by the repetition of songs in praise of deceased heroes.

Although the mountains of Japan prevent the formation of canals, their roads are kept in excellent order, and the proximity of the sea renders inland navigation almost unnecessary. Their inland commerce, being free from imports, is very considerable; and their external commerce, though confined to the Dutch and Chinese, is extensive. The harbours are crowded with large and small vessels; the high roads with various goods; and the shops are well repolished. Large fairs are held in different places, to which a great multitude of people resort. Their trade with China is the most important, and consists of raw silk, sugar, tartarine, drugs, &c. while the exports are copper in bars, lacquer ware, &c. The Dutch export copper and raw camphire, for which they give in return sugar, ripe cloves, Japan wood, ivory, tin, lead, tortoise-shell, chintzes, and a few other trifles. In their intercourse both with the Dutch and Chinese, they trade with companies of privileged merchants. As the Dutch company have not been accustomed to pay duty in Japan, either on their exports or imports, they used to send an annual present to the court, consisting of cloth, chintzes, fascotas, cottons, fluffs, and trinkets. Thunberg represents the profits of the Dutch trade as very inconsiderable, so that the company employed only two ships. The Japanese coin is of a remarkable form: the gold being called “Kobango,” the silver, called “Kodama,” sometimes represents “Daikok,” the god of riches, fitting upon two barrels of rice, with a hammer in his right hand, and a fack at his left. The “Sen” of copper or iron, are ftrung like the Chinese pieces of similar value.

The climate of Japan is variable. In summer the heat is violent, and if it were not moderated by frequent rains, would be intolerable. The cold in winter is severe. The fall of rain commences at Midsummer, and to these Japan owes its fertility, and also its high state of population. Thunder is not unfrequent: tempests, hurricanes, and earthquakes, are very common. From Thunberg’s thermometrical observations it appears that the greatest degree of heat at Nagasaki, was 98° in August, and the severe cold in January 35°. The face of the country presents, besides some extensive plains, more generally mountains, hills, and valleys; the coast being mostly rocky and precipitous, and invested with a turbulent sea. It is also diversified with rivers and rivulets, and many species of vegetation. The soil, though barren, is rendered productive by fertilizing showers and manure, and by the operations of agricultural industry. Agriculture, as Thunberg informs us, is here well understood, and the whole country, even to the tops of the hills, is cultivated. Free from all feudal and ecclesiatical impediments, the farmer applies himself to the culture of the soil with diligence and vigour. Here are no commons, and it is a singular circumstance, that if any portion be left uncultivated, it may be seized by a more industrious neighbour. The Japanese mode of marrining is to form a mixture of all kinds of excrements, with kitchen refuse, which it carried in pits into the field, and poured
pared with a ladle upon the plants, when they have attained the height of about 6 inches, so that they thus instantly receive the whole benefit. They are also very attentive to weeding. The sides of the hills are cultivated by means of stone walls, supporting broad plats of rice or other roots. Rice is the chief grain: buckwheat, rye, barley, and wheat being little used. A kind of potato (convolvulus edulis) is abundant with several sorts of beans and peas, turnips, cabbages, &c. From the feed of a kind of cabbage lamp oil is expressed; and several plants are cultivated for dyeing; with the cotton shrubs, and mulberry trees for the food of silk-worms. The varnish and camphire trees, the vine, the cedar, the tea tree, and the bamboo reed, not only grow wild, but are planted for numerous uses.

The principal rivers of Japan are the Nagfka, Jedogura, Ojinguwa, Fujigawa, Sakigawa, Jodo or Yodo, Ujina or Ojina, Oomi, and Ake. One of the chief lakes is that of Ohiza, said to be 50 Japanese leagues in length, each about an hour's journey on horseback, but of inconceivable breadth. It flows two rivers; and near it is the delightful mountain of Jefan, which is esteemed sacred, and is said to contain no less than 3000 temples. The principal Japanese mountain is that of Fuji, covered with snow almost throughout the year. The Hakone are in the same quarter, surrounding a small lake of the same name. Many of the mountains are covered with wood. There are several volcanoes; and they generally abound with evergreen trees, and crystalline springs. Near Firdako there is a volcanic brands; and in the province of Figo there is a volcano, which constantly emits flames, and another, which was formerly a coal-mine, in the province of Tikofer.

In the whole empire of Japan there are neither sheep nor goats; and, in general, there are but few quadrupeds. The food of the Japanese consists almost entirely of fish and fowl, with vegetables. Some few dogs are kept from motives of superstition; and cats are favourites of the ladies. Hens and common ducks are domiciliated for the sake of their eggs. The mineralogy of Japan has been particularly slated by Thunberg: from whom we learn, that gold and silver are to be found in abundance; copper is also quite common: but iron is scarcer than any other metal in this country. Of that which is found they manufacture feynmarts, arms, foellons, knives, and other necessary implements. Amber, brimstone, pitch-oil, agate, albeto, porcelain clay, flesh-coloured fletish, nacre, and white marble are enumerated among the productions of Japan. Many small islands are dependents on this empire, particularly in the S. and E.; among which is Fatufiro, the place of exile for the grandees. For other particulars we refer to Kämpfer, Thunberg, Phil. Trans. vol. 1. and Pinkerton's Geography, vol. ii.

JAPAN Earth. (See CATECHU.) The extract prepared in the manner, flated under that article, is much ueed by the natives of Hindoostan in dyeing and painting chintz and other cloths; combined with the vitricol salts, a black colour is produced: mixed with oil they paint the beams and walls of houses to prefer them, and to defend them from the destructive white ants; and it is sometimes mixed with their wall-plaster. The extract is used only medicinally as a cooling medicine, and when too profusely used, it is said to be a destroyer of venereal pleasures. It is also given at the rate of two ounces a day to tame vicious horses. This extract is likewise a principal ingredient in one of their ointments, of great repute, composed of blue vitriol, four drams; Japan earth, four ounces; alum, nine drams; white reef, four ounces; which are reduced to a fine powder, and mixed with the hand, adding of olive oil ten ounces, and water sufficient to bring the mass to the proper consistence of an ointment; this ointment is used in every sore from a fresh wound to a venereal ulcer. Med. Obs. and Inq. vol. v. art. 16. The antieptic quality of catechu appears from the experiments of Sir John Pringle.

The London college formerly directed Japan earth to be made into troches by beating it with an equal weight of gum arabic, and four times the weight of both, of figur of roes, and a sufficient quantity of water; but the college of Edinburgh ordered one part of the Japan earth, four of gum tragacanth, and twenty-two of fine sugar, with roe-water. The cadura Japanica, or liquid Catechu, is prepared by dissolving, for fourteen days, three ounces of the extract of catechu, and two of cinnamon bark bruised, in a quart of proof spirit; and this tincture may be given in doses of two or three spoonfuls. The infusion of catechu is prepared by macerating for an hour in a covered vessel 24 drams of the extract, half a dram of bruised cinnamon bark, in half a pint of boiling water. This is one of the best forms in which catechu can be exhibited, as it is thus at once freed from its impurities, and improved by the addition of the aromatic. For the method of preparing Japanese confection, see CONFECTION. Japan earth dissolved in water is of a dull brown colour, a little inclined to red. It is sometimes used in water-painting, where it has a good effect; but its gummy texture renders its use improper in oil.

JAPANERS GILDING. See GILDING.

JAPANNING, the art of varnishing, and drawing figures on wood, &c. after the same manner as the workmen do who are natives of Japan.

The varnish made and used in China and Japan is composed of turpentine, and a curious fort of oil they have. This they mix and boil up to a proper consistence, and this never causes any swelling in the hands or face of the people who use it. The swellings in these parts, which often happen to those who work the lacquered ware, and sometimes to those who only pass by the shops of these people, is from the lack, and not the varnish. This lack is the sap or juice of a tree, which runs slowly out on cutting the lower part of the trunk of the tree, and is received in pots set on purpose under the incisions. The juice, as it flows from the tree, is of the colour and consistence of cream; and as it comes in contact with the external air, its surface becomes black. As they only use it when black, their method of preparing it is to let it out in the open air, in large flat bowls, in which it looks all surface; but that the whole may be of the same uniform colour, they continually stir it for twenty-four hours together, with a smooth piece of iron. By this means the whole becomes thicker than it was before, and of a fine deep black. When it is in this state, they powder some burnt bunches of trees, and mix them thoroughly with it; and then spreading it thin over any board which they intend to Japan, it is soon dried in the sun, and is then absolutely harder than the board it is laid on. When this is thoroughly dry, they polish it over with a smooth stone and water, till it is as smooth as glass; and then dipping it very dry, they lay on the varnish made of oil and turpentine, and boiled to a proper consistence for this kind of work.

If the work is to be of any other colour than black, that colour is to be mixed with the varnish, and then the whole spread on very thinly and evenly; for on this laying it on depends the principal art of varnishing. When there are to be figures in gold and silver, these must be traced out with a pencil in the varnish over the rest of the work; and when this varnish is almost dry, the leaf-gold or leaf-silver is
to be laid on, and polished afterwards with any smooth
finish
The substances which admit of being japanned are al-
mold those of every kind that are dry, and not too flex-
ible; as wood, metals, leather, and paper prepared. Wood
and metals require no other preparation, except that of
cleaning their surfaces, and rendering them perfectly even.
But leather should be securely strained either on frames or
on boards; and paper should be treated in the same manner,
and have a previous strong coat of some kind of size; but
it is rarely made the subject of japanning, till it is converted
into paper mâché, or wrought, by other means, into an
inflexible form. One principal variation in the manner of
japanning is the using or omitting any priming or under-
coat on the work to be japanned. In the older practice,
such priming was always used; and is at present retained in
the French manner of japanning coaches and fan-window-boxes
of the paper mâché. But in the Birmingham manufacture it
has always been rejected. The advantages attending the
use of such priming are, that it makes a saving in the quan-
tity of varnish necessary to be used, and that it helps to form,
by means of rubbing and water-polishing, an even surface
for the varnish. However, when an under-coat of size is
used, the japan coats of varnish and colour will be always
liable to crack and peel off, and are less durable than thoile
which are formed without such priming. This difference is
obscurely in comparing the work of the Paris and Birmin-
gham fan-window-boxes.

The laying in of the colours in varnish or oil instead of
gum-water, is another variation from the method of japau-
ning formerly practiced. But if the colours are tempered
with the strongest ingenous size and honey, instead of gum-
water, and laid on very flat and even, the work will not
be much inferior in appearance to that done by the other
method, and will last as long as the common old japan
work, the best kinds of the true Japan excepted. The
proper japan grounds are either such as are formed by the
varnish and colour, where the whole is to remain of some
form of colour; or by the varnish, either coloured, or without
colour, on which some painting, or other decoration, is af-
fterwards to be laid. The priming, or under-coat, which is
sometimes used in japanning, is of the same nature with
that called clear-coating, practiced by the house-painters;
and confides in laying on and drying in the most even manner
a composition of size, flour, and whitew. The common size,
(fine Sizes,) has been generally used; but in nicer works,
the gellers or the parchment size, improved by adding a
third of ingenious, will be preferable. The work should
be prepared for this priming, by being well smoothed with
fine-skim, or the glash-flavor; and by being brushed over
once or twice with hot size diluted, when it is of the com-
mon strength, with two-thirds of water. The priming,
formed of a size whole consistence is between that of the
common kind and glue, mixed with as much whitew as will
give it a sufficient body of colour to hide the surface on
which it is laid, should be laid on evenly with a brush. Two
coats of this priming will generally be sufficient; but if,
on trial with a fine wet rag, it will not receive a proper
water-polish, another coat or more must be given it. And
after the last coat but one is dry, the work should be smooth-
ed by rubbing it with the Dutch rufles. When the last coat
is dry, the water-polish should be given, by passing over ever-
part of it with a fine rag, a little moistened, till the whole
appears perfectly plain and even. The work is then ready
to receive the painting or coloured varnish.

When wood or leather is to be japanned, without priming,
it may be prepared by laying on two or three coats of coarse

varnish, made by dissolving two ounces of feed-lac, and as
much rosin, in one pint of rectified spirit of wine; and
then the proper japan-ground must be laid on. As metals
never require to be under-coated with whitew, they must
generally be treated in the same manner as wood or leather.

For white japan grounds.—Prepare a white varnish, by
working and grinding flake white, or white lead, with a
sixth part of its weight of flour, and drying the mixture;
then temper it into a consistence fit for spreading with ma-
fic varnish, (see VARNISH,) or compound it with gum
anime; lay this on the body to be japanned, previously pre-
pared with or without the under-coat of whitew; and var-
nish it over with five or six coats of the following varnish,
formed by dissolving two ounces of the clearleaf and whitest
grains of feed-lac, and three ounces of gum anime, pulver-
ized, in about a quart of spirit of wine, and straining off
the clear varnish.

A very good varnish, free from britteness, may be ob-
tained by dissolving as much gum anime as the oil will take
in old nut or poppy oil, boiled gently when the gum is put
into it. The ground of white colour may be laid on this
varnish, and then a coat or two of it may be put over the
ground; but it must be well diluted with oil of turpentine
when it is used.

Blue japan grounds may be formed of bright Prussian blue;
or of verditer glazed over with Prussian blue, or blue.
The colour may be bell mixed with shell-lac varnish, and brought
to a polishing flat by five or six coats of varnish of feed-lac.
But when a bright blue is required, and a less degree of hard-
ness can be dispensed with, the method before directed, in
the case of white grounds, must be pursued.

Red japan grounds.—For a scarlet ground, vermilion may
be used; but this is less beautiful than the crimson pro-
duced by glazing it over with Carmine or fine lake, or rose-
pink. For a very bright crimson instead of glazing with
carmine, the Indian lake, called safflower, should be used,
dissolved in the spirit of which the varnish is compounded.
But in this case, instead of glazing with the shell-lac var-
nish, the upper or polishing coats need only be used; which
will render this a cheaper method than the using of carmine.
If the highest degree of brightness be required, the white
varnishes must be used.

Yellow grounds.—For bright yellow grounds, king’s
yellow, or rupeth mineral should be used, either by them-
sefes, or mixed with fine Dutch pink. The effect may be
stillmore heightened by dissolving powdered turmeric root
in the spirit of wine, of which the upper or polishing coat
is made; which spirit of wine must be strained off from the
dregs, before the feed-lac be added to it for forming the
varnish.

Yellow grounds may likewise be formed of the Dutch
pink only.

Green japan grounds may be produced by mixing king’s
yellow and bright Prussian blue; or rupeth mineral and
Prussian blue. A cheap, but fouler kind may be had from
verdigris with a little of the fore-mentioned yellows, or
Dutch pink. But if a very bright green be wanted, the
crystals of verdigris, called diluipred verdigris, should be used,
and their effect will be heightened by laying them on a
ground of leaf-gold. Any of these may be used with
good feed-lac varnish, but will be brighter with the white
varnish.

Orange-coloured japan grounds may be formed by mixing
vermilion or red lead with king’s yellow, or Dutch pink;
or orange lake, or red orpiment will make a brighter orange
ground than can be produced by any mixture.

Purple japan grounds may be produced by the mixture of

Vol. XVIII.
The S. For long by See ofove, for this his Medes lire, probably Magog dry, for which it should be used instead of the tripoli. For gilding of Japan work, see Japanners Gilding. Handmaid to the Arts, vol. ii. p. 497, &c.

JAPARA, in Geography, a sea-port town of the island of Java, situated on a peninsula on the N. coast; the harbour is formed by a river of the same name, and is capable of receiving a great number of ships. The Dutch have a resident here for the purchase of timber, cotton, rice, and indigo. About four miles S. from this town is the ancient city of Japara, once the capital of a kingdom. Not far from this is an old and ruinous Moorish temple of stone, with beautiful sculpture of imagery and foliage; this temple is more than 300 years old. S. lat. 6° 28ʹ. E. long. 110° 54ʹ.

JAPANESE, a town of Africa, in the kingdom of Jagra.

JAPHA, in Ancient Geography, a city of Galltee, near Jutapata, according to Josephus; probably the same with Japhia (Josh. xix. 12) belonging to the tribe of Zebulun. It was strongly fortified; and was belied and taken by Trajan, the father of the emperor of this name, who massacred all the inhabitants who were capable of bearing arms, and made slaves of the women and children, A.D. 67. See JOPPA.

JAPETH, in Scripture Biography, the eldest son of Noah, who was born in the 500th year of this patriarch, and who had seven sons, viz. Gomer, Magog, Madai, Javan, Tubal, Meshech, and Tirah, who “peopled the isles of the Gentiles, and settled in different countries, each according to his language, family, and people.” (Gen. x. 5.) By the “isles of the Gentiles,” the Hebrews understood the isles of the Mediterranean, and other countries whither they could go by sea only, as Spain, Gaul, Italy, Greece, and Asia Minor; and with respect to these seven sons of Japheth it is very generally supposed that Gomer was the father of the Cimbrii, or Cimmerians; Magog of the Scy- thians; Madai of the Macedonians or Medes; Javan of the Ionians and Greeks; Tubal of the Libyans; Meshech of the Muscovites or Russians; and Tirah of the Thracians. From the LXX, Eusebius, the Alexandrian Chronicle, and Aultin, we learn that Japheth had an eighth son called Eliza.

The portion of Japheth was Europe and part of Asia, whose descendants possessed all Europe, all the islands in the Mediterranean, the whole of Asia Minor, and the northern parts of Asia. Noah, in his benediction of Japheth, prophesied concerning him (Gen. ix. 27), “God shall enlarge Japheth; and he shall dwell in the tents of Shem; and Canaan shall be his servant.” This prediction was accomplished when the Greeks and Romans, who were descendants of Japheth, not only subdued Syria and Palestine, but also purged and conquered all the Canaanites as were anywhere else, viz., e.g., the Tyrians and Carthaginians, the conquerors of whom were received by Alexander and the Greeks, and the latter by Scipio and the Romans. In the original of the prediction, “God shall enlarge Japheth,” there is a manifest allusion to his name, which signifies enlargement. This was fulfilled both with regard to the territory and children of Japheth. The territories of Japheth’s posterity were very large; for besides all Europe, extensive as it is, they possessed the Lesser Asia, Media, part of Armenia, Iberia, Albania, and those vall regions towards the north, which anciently the Scythians inhabited, and which now the Tartars inhabit; and it is not improbable that the
new world was peopled by some of his northern descendants, passing thither by the routes of Anian. The enlargement of Japheth also denoted a numerous progeny, as well as ample territory; for Japheth, as we have observed, had seven sons, whereas Ham had only four, and Shem only five.

In profane authors Japheth is known under the name of "Japetus," who is made by the poets father of heaven and earth; whose habitation was in Thebaly, where he became celebrated for his power and violence. Japetus married a nymph named Alia, by whom he had four sons, Herupers, Atlas, Epimetheus, and Prometheus, who were all very famous among the ancients. Neptune and Jupeter are also, among ancient mythologists, a memorial of Japheth. As Noah divided the earth between Shem, Ham, and Japheth, Saturn divided the world between his three sons, Jupiter, Pluto, and Neptune.

JAPONIC CONCEPTION. See Conception.

JAPU, in Ornithology, the name of a Brazilian bird, of the woodpecker kind, called also japonjuba. See Ornithol. Soc. Per.

JACARAIPE, in Geography, a river of Brazil, which runs into the Atlantic, S. lat. 4°.

JACQUE LAHOU, a town of Africa, on the Ivory coast; 20 miles E. of cape Labou. Also, a river of Africa, which runs into the Atlantic, N. lat. 5° 20'. W. long. 5° 5'.

JACQUEJAG, a town of Africa, on the Ivory coast; 43 miles E. of cape Labou.

JACQUEMEL, a town of Hispaniola, on the S. coast, in a bay to which it gives name. N. lat. 18° 17'.

JACQUEMEL, Cape, a cape on the S. coast of the island of Hispaniola. N. lat. 18° 14'. W. long. 73° 25'.

JACES, Cape, a cape on the coast of Chiampa, at the mouth of the river Cambodia. N. lat. 10° 40'. E. long. 107° 30'.

JACQUES, or Jaff, Cape, a cape at the western extremity of the gulf of Peria, at its entrance from the Arabian sea. This is known by a remarkable square rock, a few miles N. of it. It is a low sandy desert, with a few shrubs on it; and it is called by Le Brun cape St. James. N. lat. 25° 39'. E. long. 57° 20'.

JACQUES, St., a town of Mexico, in the province of Vera Paz.

JACQUESY, a town on the N. coast of Hispaniola; 13 miles E.S.E. of cape Francois.

JACQUET, Cape, a cape on the coast of Guzerat, in the gulf of Cutch. N. lat. 23° 25'. E. long. 69'.

JAR, or JARR, from the Spanish, jarra, or jarro, which signify the name, an earthen pot or pitcher, with a big belly, and two handles.

JAR is used for a sort of measure, or fixed quantity of divers things.—The jar of oil is from 18 to 26 gallons: the jar of green-ginger is about 100 pounds weight, of wheat 52 pounds.

JAR, a measure of Lucca oil is 25 wine-gallons = 5775 cubic inches = 33420 cubic feet = 12378 cubic yards = 168456 cubic links.

JAR, or Jair, in Chronology, one of the Hebrew months, answering to our April. It was the eighth month of the civil year, and the second of the sacred, and had only 29 days. On the 23d day of this month the Jews kept a festival in memory of the purification of the temple by Judas Macabæus. (2 Mac. xiii. 51.) On the 25th they mourn the death of Samuel.

JAR. To jar is a verb which implies to disagree, to found harshly and unutterably.

JAR, for measuring musical intervals by water. See Hyphasis.
which he had to contend with, he followed the counsel of Maimonides, looked up his collections, and applied himself
to give an illustration and commentary on the collections of
Talmudical traditions. This work being received with great
applause, he next published "Gloses on the Jerusalem and
Babylonish Talmuds;" and finally he wrote moral illustra-
tions of the bible, which were printed in the great bibles of
Venice and Basli, and were inserted in De Lyra's great
work on the sacred volume. Jarchi died at Troyes in 1180,
in the 76th year of his age. He was buried with every
mark of respect in the Jewish cemetery near that city, and
when that nation was afterwards driven out of France, they
carried his remains with them into Bohemia, and interred
them at the Ponge. He is mentioned by Reland as one of
the bell interpreters of scripture, who says, that when any
difficulties occurred to him in the Hebrew text, the illustra-
tions of rabbi Jarchi appeared more satisfactory to him
than those of the greatest critic, or any other commentator.
Moricci. Boulce.

JARDES, or JARDINES, in the Manage, are callous and
hard swellings in the hinder legs of a horse, seated on the
outside of the hough, as the spavin is on the inside. Jardons
lame a horse, unless you give the fire dexterously and be-
times. JARDIN, Karel du, in Biography, an agreeable painter
of scenes in common life, in a style partaking of Berchem's
and Wouwerman's manners united. He was born at Am-
sterdam in 1640, and was a disciple of N. Berchem; but
finished his studies in Italy, where he spent the greater part
of his life, and died at Venice in 1678.

The compositions of this master are simple. A few figures
with a horse or cattle, and a small landscape background,
generally comprise the whole; and they are most usual
on a small scale. His colour is rich and bright; and fre-
quently very agreeable; expressing happily the glow and
effect of sun-thine; or the duller light of a lowering day.
The defect of his works is somewhat of hardnefs in the
touch, which, however, is very delicate and neat; and has
great spirit and brilliancy.

JARDINES, Los, in Geography, small islaands and rocks
near the south coast of Cuba. N. lat. 21° 18'. W. long.
84° 50'.

JARDINS, Mary Catherine des, in Biography, a celebreated novel writer, was born at Aleçon in 1640. An
early adventure in gallantry having obliged her to quit her
native town, she went to Paris in her twentieth year, where
she soon became known as a dramatic writer and novelift.
She also attracted the notice and engaged the affection
of captain Villedieu, who was already married, but from whom
she took the name of madame de Villedieu, by which she has
been chiefly known. The sudden death of a friend inspired
her with pious sentiments, which caused her to retreat to a
convent; but when it was known that her conduct had not
been of the most correct kind she was defimified. On her
return to the world she became acquainted with the marquis
de la Chaffo, and married him. She died in 1683. Her
works were printed in a collective form, in twelve volumes,
in the year 1702. They contain a number of novels, or short
romances, which were much read, and contributed to set afide
the long tedious romances at that time in fashion. She is one
of those writers who, by ascribing fictitious adventures to
known characters of antiquity, have so much contributed to
contend for truth and falsehood. Boulce.

JARECA, or JARECA, in Geography, a town of Syria,
in the Defert; 18 miles N.N.E. of Palmyra.

JARFO, a town of Sweden, in Hallingland; 36 miles
N.W. of Soderhamn.

JARGEAU, a town of France, in the department of
the Loiret, and chief place of a canton, in the district
of Orleans, situated on the Loire; 9 miles S.E. of Orleans.
The place contains 2,411, and the canton 7724 inhabitants,
on a territory of 150 kilometres, in 10 communes.

JARGEPOUR, a town of Hindooistan, in the circur
of Cuttack; 35 miles N.E. of Cuttack.

JARGON, in Mineralogy, See Zincox and Gents.

JARGONG, in Geography, a town of Hindooistan, in
Bengal; 18 miles S.W. of Midnapour.

JARGROD, a town of Poland, in the polacieate of
Braclaw; 36 miles S.S.W. of Braclaw.

JARHISAR, a town of Asiatic Turkey, in Natolia;
40 miles N.W. of Kiiatia. N. lat. 39° 43'. E. long. 30°
3'.

JARJARI, a town of the Arabian Irak, on the Tigris;
60 miles S.S.E. of Bagdad.

JARIPOLUS, in Aesop, in Antiquity, one of the Palmy-
renian gods. This deity, in all appearance, had the same
attributes with the God Lusus; for Jari signifies the
month over which the moon preceeds. Mem. Acad.
Inscr. tom. iii. p. 177.

JARISZOW, in Geography, a town of Poland, in the
polacieate of Braclaw; 56 miles S.W. of Braclaw.

JAR-KEVI, a town of Asiatic Turkey, in Natolia; 30
miles S.W. of Augura.

JARLSBERG, a town of Norway, capital of a district,
abounding in mines, in the diocese of Aggerhuus; 5 miles
N. of Tonberg.

JARMAN, a town of Africa, in Sahara. N. lat. 18°
57'. E. long. 9° 36'.

JARNA, a town of Sweden, in Dalecarlia; 35 miles
W.S.W. of Falhun.

JARNAC-CHARENTE, a town of France, in the depart-
ment of the Charente, and chief place of a canton, in the
district of Cognac, situated on the Charente; 6 miles
E. of Cognac. The place contains 1725, and the canton
10,420 inhabitants, on a territory of 162½ kilomteres, in
14 communes.

JARNANES, a town of France, in the department of
the Creufe, and chief place of a canton, in the district of
Bouflac; 16 miles S. of Bouflac. The place contains 727,
and the canton 6118 inhabitants, on a territory of 207½
kilometres, in 12 communes.

JARNOWICH, or GIORNOVICH, in Biography, one of
the most agreeable performers on the violin of the present
age, or perhaps of any age. He delighted, if not astonifhed
more, the oftener he was heard. No one had more facility
of execution, or executed with more grace the greatest dif-
ficulties. He composed concertos, which, without appear-
ing learned, or dividing the attention by the contrivance of
the inward parts, cherish the melody of the principal violin,
and give a relief to the most rapid as well as the most pathetic
periods of the cantilene. But such was the brilliancy of his
bow, that he always seemed playing with his part. His
flow movements never border on psalmody, but have always
a "unity of melody" of the most interesting and engaging
kind, so complete in taste and variety, as to fland in no need
of graces or embellishments to make it palatable. In his man-
er of playing, in the carriage of himself and his instrument,
there was a something for which we have no elegant word;
an ignorant and vulgar critic would perhaps call it a fangs.
If this performer, while in England, had been less capricious,
and of a temper more practicable, he might have governed
the musical world as despotically as Giraudini had done be-
fore, and been a much richer man than caprice and extrava-
gance.
J AR

gance would ever allow him to be. Though the French, with their usual ingenuity of disguising names, call him Jarnowitch, he wrote Giornovich, being by birth a Sicilian.

This admirable performer, after quitting England, resided a considerable time at Hamburg, where he was no less remarkable for his performances on the violin, than as a sword-man, a dancer, a billiard-player, and for feats of activity of all kinds. When in England, at the same time as the accomplished cresce, St. George, he was a match for him with the foils, and more than a match for the fencing-masters. And being a man of a difficult commerce, and very capable of his superiority in the use of arms, he was often captured and insulted in society, and wished for nothing more than opportunities of manifesting his talents. He had fought several duels in France and Russia before his arrival in England; and after quitting our island, he was wounded in the arm at Hamburg, in an affair of honour, so severely, that it was thought both his bow-hand and sword-arm were fo disabled, as never more to allow him either to fiddle or fight.

Some years elapsed before he was again heard of as a musician. During which tranquil period he seems to have fulfilled his career, being dextrous at all kinds of games. But in 1804, going again to Russia, accounts came to this country that he died at a billiard table at Peterburg, the latter end of that year.

Though Jarnowich's taste, fancy, and performance on the violin were so excellent, as a composer, he seems to have been self-taught, and not a regular bred contrapuntist. It has been found that, in his early youth he had been an apprentice to a rope-dancer and tumbler; which will account for his extraordinary agility, feats of activity, and dancing talents. He danced a harumpe, not only better than any of our sailors, but as well as Nancy Dawson, or Slingsby. The rest of his history is but little known. He arrived, at an early period of his life, at Paris, and delighted and astonished all hearers. In 1789 he had quitted that capital to visit other countries. M. Laborde, in his "Essay for the Mufique," tom. iii. published that year, gives him a great and just character for his captivating performance on the violin; but seems to over-rate his concertos, when he says they were as learned as agreeable.

JARNSKOG, in Geography, a town of Sweden, in Wirland; 38 miles N.W. of Carlstadt.

JARNUS, a town of Egypt; 13 miles N. of Abu Cirgey.

JAROCZOW, a town of the duchy of Warsaw; 20 miles W.N.W. of Kalish.

JAROMIRZ, a town of Bohemia, in the circle of Königgratz; nine miles N. of Königgratz.

JARON, or JARON, a town of Persia, in the province of Parthian, on the road from Ipsahan to Gamron. The houses are constructed of earth, and the mosques are mean. In the town and gardens are many palm-trees, highly esteemed by the Persians for their beauty and fruit, and furnishing a profitable article of trade; 80 miles S. of Schiras. N.lat. 28° 35'. E. long. 52° 42'.

JAROS, a small island of the Mediterranean, near the coast of France. N. lat. 43° 12'. E. long. 6° 25'.

JAROSLAV, a city of Russia, and capital of a government, deriving its name from it: it is large, well built, and commercial, situated on the Volga; containing eighty churches, three convents, above 6000 houses of wood, and more than 20,000 inhabitants. It abounds with manufactories of Russian leather, in which 6000 artisans are employed; first established by Czar Peter I., and rendered very flourishing by Ernest John, duke of Courland, during his exile in this place; 144 miles N.N.E. of Moscow. N. lat. 57° 25'. E. long. 20° 14'.

JAROSLAVSKOY, a government of Russia, bounded on the E. by the government of Kuldorm, on the N. by those of Vologda and Novgorod, on the W. by Tverkfo, and on the S. by Vladimir; about 160 miles in length, and from 30 to 110 in breadth. The capital is Jaroslav.

JAROSLAV, a town of Austrian Poland, in Galicia; 48 miles W.N.W. of Lemberg.

JAROSOT, a town of Poland, in the canton of Kiev; 36 miles W. of Bialacerkiev.

JAROTSANPOO, a branch of the Sanpoo, or Burmah-poster river, which rises in Tibet; 30 miles E. of Darnadija.

JARPOUR, a town of Hindooftan, in Bagiana; 24 miles E. of Bahbeleng.

JARRA, a town of Africa, in the Moorish kingdom of Luida; the town is extensive, the houses are built of clay and stone interspersed, the clay serving the purpose of mortar; the majority of the inhabitants is composed of Negroes, from the borders of the southern states, who prefer a precarious protection under the Moors, which they purchase by a tribute, to continuing exposed to their predatory hostilities. The tribute they pay is considerable; and though they manifest towards their Moorish rulers the most unlimited submission and obedience, they are treated by them with the utmost indignity and contempt. N. lat. 15° 5'. W. long. 7° 15'.

JARRAH, a town of Hindooftan, in Oude; 14 miles S. of Allahabad.—Ali, a town of Hindooftan, in the canton of Chandail; 30 miles W. of Sainpaur.

JARRETIER, in the Manoe, an obsolete French word, signifying a horse whose houghs are too close together; which is now expressed in French by croche, i.e. crooked or hooked.

JARRIE, LA, in Geography, a town of France, in the department of the Lower Clarante, and chief place of a canton, in the district of La Rochelle; 6 miles S. E. of La Rochelle. The place contains 1163, and the canton 9729 inhabitants, on a territory of 1745 kilometers, in 14 communes.

JARS, GABRIEL, in Biography, was born at Lyons in 1732. His father was concerned in the mines of the Lyons, and as the son discovered an early attachment to the art of metallurgy, he was placed in the establishment for the construction of bridges and canals, in order to obtain a practical knowledge of the business of a miner and civil engineer. He was soon fixed on as a fit person for introducing improvements into the art of working mines in France, and with this view he visited and strictly scrutinized most of the mines on the continent, and those in Scotland and England. On his return he set about arranging the observations which he had been able to make, when a sudden death in 1769 broke off his designs. His works were published by his brother at Lyons, entitled "Voyages Metallurgiques, ou Recherches et Observations sur les Mines et Forgés de Fer, la Fabrication de l'Aceur, celle du Fer-blanc, et plusieurs Mines de Charbon de Terre, &c," in three vols. 4to. They are said to form a complete collection of theoretical and practical metallurgy down to the time in which the observations were made. Gen. Biog.

JARUS, in Botany, a name by which some authors have called the crum, or wach-reeb.

JASAD, in Geography, a town of Persia, in the province of Segelian; 50 miles S. of Zareng.

JASENITZ,
JASENITZ, a town of Pomerania, on the W. side of the Oder, near its mouth; 10 miles N. of Stettin.

JASIDEANS, in the History of Religion. See JE-SIDEANS.

JASINE, in Botany, a name used by the ancients to express a small kind of climbing plant, much resembling that from which they obtained the drug called scammony. They, therefore, called this sometimes the small scammony, or scammonia parva. It climbed upon trees, and had small ivy-like leaves. Pliny has described such a plant as this under the name of laniing; and it seems very probable that this was only a corruption of the word jafme, that author having taken most of his accounts from the Greeks, and having frequently mistaken their names.

JASINGPOUR, in Geography, a town of Hindooftan, in Oude; 30 miles S. of Fyzabad.

Gen. Ch. Cal. Common Perianth, or rather Involucrum, of many alternate leaves, the inner ones narrowest, containing numerous flowers on short stalks, permanent; proper perianth superior, five-cleft, permanent. Cor. of each flower of one petal, regular, in five rather deep, lanceolate, spreading segments. Stam. Filaments five, short, awl-shaped; anthers oblong, connected at their base, their summits spreading. Pfl. Germen inferior, roundish; style thread-shaped, the length of the corolla; stigma swelling, cloven. Peric. Capsule roundish, with five angles, crowned with the proper calyx, membranous, imperfectly two-celled, opening by a round orifice at the top. Partition divided from top to bottom. Seeds numerous, nearly ovate, affixed to a flaked, globular, unconnected receptacle, in the lower part of the capsule.

Obf. The central flowers are often abortive, their stigma being more tumid and undivided. Linnaeus placed this genus in his Syngenesia Monogamia, an order now, by general consent, abolished.

There is said to be a perennial variety, about which we have often enquired in vain.

JASK, in Geography, a town of Croatia; 14 miles N. of Carlstadt.

JASKAS, a town of Sweden, in the government of Abo; 14 miles N.W. of Abo.

JASLO, a town of Poland, in the palatinate of Sandomirz; 72 miles S.S.W. of Sandomirz.

JASLOWITECZ, a town of Poland, in the palatinate of Kamienie; 14 miles N.W. of Kamienie.

JASLOWITZ, a town of Moravia, in the circle of Znaym; 10 miles S.E. Znaym.

JASMATUM, a medicinal oil, called also by the Persians jafme; it is made by putting two ounces of the white flowers of violet into a pint of oil of fefamum. It is used to moist the body after bathing, and is in great esteem among the Persians for its fragrancy, though it is a sort of fume which many would rather think offensive.

JASMINE, or JESSAMINE-TREE, in Botany. See JAS-MIUM.

JASMINE, Arabian. See NYCTANTHES.

JASMINE, Baiflard. See CESTRUM. See also LYCUM.

JASMINE, Cape. See GARDENIA.

JASMINE, Fennel-leaved. See Ipomea.

JASMINE, Ilex-leaved. See LANTANA.

JASMINE, Peru. See SYRINGA.

JASMINE, Red. See PLUMERIA.

JASMINE, Scarlet and yellow. See BIGNONIA.

JASMINEÆ, a natural order of plants, so called from Jasminum, which is one of them. This order is the 37th in Jussieu's fifth, or the fourth of his eighth classes, and is equivalent to the 44th of Linnaeus, or Sepiarix. For the characters of Jusieu's eighth class, see GENTIANÆ. The order in question is thus characterized.

Calyx tubular. Corolla tubular, regular; (in Fraxinus either wanting, or of four petals.) Stamens mostly two. Style one; stigma two-lobed. Fruit either capular (in the manner of the order of Acanthi), or pulp; in some cæses with two cells and two seeds; in others of one cell, with one, two, or four seeds. Embryo straight, flat, generally included in a fleshy albumen. Stem shrubby, more rarely arborescent, with opposite branches. Leaves for the most part opposite. Flowers either panicled in an opposite manner, or corymbose.

The sections are two.

1. With a capillary fruit. This contains Maytenus of Molina, with Nyctantes, Syringa, Hele (which is a Veronica), and Fraxinus.

2. With a pulpy fruit. This section consists of Chionanthus, Ola, Phillyrea, Magnorium (which is properly not distinct from Jasminum), Jasminum and Lysigrum.

The Jasminæ form an elegant and distinct order, valuable for the elegance of their flowers, which, moreover, are usually very sweet-scented, though in some instances unpleasantly strong.

JASMINOIDES. See LYCIUM.

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, oblong; permanent; its margin five-toothed and crept. Cor. of one petal, falver-shaped; tube cylindrical, long; limb flat, in from five to eight deep, somewhat elliptical, lobes. Stam. Filaments two, short; anthers small, within the tube of the corolla. Pfl. Gernem superior, roundish; style thread-shaped, reaching as high as the anthers; stigma two-lobed. Peric. Berry double, smooth, each of one cell. Seeds solitary, large, ovate-oblong, convex on one side, flat on the other, coated with pulp.

This delightful genus consists of 21 supposed species in Wildenow's Sp. Pl. Linnaeus confined it to those which have eight
eight segments in that part to 1\textit{Nyctanthes}, for want of attention to the fruit. This in the \textit{Arbor trifils}, the only true \textit{Nyctanthes}, is capsular, but in all his other species pulpy; for which reason Sir J. Banks and Dr. Solander first properly removed all such to the genus before us, of which their manuscripts contain descriptions of many more, hitherto unpublished. Eleven of Willdenow's species have simple leaves, eight ternate, and two pinnate ones.

Among the former are \textit{J. biflora} and \textit{pulexera}, figured in \textit{Serm. Exot. Bot. v. 2. t. 115}, and there shewn to be one and the same plant; in the same predication are \textit{augisliifolium} and \textit{vinitzium}, of which a plate may be seen in Rheede Hort. Mal. v. 6. t. 53. So that the number of species in Willdenow's first section is diminished to nine, and his whole number to 19. One of the most interesting of this first section is the Arabian Jafmine, \textit{J. Sambac, Nyctanthes Sambac} of Linnæus, a native of the East Indies, and very general in our flowers, where its elegant white blossoms, purplish in decay, are abundantly produced, and diffuse the sweetest possible fragrance. A double variety, sometimes feen, is highly valued; see Andr. Repof t. 197. A still finer variety is the \textit{Kudha Mulla} of Hort. Malab. v. 6. t. 51, figured also in Tili, Hort. Pfan. t. 30. This last, though easily propagated, was confined to the gardens of the grand duke of Tuscany, and not given to any one. Such rapid illiberality met with its just reward after a time, in the loss of the plant, which, if dispersed, might have been preferred.

In the second section are, among others, \textit{J. azoricum}, frequent in green-houses, valuable for its shining broad leaves, and sweet white flowers: \textit{J. fruiticans}, Curt. Mag. t. 461, native of the south of Europe, hardy with us, bearing yellow but scented flowers; and \textit{J. odoratiflumum}, Curt. Mag. t. 285, found in Madeira, very commonly kept in green-houses, for the sake of its very sweet and handsome yellow blossoms.

\textit{J. officinale}, Curt. Mag. t. 31, our common white jafmine, a native of the East, but so generally cultivated that it can hardly be found certainly wild; and the most showy Cattalian jafmine, \textit{J. grandiflorum}, are the only ones known with pinnate leaves. This last is much more tender than the officinale, with larger flowers, elegantly tinged with red underneath. It grows in India, nor is there any good reason for the name of Cattalian jafmine.

\textit{Jasminum}, in \textit{Gardening}, a genus containing plants of the hardy and tender, deciduous and evergreen, shrubby kinds; of which the species chiefly cultivated are the common white jafmine (\textit{J. officinale}); the common yellow jafmine (\textit{J. fruiticans}); the Italian yellow jafmine (\textit{J. humila}); yellow Indian jafmine (\textit{J. odoratiflumum}); the Spanish or Cattalian jafmine (\textit{J. grandiflorum}); the Arabian jafmine (\textit{J. Sambac}); and the Azorian jafmine (\textit{J. Azoricum}).

This last has varieties with white striped leaves, and with yellow striped leaves.

The second fort is extremely productive in suckers, and balls of earth about their roots, to the places where they are to grow up and remain.

And the different varieties are increased by budding or grafting them upon flocks of the plain or common kind. See Budding and Grafting.

In respect to the common sorts, they must be planted against walls, piles, or other fences, that may serve as a support. When planted as a standard, it is difficult to train to a proper head, and keep in order, without destroying the flowering branches which are the extremities of the same year's shoots. On this account they should be permitted to take their natural growth in the summer, and not be pruned or nailed till towards the latter end of March, when the frosts are over, to prevent their being injured by them.

But the varieties should be planted in a southern aspect, and a warmer situation than the common sort, especially the fliril, which, in very severe winters, should be protected with mats or other means.

The second fort may be increased by layers, or planting the suckers taken from the roots, in the spring or autumn.

The layers may be made as in the first fort.

The third fort is capable of being propagated either by budding or in-arch-grafting upon flocks of the second kind, or by layers of the young tender branches made in the autumn or early spring, the former being the better practice, as producing more hardy plants. It should have a rather warm aspect, as a south wall, and, in very severe winters, the protection of mats. It requires the same fort of pruning as the first fort.

The four following sorts are more tender in their nature and habits.

The fliril of them may be increased by seeds or layers of the young shoots. The seeds should be sown in the early spring, in pots of fresh light earth, plunging them in a moderate hot-bed, and when the plants are up, removing them into a second hot-bed to forward them, giving them frequently light refreshings of water and gradually hardening them to the full air. They should be occasionally watered in the winter, and in the spring following be removed into separate pots, the earth being carefully preferred about their roots. Their first growth may be promoted by placing them in a mild hot-bed. They afterwards require a pretty free air and slight protection from frost in winter. They should have the decayed branches pruned out in the spring, without the others being shortened, as the flowers are produced at the extremities of the branches.

In the latter method the young shoots should be laid down in the early spring, as about March, being lightly nicked underneath at a joint, and often lightly watered in dry weather. In the following spring they may be taken off, and planted out in pots filled with light earth, separately; being afterwards managed as the others.

They may likewise be raised by in-arch-grafting into flocks of the second species, but the plants produced in this way are not so strong as those upon their own flocks, and they are apt to send out too many suckers from the roots.

The second of these tender kinds may also be raised by budding or in-arch-grafting upon flocks of the first species, which renders it more hardy than its own; but the plants are mostly brought from Italy, in bunches of four together, and which, after having their roots moistened, and the flocks and dead parts pruned away, as well as the tops cut down to within a few inches of the grafted parts, may be planted in pots filled with light fresh earth, plunging them in a moderate hot-bed, shading them from the sun, and giving them water. When they begin to grow, all the flocks below the
the grafts should be rubbed off, and the top shoots cut off, and air being admitted, so as to gradually harden them to be set out in a warm situation. They must have the protection of the greenhouse in winter, and be frequently sparingly watered, a free air being admitted in mild weather.

The third of these tender sorts may be raised by layers and cuttings; but the first is the best method, as the cuttings require much care to make them strike. The young branches should be laid down in the spring, in pots filled with soft loamy earth, plunging them in a hot-bed, and watering them occasionally. In the autumn, when they have frilled root, they should be taken off, and planted out in separate small pots, plunging them in a hot-bed, due shade being given. The cuttings may be planted in pots of the same sort of earth during the summer, plunging them in a hot-bed, and covering them close with a bell or hand glofs, due shade being given, and occasional waterings. When they have taken good root, in the beginning of autumn, they may be removed into separate pots, and be managed as those from layers.

These plants succeed best when kept in the stove.

The last of these tender sorts may be increased in the same way as the fourth species, and requires the same management afterwards.

The three first species may be employed as plants of ornament for covering walls, palings, and other naked erections about houses, as well as occasionally introduced as standards in clumps, borders, and other parts of picturesque grounds.

The other sorts afford variety among other potted greenhouse and stove plants. Some may likewise be trained against warm walls or palings, especially the last kind which has a fine fragrance, and at the same time a good appearance.

JASMUND, in Geography, a peninsula of the island of Rugen, which forms, with another peninsula called "Witto," a large bay, fronting the north-east, which, in hazy weather, often proves destructive to vessels. The bay is called "Trempwerwick." N. lat. 54°, 35'. E. long. 13°, 45'.

JASOUN, a town of Asiatic Turkey, in the government of Sivas, on the Black sea; 75 miles N.E. of Samfoun.

JASPACHATES, in the Natural History of the Ancients, a name given to some varieties of the agate-jasper, mentioned under No. 5. in the following article.

JASPER, Jaspis, Fr. Jaspis, in most other European languages; a mineral species belonging to the class of earthysimilar, and divided by Werner into fix sub-species distinct from each other, both by their cryctognatic and geognatic characters; viz. 1. Egyptian jasper; 2. Ribbed jasper; 3. Porcelain jasper; 4. Common jasper; 5. Agate jasper; and 6. Opal jasper. They agree in their being opaque or slightly translucent at the edges, in hardly ever affecting vivid colours, in their always occurring massive and in common external shape (except the Egyptian jasper); in their hardneds being rather inferior to that of common quartz. The remaining external, in conjunction with the geognatic, characters have been thought sufficient by Werner to divide the jaspers into the above sub-species, which by some other writers are considered as varieties only. Some jaspers are nearly related to heliotrope, others approach the nature of indisputable clay, argillaceous iron-flone, and lithomarge; the opal jasper passes into the opal.

Almost all coloured jaspers, according to Hauy, are conductors of electricity; a property observable by bringing them into contact with an electrified conductor, when, on the approach of the finger, they emit sparks.

1. Egyptian Jasper; Egyptian jasper. Quartz jaspe panachi, Hauly; Callos d'Egypte, Fr.; Egyptians Kiesel,宁宁, Germ.; Sites tigyanus, Nilotthis, Lat.

Brown and yellow are the predominant colours of this jasper, and generally several shades of them occur together in the same piece. The brown is usually a deep chestnut or liver brown, sometimes approaching to blackish brown, and an admixture of red is likewise observable; at Bonden a variety is said to occur in which the red predominates. The yellow is mostly a deep umber-yellow, also greyish yellow; it likewise passes into several shades of pale red. Two of these colours are generally mixed in such a manner that the one, particularly the brown, forms the ground, while the other represents a succession of variously colored, concentric, irregular zones or bands, and spots which, in conjunction with black dendritical and other delineations, often produce representations of grottos, landscapes, human figures, and other objects.

It has hitherto been found only in rolled mottly oblong pieces, and in the form of balls, with uneven surface. These have also been found hollow, drufed with brown quartz crystals; but such specimens are very rare.

Be it externally and internally it is moderately glimmering; infusible more or less resinous. Fracture flat conchoidal. It is very easily fragilable. Its hardneds is rather less than that of quartz. Fragments indeterminately angular and very sharp-edged; perfectly opaque, and only slightly translucent at the edges. Specific gravity 2.654, Drillon; 2.60 Brunnich.

Before the blow-pipe the Egyptian Jasper is insufable without addition. When ignited for a considerable length of time it loses its colour.

The proportion of the component parts of this substance must, of course, be subject to considerable variation, according as the brown or yellow mass predominates. A variety analyzed by Dehmelherie, yielded:

This Jasper is found pretty abundantly in Egypt, particularly in the neighbourhood of Cairo and Suez, on the borders of the Nile. According to Dr. Renus, it occurs also, as rolled pieces, at Kofchatek, in the Buzhau circle of Dobania. It is also said to be found at Freise in Lotharingue.

Of its geognatical situation, no more is known than that it always occurs in rounded pieces, which appear not to owe their origin to rolling, but to be original, and produced by infiltration. It has been ingeniously remarked by Mr. Mohs, that the interior of these balls is generally found to agree exactly with their exterior form, in the same manner as in some hornstone-balls, in which the nucleus is separated from the surrounding coatings by a coniforme coating of crystallized quartz, &c. If this be the case, neither the colour, nor the delineations in the Egyptian Jasper, can be considered as derived from without, nor its form as a secondary one; and we may further infer from this, that the balls of this Jasper, (at least those of the brown variety from Egypt,) are formed like agate balls in rocks belonging to the formation of the amygdaloid. Werner, as we are told by Mr. Jahn, suspects that it occurs imbedded in a brown ochre of iron. Mr. Patrin is of opinion, that these rounded mafles have originally been simple ferruginous geodes, formed in marly ferruginous soil, abounding with iron ochre, which has moulded itself into oval mafles com-
Jasper.

posed of concentric layers. These layers, in the progress of time, will shrivk both by defication and the effects of the mutual attraction of the ferruginous molecules, which have a perpetual tendency to enter into the closest possible combination. The layers of the geode, by their condensation, become more or less separated from one another, and its centre remains empty, in the whole mass is composed of nothing but pure oxyd of iron; but when mixed with marle, this latter is continually pressed towards the centre, where it forms a nucleus more or less light coloured, in proportion as it has parted with the iron it contained, and which has united with that of the neighbouring layers. In the ordinary way of occurring, (Mr. Patrin observes,) it appears that these geodes remain nearly in the same state in which they were formed; but in Egypt some particular circumstance has made them undergo a new modification. Decomposition, or other circumstances which may have altered the nature of the foil that contained these geodes, must have caused the development of various fluids, which penetrating through the pores of the geode, and combining with the fluids it contained, have formed there the siliceous matter in the same manner in which water is formed by the combination of hydrogen and oxygen.

Cordier observed this jasper to enter into the composition of an Egyptian breccia, made up of a great variety of rounded stones; and it is supposed that those places where this breccia forms extensive beds, the greater part of the rolled pieces that are seen there, owe their present detached state to a disintegration of such mafes.

The Egyptian jasper is much esteemed on account of its delineations, which are of very often angular; and as it is susceptible of a very high polish it is cut by lapidaries into thin pieces for snuff-boxes, brooches, &c.

It always exhibits two, three, or more colours together, which are disposed in alternating, straight, feldom waved, stripes or layers. The colours are yellow, green, and pearl-grey; yellow, and greenish-white, ochre, and ifa-bell-yellow, mountain, and leek-green, fleshy, cherry, and brownish-red. It is always found marlified, internally it is dull; the lustre it occasionally exhibits proceeding from admixed heterogeneous particles.

Its hardness is less than that of quartz. It is brittle and easily frangible; fracture conchoideal, but sometimes approaching to splintery or earthy; also a tendency to the flaty fracture has been observed in some varieties. Fractures indeterminitely angular, sharp-edged. Specific gravity from 2.500 to 2.800.

The ribband jasper is found in Siberia, particularly in the districts of Kolwan and Catherinebourg; in Sicily; Corfca; Switzerland; in Germany, at Grandstein and Wolfitz near Hrofburg, in the Leipzig district; at Ilmenau in Henneberg, at Talkenstein, on the Hartz, and in the Palatinate. It probably occurs also, according to Jmeunou, in the Pentland hills near Edinburgh.

The geogepic relations of this jasper appear to be sufficiently distinct from that of the others, it forms considerable mafes and beds, with whole connection, however, we are as yet unacquainted. The ribband jasper of the Hartz, as connected with grauwacke on which it rests, cannot be doubted to be subordinate to the transition rocks. Mr. Patrin considers this jasper and all others that occur in beds, and are entirely opaque, to be primitive; and most of the Siberian jaspers are in that predicament. He refers to the secondary jaspers, all those that have a vitreous fracture combined with a slight degree of tractulidity. But several circumstances connected with the geognostic occurrence of the different jaspers, prevent us from admiring this distinction.

The finest Siberian ribband jasper is found, together with other varieties, in the hills that border on the southern part of the Ural mountains, about 100 or 150 leagues northward of the Caspian sea, in the neighbourhood of the fortrefs of Orlka. The red and green layers of this jasper being so well defined and regular, it is made ufe of for several purpofes of ornament, particularly for cameos. It is not found in large masses. Patrin informs us, that when fecn in its native place, it appears to admit of being quarried in blocks of several feet in fize; but as soon as the rock is wrought, it separates into small pieces.

Its principal colour is a bluish-grey, of various intensity, generally intermediate between pearl-grey and lavender-blue. It is also found yellow, such as ochre and flavus, and even pale orange-yellow, which paffes into brick-red. Clove-brown and liver-brown are likewise mentioned among its colours; as also blufh-black and mountain-green. Sometimes several of these colours occur together in spots, and in flamed and clouded delineations. The blufh-grey varieties, however, exhibit generally but one colour, besides the red and yellow-brown colour on the rifs, and the red or brown coloured impresfions of various vegetables.

It occurs commonly marlified, and sometimes in blunt-edged and rounded rolled pieces, which, in the rents they exhibit, bear evident the marks of the acfion of fire.

Internally its lustre is inconsiderable; it feldom approaches to fhining.

Its hardness is inferior to that of moft other jaspers; it is very brittle: fracture imperfectly conchoideal, approaching to even; fragments indeterminately angular, pretty sharp-edged; perfectly opaque; specific gravity 2.350, Kirwan; 2.653, Wiedeman.

By the continued application of intense heat, the porcelan-jasper, according to Wiedeman, may be futed into a black fcoria. But the yellow variety, operated upon by Klapproth, fowed no change either in the clay or charcoal crucible, except that in the former it was feen to contract, and its surface to become dark feal-grey and dull, while in the charcoal crucible a small piece became black and glifhening, and acquired a yellow-brown surface.

The constituent parts of the pearl-grey variety, from Stracke, in Bohemia, are flated as follows by the late Mr. Rofe, by whose death the world has loft one of the moft accurate analysts.

This substance is found in Bohemia (at Schwinthitz, Stracke, near Carlsruhe, &c.), in Saxony (at Plauen), in the Upper Palatinate, in Helv. (near Almenrode), in Saarbrück (at Dutwiler), in Siberia (at Kufnezov, in the district of Kolomna), Iceland, &c. It occurs in considerable masses, and obviously owes its origin to the action of subterraneous fire; Werner therefore ranks it with his pseudo-volcanic, or such fossils whose nature has been considerably altered by the proximity of that agent. That it has not been in a state of fusion is proved by the impregnations of plants so frequently observed in it, and which bespeak the fossil to have originally been that variety of flate-clay which belongs to the coal formation. We accordingly find it in company with burnt clay, earth-flags, &c. in countries which have either formerly experienced the ravages of subterraneous fires, or where beds of coal are actually in a state of ignition.

It is a fact worthy to be noticed, that at Dutwiler, in the county of Saarbruck, which not long ago experienced the spontaneous inflammation of a bed of coal, both porcellain-jasper, and other pseudo-volcanic substances, are seen as it were in a progressive state: they are more or less changed in proportion to their distance from the principal seat of the subterraneous fire; and the vegetable impregnations which they exhibit are in every respect the same with those observed on the flate-clay.

The porcelain-jasper has obtained its name from its appearance, and the circumstances connected with its origin. It takes a moderate polish, but is not applied for ornamental purposes. Indeed, there are feldom any large pieces of it found without rifts and fissures.

Its principal colours are brown, red, and yellow; the brown is yellowish, reddish, clove, liver, blackish-brown, approaching to black; the red is tile, and blood-red of various shades, feldom flint-red; the yellow is mostly ochre-yellow, which passes into greenish-yellow; also various shades of green are observed among the colours of the common jasper, such as mountain, verdigris, and olive-green, but they are feldom frequently met with. Several of these colours are sometimes seen together in small irregularly bituped, spotted, and clouded delineations.

It occurs commonly massive, but also alternating in thin layers with quartz, &c. and disfigured, as in the blood-stone; it is likewise found in blunted-edged rolled pieces.

Internally its luster is intermediate between glintening and shining; it is rather vitreous.

It is nearly of the same hardness as the preceding sub-species; it is brittle and easily frangible; fracture more or less perfectly conchoidal, approaching in some varieties to splinterly, from which it passes into fine earthy. Fragments indiscriminately angular, pretty sharp-edged: they are generally opaque, but now and then translucent at the edges. Specific gravity, 2.580 to 2.700, Kirwan; 2.652 to 2.693, Sauflure; 2.666, Muefenbrock; 2.692, Blumenbach.

Common jasper is inflexible without addition before the blow-pipe; it only loses its colour by the application of intense heat; with borax it is dissolved without ebullition, while soda and phosphoric acid combine with it in an imperfect manner only; when urged by oxygen gas it is converted before the blow-pipe into a white or dark grey globule.

According to Kirwan the common jasper consists of

Mr. Lampadius thinks that he has found that the reddish-brown variety is generally coloured by the oxyd of uranium and some iron, the proportion of the uranium being about three per cent.

Among the localities of the common jasper are: Saxony (Altenberg, Geising, Freiberger, Sieferderf, Schneeburg, &c.); Bohemia (Jehkner mountains, &c.); Sicily (Bunzlaus, Landhut, &c.); Salzburg; Steurnark; Hungary and Transylvania; Italy, particularly Sicily; France; Scotland (according to Jameson, in the transition rocks near Edinburgh), the Shetland Islands, Norway, &c.

The common jasper is exclusively a production of veins; it occurs in such as are chiefly composed of iron ore, to which indeed it appears to bear great geochemical affinity. The substances with which it occurs together in these veins are red and brown iron-stone, iron-flint, quartz, opal, lithomarge, &c.; as also, sometimes, galena, pyrites, and vitreous silver. But common jasper is also found disseminating veins for itself without any metallic ores, and only accompanied by some amethyst or common quartz, which in this case generally occupy the middle of the vein. It likewise occurs as a confluent part of agate bals in amygdaloid. At Salzburg it is said to have been found in calcareous and clay flate rocks, and at Offenbany, to form the basis of a particular kind of porpory, but this latter observation seems to be founded on error, since all the Transylvanian varieties of porpory, that have fallen under the observation of Werner, and other mineralogists well acquainted with the true characters of jasper, have pronounced them to belong to the clay, horn-stone, and pitch-stone porphyries.

Molt varieties of the common jasper are susceptible of a tolerably good polish, whence they are frequently cut by the lapidaries, and formed into snuff-boxes, buttons, sealstones, &c. (see Gems, engraved &c.); some varieties that may be procured in voluminous blocks are wrought into tables, mantle-pieces, small pillars, and other objects of ornamental architecture. The following are most frequently seen in the hands of the lapidaries:

The red jasper, on which we possess some very fine antique engravings. It is found at Giuliano, at San-Stefano, at Cornicata, and at Monte-Vago, in Sicily; and occurs also in the vicinity of Geneva, in the valley of Chamouni; at Grenoble, in the department of the Isère; and at Mont-More, in the department of the High Alps. Canavain, in Piedmont, is said likewise to furnish good red Jasper. This should not be confounded with iron-flint and fine, which is a variety of quartz.

The yellow jasper: it is seldom found in large pieces, and only used for inlaid work, mosaics, &c. The belt is found at Giuliano, in Sicily; and it occurs also in the valley of Chamouni, and between Varec and Grenoble, in the department of the Isère. This variety is seldom found equally tinge'd, but often traversed by white and red veins.

Brown
Brown jasper of various shades. This is the most common, and most frequently seen converted into objects of ornament, vases, pedestals, &c. It takes a very fine polish.

What the Italians call Paragoni is, properly speaking, the Lydian flone; but the name is now and then applied to a black variety of jasper, much esteemed by lapidaries for seal flones, &c. It is said to be found at Giuliano in Sicily. (Also a black marble is sometimes improperly called Paragoni.)

The existence of a jaspe white variety of common jasper is doubted by some. What goes by this name is a white flone marked here and there with fine red lines; but it has been seen cut and polished only, its nature is not determined with accuracy. Another white jasper is mentioned by Hermann as occurring in more elevated parts of the Altai mountains, near the source of the Korgoo; it is marked with black dendrites. Specimens before us have the appearance of horn-flone.

The gala&cites of Pliny are, by some writers, considered as a white jasper.

5. Agate Jasper; Jaspagates; Agat Jaspis, Germ.
   Its colour is flesh-red, reddish-white, and brownish; also yellowish-white, which parleys into flabellum, irraw, and greenish yellow. These colours form concentric rings, and figures resembling plans of fortifications, &c.

It occurs massive. Has scarcely any luster. Is rather less hard than common jasper. Its fracture is small and flat conchoidal, approaching to even. The other external characters are those of the preceding species.

The agate-jasper is often found in agate veins, and in agate balls occurring in amygdaloidal and porphyry rocks. It is cut and polished.

6. Opal Jasper, Quartz rufine commum, Haucy.
   Its principal colours are shades of red; flesh-red, scarlet-red, brick-red, blood-red, cherry-red, brownish-red; it also occurs reddish and yellowish-brown, and feldom ochre-yellow; these colours exist variously mixed, as spots and veins in the same piece; sometimes they are uniform.

It occurs massive.

Internally its luster is more or less shining, and intermediate between vitreous and resinous.

It is nearly of the same hardness as the preceding sub-species, brittle, and easily frangible. Fracture large or small flat-conchoidal. Fragments indeterminately angular, sharp-edged, fearce translucent at the edges.

The preceding characters agree partly with those of the opal; and indeed the geognostic relation of the opal-jasper is perfectly the same as that of the opal. It is mostly found nodulating in porphyry, sometimes in veins, and in both cases it is commonly accompanied by common opal.

Its principal locality is Kafchau, Tockay, in Hungary, and it is also found near Conflantinople, and in the mountains of Kolyvan, in Siberia.

JASPOXY. See Jasper, No. 2.

JASQUE, in Geography, a town of Persia, in the province of Mecran, which gives name to a cape in the gulf ofOrmuz. N.lat. 25° 40'. E. long. 50° 4'.

JASSARI, a town of Sweden, in the Lapmark of Kimi, in the gulf of Bothnia; 50 miles N.N.E. of Kimi. Also, a river of Sweden, which runs into the gulf of Bothnia, at the above-mentioned town.

JASSELMARNE, a country of Hindoostan, bordering on the lower part of the course of the river Padder, and on the sandy desert, which, as well as Nagore and Bick nơi, form a number of petty rajahships, and are underfoot to be moiily inhabited by Rajpoos.

JASSENES MARMOR. See MARMOR.
JAT

deep, roundish, spreading, convex segments, concave underneath. Stam. Filaments ten, awl-shaped, approaching each other in the middle, the five alternate ones shorter, all erect, shorter than the corolla; anthers roundish, versatile. Pfr. a slight rudiment in the bottom of the flower.

Female, Cal. none. Cor. rosfause, of five petals. Pfr. Germen superior, roundish, with three furrows; styles three, cloven; stigma simple. Perix. Capsule roundish, three-lobed, three-celled; each cell with two valves. Seeds solitary, roundish, large.

Obf. J. knew it fade to have but nine flaments. Willdenow reckons 17 species of this genus, of which about eight were known to Linnaeus, though not very perfectly. For examples of Jatropha may serve J. penduliflora. Andr. Repof. t. 267. Curt. Mag. t. 604. (J. acuminata; Venten. Jard. de la Malaisf. t. 52.)—A native of Cuba, remarkable for its fiddle-shaped leaves, and beautiful deep scarlet flowers.

J. Curcata. Jacq. Hort. Ind. v. 3. t. 63; a native of South America, sometimes kept in the flowers of botanic gardens.

J. Manilkot, whose root makes the Calaba bread in the West Indies, being, though a virulent poison, rendered sweet and harmless by washing its grated substance. All these are thorns. The leaves of the whole genus are flaked, alternate, generally lobed, and often palmate. Flowers corymbose.

JATTS, a tribe of Hindoos, who long since the death of Awarungzeb erected a statue in the province of Calcutta and Delhi. They appeared at first no other man than at hand, but at last formed a regular state, and fixed their capital at the city of Agra, and appear to have possessed a tract of country, along both sides of the Jumna river, from the neighbourhood of Ghwalior to that of Delhi; in length about 160 miles and 50 broad. Col. Dow, in 1700, estimated their revenue (perhaps extravagantly) at 200,000, all of which is supposed to amount to 70,000 men. This nation is traced by P. Wendell from the countries lying between the S.E. confines of Moulfat and Goloud. Tamerlane, it is certain, made war on a people, called the "Gates," in his march from Battrin to Samath. Nudjuiff Cawn, at a late period, disposed the Jats of their whole country, except the confined territory of Bhartpur. Madhoj Sindia has, in turn, ripped Nudjuiff Cawn’s successors of these conquests, which are now fearfully rising, although a few years ago, under Soorge Mull, they ranked among the most flourishing provinces of Hindoostan. The Jats no longer exist as a nation; all that remains to Runjat Sing, the son of Soorge Mull, being the fort of Bhartpur, or Burtapot, situated about 45 miles on the west of Agra, with a small territory of four or five lacks of rupees. The rajah of Goloud is of the Jat tribe, but unconnected with Runjat Sing. Rennell’s Memoir.

JATTENDALS, a town of Sweden, in Helsingland; 16 miles N. of Hudwickfall.

JATTIR, in Scripture Geography, a city of Dan (Joh. xx. 43.), afterwards given to the Levites of Kohath’s family. (Joh. xxi. 14.) Eusebius says, that it is situated in the district of Dora, towards Malta, about 20 miles from Eleutheropolis.

JATTRA, in Geography, a town of Bengal; 15 miles N. of Midnapour.

JAV

JATTS, a small island in the Atlantic, near the coast of Guinea. N. lat. 11° 48’. W. long. 15° 50’. JAU DE ST. ELIAS, a town of Brazil, on the river Negro; 70 miles W. of Fort Rio Negro.

JAVA, one of the largest islands constituting the Archipelago in the East Indian Sea, about 650 British miles in length, and in medial breadth about 150 miles, situated between 5° 45’ and 8° 48’ S. lat., and 105° and 114° 40’ E. long. This island lies nearly in the direction of E. and W., and to the S. and W. its shores are washed by the southern Indian ocean. On the N.W. lies the island of Sumatra, from which it is separated by the straits of Sunda; to the N. Borneo, from which it is separated by the Java sea; to the N.E. at a considerable distance, Celebes; to the E. and Bali, divided from it by a narrow passage, called the straits of Bali. This island is the southernmost of those four large islands, the other three being Sumatra, Borneo, and Celebes, which were formerly known by the appellation of the Sunda islands; and when the Dutch company first established themselves here, Java was divided into three large empires, viz. Bantam, Jaccatra, and the empire of the Soeoeoeohnam, which last was the most extensive, and comprehended full two-thirds of the whole island, Cheriron being feudatory to it. But it is at present divided into five slates or empires, viz. Bantam, Jaccatra, Cheriron, the empire of the Soeoeoeohnam, and that of the Sultan; which altogether contain 123 provinces, or governments, the kingdom of Bantam being considered only as one. The four first of these are dependent on the Dutch, as to be under engagements to deliver their produce to the Dutch, and not to sell any of it to any other nation. Each province, or government, consists of a certain number of villages, or families, and a number of which, throughout the whole of Java, including Bantam, amounted, in the year 1777, to 152,014. These families are estimated to consist of 612,084 persons; and if to these we add the inhabitants of the principality of Madura, which, though a separate island, is always considered as connected with Java, and contains 100,000 families, or 60,000 persons, the whole population of Java and Madura will amount to 972,084 persons. Huygen, however, gives the population of Java, exclusive of Madura, as follows: viz. in the kingdom of Bantam, 5000 families, in Jaccatra 33,914, in Cheriron 15,000, in the Mataram, or empire of Java Proper, 94,200, making in all 145,114 families, which, allowing six individuals to each family, will give 888,684 for the whole number of inhabitants; but from more recent accounts he infers, that the population of Java is 14 or 2 millions of people. These statements do not include the inhabitants of Batavia; which see. A chain of high mountains, commencing to the E., in the province of Balkamang, and running through it to the W., but decreasing in height, divides Java longitudinally into two parts, of which the northern portion is the largest and the belt. The north coast has every where a low and woody foreland, with some hills, particularly W. of Bantam, where the high land stretches down to the sea-coast. This island has several deep bays on the north side, as those of Bantam, Batavia, Cheriron, Samarang, Joana and Sourabay, which afford every where good anchorage. The south coasts are much less known than those on the north. In the good monsoons, the sky is almost always clear, except near the time of the breaking up of the monsoons, when many and violent thunder storms rapidly succeed each other. In the bad monsoons, the south winds, which then prevail, bring with them heavy rains and violent thunder-forms, without much alteration in the temperature; the thermometer, in the warmest part of the day, generally standing at between 82° and 88°. The effect of this de-
gree of heat is much moderated by the alternate land and sea breezes, which blow every day in regular rotation. The thermometer seldom varies more than two or three lines. Thunberg mentions several volcanoes in this island, one of which had overwhelmed with ashes a great number of coffee plantations. Java is watered by a great number of rivers, which descend from the chain of mountains above-mentioned, but none of them are navigable for large vessels. The soil is everywhere a reddish granulated clay, which in the dry season is so hard, as to be incapable of cultivation without much moilmenting, but with little labour it is extremely fertile. Ploughing is performed with buffaloes, which abound in this island. In general agriculture no manure is used; but the gardens are moistened with water in which oil-cakes have been foaked, and which renders the soil rich and fat. The only method which the farmer takes with his land consists in burning upon it all the weeds and rubbish which it produces; and when one piece of ground ceases to yield sufficient crops, recourse is had to another; and the land is suffered to lie fallow for several years, after which it again recovers its fertility. The articles produced in this island are much more valuable than those of all the neighbouring countries; of these the first article is rice, which not only supplies the inhabitants but provides for the eastern provinces and the island of Ceylon: this rice is of two kinds, one sort being set nearly under water and another sort planted in the rainy season, on high ground and upon the mountains; the former, however, is the best, and bears the highest price. The pepper of Java is also a profitable article to the Dutch company, and so is the sugar, the belt of which is from the province of Jaccatra, which fee. Coffee is likewise a produce very advantageous to the company, the greatest quantity being furnished by the provinces of Jaccatra and Cheribon. Cotton is also a produce of Java of great value. Java also yields to its poff-dors the article of salt. The N. E. coast of the island, and part of the district of Cheribon, afford a very large quantity of timber, logs, beams, boards, &c. which not only supplies Batavia for various purposes, but admit of an annual exportation of a considerable quantity to several of the out-factories, and in particular to the Cape of Good Hope. Indigo, though it be not an original production of Java, has been cultivated with tolerable success since the Dutch company have been established here. Turmeric, long pepper, and cubebos, are also productions of this island. This island abounds with fruit-bearing trees, such as the cocoa-nut palm, the Suri tree, which yields the palm-wine or toddy, china-oranges of a larger and smaller size, the tamarind-tree, the flindock, the durion or durian-tree, the fruit of which resembles the broad-fruit, and which is considered as diuretic, sedative, and serviceable in expelling wind, the Siftaka-tree, the mango-tree, the mangojan, lemon and lime-trees, pineapple, and many others.

The native inhabitants, called Javanese, whether they belong to the kingdom of Bantam, or to any other part of Java, are of a middling size, generally well proportioned, of a light brown or yellow complexion, with a broad forehead, and flat thin nose, curving downwards at the tip. The hair is black, and always kept smooth and shining by the use of cocoa-nut oil. They are in general proud and insolent, as well as cowardly. Their principal weapon is a kind of dagger, called a "kris," which is often poisoned, and causes immediate death. Arrogant towards their inferiors, they are no less crouching with respect to their superiors, from whom they expect any favour. Their dress consists in a piece of cotton, wrapped round the waist, and drawn between the legs, fo as to be fastened behind. They are otherwise naked, except that they wear a small cap on the head. Those of superior rank wear a wide Moorish coat of flowered cotton, or other stuff, and in general turbans. They suffer no hair but that of the head to grow. The dress of the women is little better than that of the men, except that it is more close and covers more of the body; the hair of the head, worn long, is turned up, and twisted round the head like a fillet, fastened with long bodkins of various materials, and adorned with flowers. Men and women are fond of bathing. Children of both sexes are entirely naked till about eight or nine years of age. Twelve or thirteen is their age of puberty. The Javanese are polygamists, and besides their wives, who are as many as they can maintain, they take their female slaves for concubines. The women are more comely than the men; they are extremely jealous; and punish those whom they suspect of inconstancy and infidelity by the administration of emaculating drugs. Their habitations, rather huts than houses, are constructed of split bamboo, interlaced or matted, plastered with clay, and covered with the leaves of the cocoa tree. The entrance is low, and they have neither door nor shutter. The whole house consists usually of one apartment, in which husband, wife, and children, and also their poultry, of which they keep a great number, lie together on the ground. Their chief food is boiled rice, with a little fish, and their drink is water. They take a little arrack when they can obtain it, and are almost always chewing betel or pining; and likewise a sort of tobacco, produced here, and therefore denominated Java tobacco. This they smoke through pipes made of reed. They sometimes put opium into their pipes with the tobacco, in order to invigorate their spirits; but the continual use of it rather deadens them. They have neither tables nor chairs; but fit upon the ground, on mats, with their legs crossed under them. They make no use of knives, forks, or spoons, but eat with their fingers. They have a certain kind of musical instrument, called "gongchime," consisting in hollow iron bowls, of various sizes and tones, upon which a person strikes with an iron, or wooden stick, and which emit sounds like a set of bells. They are very fond of cock-fighting, for which they keep a peculiar breed. The tax upon their game-cocks forms part of the revenue of the province of Jaccatra. One of their favourite diversions, at which they are very dextrous, is a kind of tennis-play; in which they strike the ball, which is of the size of a man's head, hollow, and made of matted reeds, with their feet, knees, or elbows. Their manner of cultivation consists in touching the forehead with the right hand, accompanied by a slight inclination of the body. The Mahometan religion, introduced into Java by the Arabsians, is predominant over the whole island; though it is said, that far inland, over the mountains, towards the S. side of the island, there are still some of the aboriginal idolatrous natives. Mofques are erected all over the island, and there is a famous one near Cheribon. They are very particular and nice about the tombs of their saints, and will suffer nothing unwbecoming to be done upon or near them. They do not bury their dead in coffins, but simply wrap them in a piece of white linen, and having deposited them in the grave, place two stones upon it, one at the head, and one at the feet. These stones, they believe, are to serve as seats for the two angels, who, after their death, examine into their conduct, while in this world. They have both male and female physicians, who are paid to perform wonderful cures by means of their knowledge of the medicinal and vulnerary herbs. Much friction of the affected part is one of their chief means of cure. This is done with two fingers of the right hand, which are pressed down by the left, and passed continually downwards, after having first anointed
Anointed the part with water mixed with fine ground wood, or with oil. The coin of Java is of lead, like that of Sumatra and Borneo. The language of Java is the Malay, or a dialect somewhat akin to it. The original inhabitants of the country are not suffered to be made slaves, but are free people, governed by their own emperors, kings, and governors. The capital of Java is Batavia; which see.

Java Head, the western point of the island of Java. S. lat. 6° 47'. E. long. 107° 40'.

Java Sea, that part of the East Indian sea, which lies between the island of Java to the north, Sumatra to the west, the islands of Banca, Billiton, and Borneo to the north, and the island of Celebes to the east.

Javat, or Tschavat, a town of Peru, in the province of Schirwan, at the union of the Aras and the Kur; 45 miles S. of Scamaniche. N. lat. 39° 55'. E. long. 48° 16'.

Javelin, a kind of spear, or half-pike, used by the ancients both on horseback and on foot.

It was five feet and a half long; and the fleed wherewith it was headed, had three fides, or faces, which all terminated in a point.

The javelin was one of the Gymnastic exercises among the ancients, and confined either in throwing a stone, or a dart, or something else, with the most address, and to the greatest distance. Plato (De Leg. 1. viii.) admitted two sorts of "Joculations," the first called τα ξύλη, and the other οὐσίαν τα ἄρματα; and Galen informed us, that Apollo and Echecampus were the inventors of them. The Latins translated the first by the word "Sagitatto," and the second by that of "Joculatio." In those exercises they equally employed either a bow or a sling, or another instrument, which they made use of for hanging to the arrow a thong which they held in their hand, to take the more steady aim.

Javenby, in Geography, a town of Sweden, in Weft Bothnia; eight miles S. of Pitea.

Jauer, a principality of Sileia, bounded on the N. by the principalities of Glogau and Sagan, on the E. by Lignitz and Schweidnitz, on the S. by Bohemia, and on the W. by Bohemia and Lusatia. It is mountainous and covered with wood; and it yields pit-coal and mill-iron. The mountains contain various ores, with numerous mines of iron and copper. The warm baths of its mineral springs are much frequented. It has 12 towns, and several large villages, which contain 200 families and upwards; and among their inhabitants are artificers, particularly weavers, whose manufactures are purchased for exportation. Its earthenware is much esteemed. Jauer, its capital, is situated 16 miles N. of Schweidnitz. N. lat. 51'. E. long. 16° 18'. Its other principal towns are Hirschberg, Lowenberg, and Bunflau, which give names to districts.

Javerda, a town of Hindoostan, in Dowlatabad; 10 miles S. of Calberga.

Jauja, a city of Peru, famous for its manufacture of woollen cloths, and mines of silver.

Javie, L. A., a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Digne. The place contains 130, and the canton 2401 inhabitants, on a territory of 75 kilometres in 10 communes.

Jauiesmow, a town of Hindoostan, in Oude; 15 miles N. of Corah. N. lat. 26° 25'. E. long. 86° 46'.

Jauldoe, a town of Bengal; 142 miles N.W. of Calcutta. N. lat. 21° 26'. E. long. 86° 7'.

Jaulino, a town of Hindoostan, in the circar of Aurungabad; 28 miles N.E. of Aurungabad.

Jausm, among Carpenter's, denote the door-posts, as also upright posts at the end of window-frames.

Jausms, among Bricklayers, &c. the upright sides of chimneys, from the earth to the mantle-tree.

Jaundice, in Medicine, from the French jauniff, (which again is from jaune, yellow,) a disease which is principally characterized by a yellowness of the skin over the whole body, and of the coasts of the eye.

The appellation of Aurigo has been also given to this disease, from aurum, gold, in allusion to the yellow colour of the skin. The Romans called it morbus regius, or the royal disease, and morbus arcautus, or arcautus, the origin of which names has afforded matter of dispute to the etymologists, who have not come to any satisfactory conclusion on the subject. Cellius believes that it was called regius, because it requires rich or royal fare to cure it. And the term arcautus is laid to have originated from the various colours of the skin resembling those of the rainbow. By the Greeks it was denominated ἀκρήτους, ἄκρητος; whence also ἀκρῆτη. Sauvages has adopted this last as the title of the fifth order, of his tenth class of diseases, understanding by it "aceritata" (couleurs dépravées) morbid changes of the complexion, and denoting jaundice by the term Aurigo. See his Nofol. Method. — Allas Van Swieten Comment. Aph. 918.—And Celsus, lib. iii. cap. 24.

Jaundice is marked by a yellow colour of the whole surface of the body, which is first seen, and is most conspicuous, in the tunica conjunctivatis, or white part of the eyes; and at the roots of the nails. The urine is thick, of a deep yellowish brown colour, and tinges linen and other white sublunates, immersed in it, of a yellow hue. The bowels are often convulsive, but sometimes loose; and the stools are commonly of a very pale and clay-like appearance both in consistence and colour, from the absence of bile, and have not the usual feculent smell. This disease is accompanied with a fenest of much latitude and langnor, and a great inaptitude to exertion; with lowness of spirits, and a feeling of pain and tension, or weight and oppression about the precordia; there is also frequently much anxiety, and some degree of difficulty of breathing, as well as a troublesome fenest of itching over the skin, unattended by any eruption. Many symptoms of indigestion are generally prevalent; such as nausea, vomiting, flatulency, and eructations, and loss of appetite; solid food tastes bitter in the mouth of some patients; and in some states of the disease hiccup occurs, and occasional paroxysms of rigor or chills. The pain is sometimes extremely acute in the epigastrium, or pit of the ileum, or in the right hypochondrium, especially during the pain of a gall-stone. The state of the pulse varies much; in general it is somewhat quicker than natural; but in some cases, and particularly under the circumstance just mentioned, it is slower. There is a popular notion that all objects appear of a yellow colour to patients labouring under jaundice; and, indeed, Galen, Hindmann, Boerhaave, and Sydenham, all affect that they have occasionally witnessed that circumstance. But, on the other hand, Dr. Heberden, and other physicians of much observation and experience, have never found such a change of vition in any patient, nor have we ever met with any living practitioner by whom it had been detected. It is not, indeed, an impossible case, particularly where the disease has been of very long continuance and great intensity, when, should the cornea or humours of the eye become impregnated with bile, the light would pass through a yellow medium, and objects thus be tinged of that colour. But these parts are not usually found impregnated with bile.

The symptoms of jaundice originate from the mixture of bile
bile with the circulating blood. In its ordinary state the blood contains no bile, nor any other of the secretions, such as urine, saliva, &c.; but the bile is generated from the blood, by a different combination of its parts, which is produced by the action of the vessels of the liver. When thus generated or secreted, as the term is, the bile is conveyed to the intestines by a duct which opens into the duodenum, or upper part of the alimentary canal. Branching from the middle of this duct, however, is another duct, which leads to the gall-bladder, into which the bile regurgitates. This is called the cystic duct; and that part of the duct of the liver above the branching off of the cystic duct, is called simply the hepatic duct: but the part below, or between this and the intestine, being the common channel for the bile from the liver, and for that which had regurgitated into the gall-bladder, is called the "common biliary duct," or ductus communis cholecodochus. Thus much it seemed necessary to state, in order that our future observations may be understood. For a minute account of the structure of the parts, see Liver.

Now, after the bile is secreted, if the hepatic, or the common duct be obstructed, so that the passage of the bile into the intestine be prevented, it is forced back into the liver, and is taken up by the absorbent vessels, and carried into the maws of the circulating blood, in the former of which it is diffolved, and thus gives it its own yellow colour. The blood, thus tinged, carries the dye with it to every part of the body, and hence the general hue of jaundice is produced. It would seem, however, that the bile, in a liver distended by obstruction of the ducts, is not only taken up by absorption, but is also forced into the mouths of the hepatic veins, according to the observations of Dr. Saunders and Dr. Powell. For both these gentlemen have witnessed the presence of bile in the thoracic duct on dissection; and Dr. Saunders found the serum of the hepatic veins in a dog, in which jaundice had been a short time before produced by a ligature on the common biliary duct, evidently more loaded with the colouring part of bile, than the serum in the other veins of the body. (See Saunders's Treatise on the Structure, Economy, and Diseases of the Liver. Powell's Obs. on the Bile and its Dificases, &c. p. 56.) When the bile reaches the circulation, the intensity of tinge which different parts receive will be in proportion to their vascularity, and the quantity of colouring matter thus carried to them; or to the natural hue of the part being more or less calculated to show it, as in the eye and white of the nails. All the solid parts of the body, except the medullary substance of the brain, as some have affirmed, even the bones themselves, the fat and the cartilages, have been observed to be deeply tinged of a yellow colour. The secreted fluids are generally also deeply tinged. In cases of some duration, the permeable matter is coloured, so likewise is the saliva, which has a very bitter and bilious taste: but the urine is much more highly impregnated with bile, and more speedily than any other of the secretions. Indeed the milk is the only exception which is made by authors; for the affection is supposed to extend even to the fermen. (Van Swieten.) As we have already stated, however, poetic licence seems to have got the start of observation, in affirming that the bilious tinge extends to the humours of the eye, which has not been detected by modern inquirers.

"Lurida praetera spectacula que cumque tuerunt Arquat!"

Lucret. lib. iv. v. 333.

is probably without any foundation, as well as Shakespeare's allusion to the same purport. (See Heberden, Med. Tranf. vol. ii. p. 132.) The fluids, which are often preternaturally collected in the cavities of the body, as in those which constitute the varieties of dropy, and those which are accumulated in bladders upon the surface, in consequence of the application of blisters, or other acid matters, to the skin, are also found tinged with bile; and so likewise is that fluid which, under some circumstances, is collected in the ventricles, and which, in other respects, differs materially from the effusions into other cavities. Powell, loc. cit.

It is generally stated that colicinensis attends the jaundice, in consequence of the want of bile, which is believed to be the principal stimulus to the intestines. But Dr. Heberden justly remarked, that icteric patients are often disposed to have a purging, and that certainly neither of these states is peculiar to the disease: and Dr. Powell observes, that the greater number of patients, whom he has attended, have been rather purged than otherwise. He remarks, that the degree of the colicinensis militates much against the notion, that it originates in a deficiency of bile in the intestines. "Supposing for a moment," he says, "that bile is the stimulus imagined, it acts with a definite force, exemplified in the daily occurrence of stools: now, under these circumstances, any common purgative stimulates the intestines still more, and produces more copious evacuations; but where bile is absent and there is colicinensis, even the strongest purgatives fail in their effect, as far as their stimulating power goes, they must infinitely surpass any quantity of the bile itself. If, too, this deficiency was the sole occasion of an unpleasant a symptom, it might be thought that the bile of animals might be advantageously employed for its removal: but even this does not answer, nor has a ferment of insipid ox-bile stimulated my intestines to more frequent or copious discharges. Upon the whole, I think that colicinensis ought not, in this case, to be attributed to absence of bile, and that bile is certainly not the stimulus which has been imagined." (P. 87.) This reasoning is by no means conclusive; but it puts the matter in a probable light.

Causes of Jaundice.—The causes which obstruct the passage of the bile out of the liver, are to be found in the various circumstances which can obstruct, comprese, or diminish the caliber of the biliary ducts, particularly of the ductus communis. Under these three heads we shall treat of the individual causes of the distress. Powell, loc. cit.

1. Of Obscurations in the Biliary Ducts, or of the causes which plug up those passages. The ductus communis is liable to obstruction from two causes, namely, from gallstones, biliary calculi, or concretions, as they have been termed, and from a morbid inspissation or density of the bile.

1. Gall-stones are generally formed in the gall-bladder, and acquire their chief bulk there; but from what cause these crystallizations take place we are altogether unable to state. While they remain in the gall-bladder they are perfectly harmless; and when they are very small they readily pass with the cystic bile. The principal inconvenience, then, arises upon the accident of their being carried from the cyst into the narrow ducts. Biliary concretions are very frequently found in the gall-bladder, in the dissections of dead bodies, when no symptom has appeared during the life of the person to excite a suspicion of their existence.

When a gall-stone is impacted in the duct, a pain, which is often most acute and severe, so as to be hardly supportable, but sometimes moderate, is produced, and is often accompanied by shiverings, which afterwards occasionally recur. The pain is felt at the pit of the stomach, and seems generally to be confined to that point of the epigastriac region which corresponds to the situation of the opening of the common
common duct into the duodenum, and from this part it appears to dart through to the back: the pulse at the same time continues nearly as slow as is natural, and has none of the hardnefs attendant on inflammation. By an attention to the seat of the pain and this natural flate of pulse, Dr. Heberden observes, that it is not difficult to verify the outward yellowness in many cases, some days before it appears. The breath, during the culmination of the pain, becomes short and hurried; there is great general anxiety and reftlesness, sometimes amounting to delirium, and at laft great depression and fainting; the stomach is affected by nausea and retching; and there are often irregular spasmodic twitches in various parts of the body. There are often profuse sweats, which are, however, sometimes absent; and they do not depend at all upon the fweats, for they are sometimes present, when no hivering has occurred. These symptoms do not continue long in all their violence; for although the patient, during the passage of a gall-flone, is never free from some pain, yet it increases, by paroxysms, to a flate of acute fuffering, and fubfides again into one of comparative cafe, during which there is a fene of deep-feated forenefs and fulnefs of the epigastric and right hypochondriac regions. The greatest relief from pain is experienced by bending the body forward upon the knees, in which position the relaxation of the abdominal muscles leaves the affected parts fubje&ed to the leaft pressure. Another fit, perhaps of equal or greater violence than the firft, then comes on, and alternates with another refforation; this may occur feveral times in an hour; but sometimes the duration of the paroxysm is much longer.

At fome early period of these attacks, the jaundice makes its appearance; and it continues for a confiderable time after the violent fymptoms have disappeared. When the converion has paffed, however, and the more urgent fymptoms have ceafed, the yellownefs may foon be perceived to diminifh in its intensity; but before it can entirely disappear, it requires that the whole quantity of the tinged fereum be removed by a gradual operation of the excretory glands, and a frefh fupply in a natural flate be introduced.

The duration of the attack, including the whole time of the paffage of the converion, is as various as its intensity; fometimes a few hours, fometimes feveral days, or even weeks elapfe, before it is expelle. In the former cafe, the paffage is often fo rapid as not to allow time for the jaundice to take place. The number and fize of the converions falso vary much; fometimes the gall-bladder is filled with them; at other times there are not more than one or two: fometimes they are small and angular; at others large, and have a more regular furface. They have been fometimes seen nearly of the fize and figure of the gall-bladder itself, fo as almoft to fill the whole cavity. These large converions are lefs frequently the caufe of jaundice than thatmaller ones; for, from their bulk, there is but little probability of their entering the ductus cysticus, and afterwards of obstructing the ductus communis: it is from calculi of smaller dimensions that fuch obstructions generally arife. It appears, however, that calculi of confiderable bulk muft have paffed; for the obfervations, that is not been found, on defection, enlarged to an inch in diameter; an infance of which was met with by Dr. Heberden. But converions have paffed during life of fuch a bulk as to occafion a doubt whether they escaped into the intestines by the natural canals, or made their way thither by a preternatural paffage; as by the adhesion of the gall-bladder, in confequence of inflammation, to the duodenum or colon, after which ulceration had occurred, and opened a communication. Dr. Chelfon, of Gloucefter, fome years ago met with a cafe where a gall-flone of unufual magnitude paffed during life, and the patient recovered. Some years afterwards he died of another complaint; and on examination, it appeared that this large gall-flone had made a preternatural paffage through the gall-bladder into the intestine.

Mr. Clive has an infance of the fame kind in his collection of anatomical preparations, at St. Thomas's hospital.

It would be foreign to the purpofe of this article to enter into a minute account of the varieties of appearance, and the chemical properties of the different bilary converions. Upon these topics the reader will find feveral obfervations under the head of Billary Calculi; and he will find a moft ample investigation of the whole fubje& by Dr. Powell's "Obfervations on the Bile and its Difeafes," from page 105 to 133.

The chief circumfance which feems to give rife to the formations of these converions in the gall-bladder and bile ducts, is a life of indolence and inactivity; it matters not whether it may have been paffed amid the luxuries of wealth, or the hardships of poverty; and if the disorder be more common in the former situation, it is perhaps because necessity compels the fubjects of the latter to more personal exertion. Hence these converions are comparatively more frequent in women than in men; thofe men who are engaged in literary pursuits are very liable to them; and in either fex they are moft common after the active period of life is past. Haller noticed the frequency of their occurrence in criminals, whole death had been preceded by long confinement. (Opificula Patholog.) They are often found in the gall-bladders of oxen, which have been flailed during the winter mouths; and Dr. Powell believes that they occur in a larger than common proportion of maniacs who have been long confined.

Dr. Saunders explains this influence of a fedentary life on the bilious secretion, by observing that the excretory powers of the liver depend but little upom any action which the biliary ducts can perform, as they poifea a very small degree of irritability; but are aflifted principally by the agency of the diaphragm and abdominal muscles, and the perifhtical motion of the intestines; and more especially from the agitation which the hepatic feftum undergoes during bodily exercise. The want, therefore, of a degree of exercise, efficient to affift the biliary ducts in their excretory function, muft necessarily lay an ample foundation for morbid aflections of the bile. And the necessity of this external aid to the perfect action of the liver, feems more obvious from the circumfances of its venous circulation, which is always more languid than in those fecretory organs, where the fluids are kept in a state of more rapid motion by arterial impulse.

It is commonly fuppofed that the biliary converions are protruded from the ducts by the contractile power of the ducts alone. The truth of this opinion, however, Dr. Pemberton has questioned; and he maintains, that the gall-dome is propelled by the accumulating bile behind it, which at the fame time pushes it forward and diflends the duct. For, in the firft place, the duct, he affirms, is always found contracted before the gall-dome; whereas, if the converion were protruded by the contractile power of the duct, it ought to be contracted behind it. In the fcecond place, opium and blood-letting are employed as relaxants and antipafmodics, and succfufally: but this relaxation would rather retard than expedite the paffage of the calculi, if its protrusion were the reft of the contractile power. The conformation is, therefore, of practical importance. See Pemberton on Dis. of Abdominal Vifera, p. 55, et seq.

It may be added, that exceffive vomiting and violent exercife, which have given rife to jaundice, operated probably
JAUNDICE.

ably by forcing concretions from the gall-bladder into the ducts; and that there is an instance on record, in which jaundice arose from the seeds of gooseberries, which were found in the extremity of the common duct, as it enters the duodenum. Saunders.

2. The canal of the ductus communis cholecodochus may be obstructed or plugged up by the secretion of bile of a morbid density and tenacity, or by the insinuation of it in the gall-bladder. Dr. Saunders, speaking of the appearances that have been observed on dissection, says, "the bile has been found of a very viscid and pitchy consistence, especially in the gall-bladder; passing from the cystic to the common duct, and thereby perhaps rendering the passage of the bile difficult, which would otherwise flow freely into the duodenum." The colour of this dense and insinuated bile is still yellow, according to Dr. Powell, who states, that it does not seem to block up the large ducts, nor enter into the duodenum, but rather accumulates in the liver itself, the deviation from a state of fluidity rendering its passage through the smaller canals difficult. He conceives that this state of the secretion is connected with the use of spirits. Loc. cit. p. 75 and 145.

II. Compromise of the Biliary Ducts.—The passage of the bile into the intestines may be also impeded by the various circumstances under which the common duct, or the hepatic duct is placed in a state of compromise; of these we may mention the following:

1. Phlegm.—All persons who are engaged in sedentary occupations, yield very generally to a curved posture, which, independently of the more remote effects of such modes of life, has seemed sufficient to produce jaundice. It is a well known fact, at least, that under such circumstances the disease is particularly frequent. Dr. Powell remarks, that in the necessity of attention to anatomical dissection, which is given by young men in their preparation for the profession of physic, it is by no means uncommon to find attacks of jaundice, and that this at so early a period of their confinement, as can scarcely admit of the supposition that this was the chief exciting cause; and in some cases of literary study the same fact is observed: now the only circumstance in common in these two situations, is the flexure of the body forwards. In such a posture, the gall-bladders are obviously liable to suffer constant compression between the liver and the intestines and other adjoining parts.

2. This compression may be also occasioned by the gravid uterus, in pregnancy, towards the latter periods of which jaundice occasionally occurs. Dr. Powell, however, is inclined to refer the jaundice, produced under such circumstances, to the peltoric state of the liver, in which the accumulation of blood in that viscus itself is the cause of the compression of the ducts; more especially because blood-letting, and other evacuations remove it.

3. Tumours of the liver and of the neighbouring viscera are among the common causes of the most permanent and severe jaundice. A mere concretion of blood or turgescence of the vessels throughout the liver, as just hinted from whatever cause produced, may be easily supped and pressed upon and block up the biliary ducts, and thus occasion the abstraction of that bile, to the secretion of which it ministers. Thus hepatica, or inflammation of the liver, is sometimes accompanied by jaundice; and would probably be more frequently so accompanied, were it not in general confined to a small part of the viscus, or to its investing membrae. Thus, after the intermittent fevers of this country, and the analogous remittent of warmer climates, a jaundice often comes on towards the conclusion, which has been considered as forming no very unfavourable prognostic; for there does not generally appear to be any other diftance of bile in such cases, than an increase of its size, with great accumulation of blood through its substance. Dr. Powell mentions the case of a woman who died of consumption, and whose lungs were found to be almost one mass of ulcerated tubercles; within the last three days of her life, jaundice had come on to a very intense degree. But, on dissection, the ducts were found free, and the gall-bladder empty, and no external tumour was discovered; but in the liver there seemed to be a great accumulation of blood; it was much increased in size, had a loofe texture, and was in every part deeply tinged with bile. Loc. cit. p. 72-3.

Scurrous tumours of the contiguous parts, as of the head of the pancreas, of the pylorus, and even of the liver itself, serofulous enlargements of the lymphatic glands in the capsule of Glisson, and metastematic swellings of the omentum, are often so situated as to obstruct mechanically the passage of the bile into the intestines; tubercles of the liver have sometimes also operated as extraneous causes, and, from their local situation, stopped the natural course of the bile. But the liver is often much enlarged by collections of large tubercles, which yet leave, in their interstices, a perfect freedom for the action of the vessels and the passage of the biliary ducts; and cirrhosis of the liver is not usually a general disease, but is confined to particular spots, which are often out of the way of the biliary passages; so that it has often been found, on dissection, to have made considerable progress without inducing jaundice.

4. Diffusion of the large intestines by air, which constitutes the disease called tympanites, is often accompanied by jaundice. Such a diffusion, arising to a certain point, must impede the influx of the bile into the duodenum, both by its pressure upon this bowel itself, and upon the biliary ducts; and the jaundice seems to take place, under such circumstances, only when the diffusion is very considerable, and is therefore to be deemed a very unfavourable symptom. In a case, mentioned by Dr. Powell, the accumulation of air was so great, that, very speedily after the appearance of jaundice, the cecum was burst by it, and the patient of course destroyed.

III. The calibre of the biliary ducts being diminished, independently of internal stoppage or external prefire, jaundice will equally ensue. Two causes of this kind are mentioned by medical writers; but it is probable that neither of them are of very common occurrence.

1. Spasm of the common duct, or a spasmatic contraction of the duodenum itself, and consequently a closing of the aperture of the duct, are particularly mentioned by Dr. Cullen among the causes of jaundice, and Dr. Powell deems the fact well established, although it has often been denied. In some way or other, however, jaundice frequently concurs with diseases that are called spasmatic. Thus it is said by Sydenham to come on occasionally during hysterics; and it has been observed to follow violent fits of anger, and other emotions of the mind. Dr. Heberden denies the accuracy of Sydenham's observation, in respect to hysteria, both from his own observation, and the authority of many other practitioners. With respect to the influence of the passions, Dr. Saunders remarks that anger not only augments the quantity of bile secreted very considerably, but likewise vitrifies it; hence it is, that, being carried into the duodenum in large quantities, and resorbed into the stomach, it produces the same effects as an emetic; and hence
probably the term choleric, as applied to passionate people. If the ductus communis do not transmit it as fast as it is secreted, and the gall-bladder is full that it cannot receive the excess; then it will be forcibly returned upon the hepatic system, and, by entering the blood-vessels, produce jaundice. (Saunders, p. 235.) So, have supposed, during the general commotion of the passages, a gall-stone may have been pulled from the bladder into the duct, and thus produced jaundice; but the whole attack has often been too transitory, and too free from the general symptoms of the passage of a gall-stone, to allow of such a supposition. (Powell, p. 70.) The symptoms of fever, affecting the parts in question, are, however, generally considered as being similar to those of the passage of a concretion. (Pemberton, loc. cit. p. 49.) So that, on the whole, the explanation which Dr. Saunders has given, of the influence of the passages in producing a temporary jaundice, appears to be the most probable.

2. A thickening of the coats of the biliary ducts, by which their calibre must be diminished, is mentioned among the least common causes of jaundice. (See Morgagni De Causis, etc. Sess. 14. Art. 12.) Pemberton observes, who mentions an influence of the total obliteration of the common duct. Dr. Saunders remarks that this contraction of the canal of the duct is produced by the extension of diseased structure, originally produced in the stomach by the abuse of spirits and liquors, to the biliary ducts. "In the dilatation of those who have been intemperate dram-drinkers, the diseased structure may be traced," he says; "from the stomach along the course of the ductus communis, and I have frequently seen these ducts so contracted and thickened, that they could not transmit bile." A similar effect, from inflammation of the liver extending to the gall-bladder and ducts, which often lays the foundation of an incurable jaundice, has been observed by Dr. Pemberton: the inflammation of the duct may be removed, he observes, but the thickening remains, a permanent evil. Dr. Darwin, however, imagines that a temporary jaundice may be occasioned by an inflammatory thickening of the membrane lining the ducts, analogous in its kind to that of the membrane of the nose in catarrh, and which, like it, soon ceases, and the jaundice will go off. (Zoophonia, vol. ii. p. 138.) The truth or falsity of this opinion it is not in our power to ascertain.

In addition to the series of causes already detailed, arising from obstruction to the passage of the bile into the duodenum, it has farther been a question, whether any obstruction to its discharge from the bowels, after it has cleared its appropriate ducts, may not likewise occasion its absorption into the system, and therefore produce jaundice. It would appear, from an experiment of M. Portal, that this may happen. He pulled a ligature round the intestine of dogs, a little below the opening of the ductus communis choledochus, and observed that, in five or six hours afterwards, their eyes acquired a yellow tinge; and upon examining the livers, he found them filled with bile. (Mem. de l'Acad. des Sciences, ann. 1777.) In some of the cases of obstructive colitis accompanied by jaundice, that are on record, it is probable, therefore, that the jaundice was a symptom, rather than a cause, of the colitis.

This seems to be the case, in the flight jaundice of infants, which speedily vanishes when the bowels are unloaded. Dr. Powell mentions a paralytic of the gall-bladder as one of the causes of jaundice. In this case, as in the urinary bladder, the powers of contraction are lost from over-excitation, and the accumulation of bile is said to have become so great, as to produce a tumour externally, with an evident fluctuation, which has induced the surgeon to puncture it, under an idea that the collection was pus. It is not easy to conceive how jaundice should be induced, under these circumstances, except by absorption from the inner surface of the gall-bladder itself.

The prognostics in jaundice, must be obviously very different in different instances, according to the nature of the obstruction upon which it depends. In jaundice arising from gall-stone, or pafm, the prognostics is favourable; for, in the latter case, the pafm will invariably cease; and, in the former, if the stone is small enough to enter the duct, it is most likely that it will pass its whole length, inasmuch as the canal at the entrance is of less diameter, than when it unites with the hepatic duct to form the ductus communis choledochus. If, therefore, jaundice has arisen suddenly in young and vigorous habits (even though accompanied with much pain), and is unattended with fever, and other unfavourable circumstances to be mentioned, it is seldom of long duration, and may be effectually removed. The itching of the skin, which sometimes subsides after a few days, Dr. Pemberton observes, often returns after two, or three days, before other evident proofs of the removal of the obstruction; so that he considers such a recurrence of the itching as a favourable symptom. A bilious diarrhoea coming on, implies the removal of the obstruction, and must therefore be regarded as conclusive with respect to the recovery of the patient. A small variation of the yellowness cannot be relied upon as a symptom of convalescence; since the colour of the eye and skin often undergoes slight changes, even during the time when the obstruction remains the same. Pemberton, loc. cit. p. 61.

Among the unfavourable symptoms may be reckoned a continued of the intenseness of the yellow colour in the eye, the pain of the stomach remaining equally acute, and confined to the same spot, and an increase of saftle, while the foals and urine continue to retain the unnatural colours before-mentioned. The appearances are very unfavourable, if, with the violent pain, there is also a quick pulse, lots of flesh and strength, with occasional watchfulness and melancholy; under these circumstances, the patient becomes subject either to profuse sweating or hemorrhage. These symptoms generally mark the presence of some fixed disease in the vifcera, and the disease frequently terminates in a confirmed dropsey of the belly.

It must not be omitted, that jaundice is a disease into which the patient is very liable to relapse, after every appearance of recovery.

Diagnosis.—It is extremely important, with a view to the proper treatment of jaundice, to distinguish from which of the causes of obstruction before-mentioned the biliary ducts are impeded. Our conclusions as to the event of the disease must also depend entirely upon our knowledge of the nature of the obstruction. We have in some measure anticipated the diagnostic symptoms, in treating of the causes; but it cannot be too carefully observed, that where gall-stone, or pafm, of the ducts, is the cause of the jaundice, there is most acute pain in the pit of the stomach, attacking suddenly, commonly remitting and returning in paroxysms, and often accompanied by vomiting; but at the same time the pulse continues in its natural state, both in respect to slowness and softness, which implies the absence of inflammation. When shiverings occur, it may be observed that they come on after the pain has continued some time, and do not precede the pain, as is the case with those shiverings which attend inflammation.
JAUNDICE.

Jaundice arising from compression of the biliary ducts, by tumours of the neighbouring organs, may be distinguished by the pain not having come on suddeily; by its being less acute and varying little in degree; by the circumstances of the general health, when the jaundice has been preceded by other diseases of long continuance, by wasting of the flesh and strength, and is accompanied by forebears or obvious hardness in the hepatic or epigastric region, and by an increased velocity of the pulse, and when it occurs in the middle or advanced period of life. Even when the jaundice has subsisted long without any intermission, (Dr. Cullen remarks,) and without any pain in the epigastric, an external compression is to be suspected. When to these circumstances a disposition to dropsy is added, there can remain no doubt as to the existence of morbid enlargement of some of the vasa of the liver, and of the incurable nature of the disease.

The phlegmasia, to which young women are extremely subject, puts on, to a superficial observer, the appearance of jaundice; and, indeed, the whole body aches, in some cases of this disorder, to much of a yellow colour, as might lead a less circumspect observer to suspect the presence of bile. But in all such cases, the original whiteness of the eye remains, or is even increased to a pearly whiteness, and the urine remains of its natural colour, affording us that the circulating fluids hold no bile in solution.

Cure of Jaundice.—As the cure of jaundice consists essentially in removing the obstruction to the free egress of bile from the liver, the treatment must vary according to the nature of the obstructing cause; and while measures are adopted, with a view to remove these causes, other collateral indications, such as the alleviation of pain, the diminution of inflammation, if any be present, and the support of the patient’s strength, will require to be fulfilled.

When the symptoms lead us to infer, that the jaundice arises from the impaction of a gall-stone in the duct, the object of remedies will be to facilitate its passage into the intestinal canal. We know of no certain and immediate means of expediting the passage of biliary concretions, which is generally a work of time, depending upon the gradual dilatation of the biliary duct. It proceeds, however, faster or slower upon different occasions; and therefore the jaundice, after a various duration, oftentimes subsides spontaneously. This circumstance has given rise to a belief in the efficacy of a number of remedies, many of which are perfectly inert, and others cannot be supposed to exert any effect upon the passage of a gall-stone. Some of these, indeed, seem to have been recommended for the cure of jaundice, in consequence of their yellow colour; such as saffron, the yolk of raw egg, &c.; in the same way as the root of madder, which is red, has been popularly used as an emmenagogue. Of such remedies it is unnecessary to give any farther account.

But although no immediate evacuation of the obstructing cause be within the power of medicine, yet that process may be facilitated by those means, which are known to abate increased action of mucous fluids, and to diminish irritability. I.e. by anti-spasmodic and narcotic medicines. Opium is one of the most effectual medicines of this class; and the benefit, resulting from its administration, seems to confirm the theory upon which it has been recommended. It fulfils the two-fold indication of relaxing the spasm of the ducts, and alleviating the urgent pain: if it is not enough, however, to administer small or even ordinary doses of this medicine, which, in proportion to the severity of the pain, will produce the least effect. The quantity of opium, as Dr. Pemberton enjoins, ought to have no limit but the absolute alleviation of the pain; and till that object is attained, the patient should take a grain of solid opium, or twenty-five drops of the tincture of it every hour. (Pemberton, loc. cit. p. 52.) Or, as is recommended by Dr. Powell, which we believe to be more efficient, he should take a large dose, say two or three grains, in the first instance, and follow this up by smaller doses, at short intervals, which will prolong the powers of the medicine, and sometimes the concretion will pass, while the patient is under its influence. (Powell, p. 155.) A dose of fifty drops or a drachm of tincture of opium, in a gyller, will frequently produce immediate relief.

The spasmodic constrictor of the duct, and the excursive pain attendant upon it, may be also alleviated, and the passage of the concretion facilitated, by the use of warm fomentations, applied to the region of the stomach and liver, and full more effectually perhaps by immersion in a warm bath; the temperature of the bath should, however, be properly regulated, as well as the continuance of the immersion. As the object, in this case, is to obtain the soothing and relaxing effects, and not the corroborant operation, of the warm bath, its temperature should be from 100° to 101° Fahrenheit’s thermometer, either on the first immersion, or by the application of subsequent heat; and the immersion should be continued till an incipient faintness is produced, which, whether it take place after a longer or a shorter time, is the best criterion to regulate its duration; for when this has not ensued, the bath has not appeared to produce any beneficial effect. Powell.

Several physicians, and Dr. Cullen among the rest, have considered the action of vomiting as the most probable means of affording the passage of a gall-stone through the biliary duct. This action, Dr. Cullen says, “by compressing the whole abdominal vasa, and particularly the full and dilated gall-bladder and biliary vessels, may contribute, sometimes gently enough, to the dilatation of the biliary duct.” (First Lines, § 185.) Hence emetics have been frequently recommended for the cure of jaundice arising from gall-stones. Dr. Heberden, apparently by a dereliction of his usual rational caution, while he admits that vomiting is often an urgen t symptom of jaundice, from biliary concretion obstructing the duct, and that the action may even be supposed to contribute to lacerate the duct, if the concretion be strongly impinged in it; yet he maintains that experience had taught him that vomiting, excited while the pain was intense, rather quieted than ageravated the pain, and never brought it on. (Medical Tranafct. of the Coll. p. 160.) He considers it, therefore, as a judicious practice, whether the patient have a vomiting or not, to order an emetic, either at first, or as soon as the intensity of the pain has been alleviated, and occasionally to repeat it, watching at the same time its operation, and checking it by an opioue, if the straining continue too long, or be too violent. It is true, that no decided injury is stated to have been produced by such an exhibition of emetics; yet the theory of their operation, by mere mechanical conduction, seems very problematical, and experience, on the whole, does not attest any very clear proofs of their efficacy. Dr. Cullen admits that gentle emetics alone should be given; and he adds that, where, by the long continuance of the jaundice, it may be suspected that the size of the concretion then passing is large; or more especially when pain attending the disease gives apprehension of inflammation, it may be prudent to avoid vomiting altogether. On the whole, the practice must be deemed precarious where the disease
JAUNDICE.

is fever, and uncalm for where it is mild. When the obstruction is occasioned by infusinated bile or mucous about the mouth of the duct, vomiting might remove this, and thus care the diffuse; but a purgative, which is less precarious in its operation, is perhaps equally efficacious.

The use of purgatives, indeed, has been recommended by some writers, with the view to aid the expulsion of gall-stones from the biliary duct; but the most experienced agree that little benefit can be expected to accrue from the use of cathartics (except when the bowels are very colicky), until the concretion shall have escaped into the intestine. There cannot be a doubt, however, that flight_ofs of jaundice, depending perhaps upon the clogging of the aperture of the duct with infusinated bile, or a very small calculus, are speedily removed in many cases by cathartics. From the notion that constipation arose from a deficiency of bile in the intestines, the bitter purgatives were particularly recommended in jaundice; such as aloes, infusion of chamomile with tincture of aloe, or columba with rhubarb and foxglove. As soon as the pain is relieved by the remedies already enumerated, and more especially when the diet is complete and fluid, it is desirable to exercise the escape of the concretion into the duct before it would seem to be advantageous to prepare an open nile of the bowels for some days, not only for the purpose of carrying the concretion out of the body, but to abate in expediting the discharge of the bile tingling the serum of the blood, and the healthful renewal of the latter. The choice of the purgative for this purpose would seem to be not very material; caltor oil, moderate doses of calomel succeeded by neutral salts or rubarb, &c. repeated every third day, may answer the proposed end.

When there is complete evidence, from the colour of the stools, &c., that the obstruction is removed from the gall-duct, little farther aid from medicine, than the means just stated, would seem to be requisite. Perhaps, however, the restoration of the functions of the stomach and adjoining organs may be accelerated by the administration of some aromatic bitters, such as an infusion of camomilla or gentian; or of the absorbent or antacid medicines, when heart-burn or pain of stomach remains.

Such is the treatment to be adopted, whether the jaundice arise from spawn merely, or from gall-stone, or infusinated bile, stopping the duct. Except in the case of gall-stone, the disease will soon disappear. But in the latter instance, it often happens that the concretion, either from its magnitude or from its angular form, produces inflammation of the duct. It then becomes a more serious complaint, and requires the use of blood-letting, blisters, and purgatives, as in other visceral inflammations. The superintervention of inflammation is principally marked by the increase in the velocity and hardness of the pulse. The tendency to inflammation, indeed, in strong and plectic habits, from such an irritation in a membranous part as the passage of a biliary concretion exercises, is so great, that experienced physicians recommend the employment of blood-letting, by way of precaution, in persons of moderate vigour, even before the pulse is quickened, or febrile symptoms have superseded; and deem it absolutely requisite, when the pain is severe and the slightest degree of feverishness is present. (Cullen, loc. cit. § 182.) One full bleeding, produced from a large orifice in a vein, to the extent of 18 or 20 ounces, in a strong person, will be more efficacious than twice the quantity taken at repeated times.

It must here be observed, that various attempts have been made to discover medicines which might act upon the biliary concretions as solvents, while they remain in the gall-bladder or biliary ducts. Several substances have been found to dissolve the most common ones when directly applied out of the body, especially ether, oil of turpentine, spirit of wine, and the alkalies; and the combination of the two former, as well as solutions of essential oils in alcohol, have been administered internally both in France and this country, and their efficacy strongly attested. (See two papers on this subject, by M.M. Durande and Mare. in Les Nouveaux Memoires de l'Acad. de Dijon, tom. i. and ii. &c. White's Essay on Diseases of the Bile.) But it is to be recollected, that it is altogether impracticable to make a direct application of these substances to calculi in the biliary passages, and we have no facts to prove that they can be carried into the gall-bladder, through the medium of the circulating-blood, so little changed as to preserve any sensible degree of solvent power. Dr. Saunders, however, affirms that the alkalies have been found by experience, when taken for some continuance, to be successful against biliary concretions; and it has been generally stated, that flalled oxen get rid of their biliary calculi when turned out to graze in the spring, which, if it be true, implies the possibility of some change being effected upon calculi already formed. This statement induced some practitioners, who ascribed the effect to the new food which the cattle obtained, to give grafs, or the juice of it, to their human patients affected with jaundice. Van Swieten affirms, that cured a poor labourer by prescribing a decoction of grafs, sweetened with honey, for his common drink. (Comment ad Aplh. 950.) But these practitioners did not recollect that a free muscular exercise in the open air was an important point in the alteration of the circumstances of the cattle just mentioned; and whether we look to the sedentary habits of those who are more particularly disposed to jaundice, or to the beneficial effects of exercise, especially on horseback, which experience has ascertained, in preventing the flagration and vividity of the bile (see Saunders, p. 255; Powell, p. 161.), we shall not be disposed to fend our jaundiced brethren to graze for the recovery of their health.

Acids were long ago considered as beneficial in many cases of jaundice (Baglivi, Prax. Med. lib. i. cap. xii.); and the diluted nitric acid has recently been recommended in some diseases of the liver. Dr. Powell was hence induced to administer this acid to a patient who was subject to frequent attacks of jaundice from biliary concretions; and when the use of the acid for eight months he continued free from the disease. The writer of this article was induced to administer the nitric acid from the same considerations, and has witnessed the most decided efficacy of the remedy in several instances in which the disease speedily yielded to its influence again and again, after returning on desisting from its use. In one case, a young lady has experienced from it an invariable cure, and from the disposition to a recurrence of the jaundice has found it expedient to employ it almost continually. It may be taken in the proportion of a dram of the diluted nitric acid to a pint of distilled water, or of any vegetable infusion, daily.

In that state of the liver which produces jaundice towards the end of intermittent fevers, mercury is the best and only remedy; and calomel, in small doses, is the form under which, in this, and some other hepatic disaeases, it seems to act most powerfully. Wherece the febrilitis of the substance of the liver, or of the neighbouring organs, operates mechanically by its pressure upon the ducts, and occasioned jaundice, it is more likely to prove the resource of permanent mischief than any other cause; and our means of relieving it are less effectual. In the true tubercle of the liver, which begins with induration,
induration, and afterwards passes on to ulceration, the efficacy of any medicine is very doubtful; even mercurials, when given in large quantities, and under any form, have not seemed to produce any decided advantage. They are absolutely injurious, according to the observation of Dr. Saunders, when symptomatic fever takes place. The chalybeate waters are recommended by the late mentioned physician, as giving that tone and energy to the system so very defective in cases of jaundice.

When jaundice arises from a general congestion of the vessels of the liver, general blood-letting, or, if the circumstances of the constitution and strength of the patient forbid that, local bleeding by leeches, or cupping-glasses afterunction, or the application of blisters to the hypochondrium, will be useful, together with the exhibition of purgatives; and if it be admitted, that torpor of the intestinal canal, and a retention of bile or an accumulation of mucus in the duodenum can sufficiently obstruct the departure of the bile, and thus occasion jaundice, as it seems to do in young children, the employment of any active purgative will be adequate to its removal. Calomel and jalap are particularly well suited to this indication.

Horses are subject to jaundice as well as men. The farriers commonly call it the yellow, and divide it, as we do the jaundice, into two kinds, the yellow and the black. The yellow kind is known by the creature's white of his eyes turning to a yellowish colour, and his tongue and lips also partaking of the same tinge, but in a smaller degree. In the black kind all these parts are tinged with a darkish or blackish colour. The common cure among the farriers is by means of an ounce of mithridate dissolved in two quarts of strong-beer, and given to the horse warm; and repeating this dose once in twelve hours, as long as the distemper continues.

JAUNDECE-Bird, literat. in Ornithology, a name by which several of the old authors have called the gaula, a bird of the turtled kind, very beautifully coloured all over with a gold yellow, but with black wings. See ORIOLES GALLULI.

JAW, in Anatomy, the bone in which the teeth are lodged: there are two, an upper and a lower one. These are described in CRANIUM. The joint and muscles of the lower jaw are Considered under DEGLUTITION.

JAW, Diffusion of. See LUXATION.

JAW, Fractures of. See Fracture.

JAW, Loosened. See TRIMUS AND TITANUS.

JAWATA, in Geography, a town of Japan, in the island of Nipon; 90 miles W.N.W. of Mexico.

JAWBERRY, a town of Bengal; 21 miles N.W. of Calcutta.

JAWOR, a town of Lithuania, in the patrimine of Novogrodek; 48 miles S.S.W. of Novogrodek.

JAWOROW, a town of Poland, in New Galicia, celebrated for its warm baths; 25 miles W. of Lenberg.

JAXARTES. See Shimon.

JAY, GUY-MICHAEL, in Biography, a learned ad-

vocate of the parliament of Paris, who flourished in the 17th century, was at an early age profoundly skilled in the Oriental languages, and formed, at that period, the noble design of publishing a polyglott at his own expense. He carried the plan into execution, but it was with the expenditure of all his property. He might have reimbursed himself, and have also received an ample compensation for his long and almost unremitting labours, if he would have accepted the patronage of cardinal Richelieu, who was ambitious of a similar reputation to that obtained by Ximenes, for patronizing the Spanish Polyglott, but M. le Jay chose to refer to himself all the glory of the undertaking. On account of his poverty he embraced the ecclesiastical life, and obtained a small deanery, but his income was very inadequate to his wants, till cardinal Mazarin made him a magnificent present of nineteen thousand livres. The king likewise granted him letters of nobility, and a brevet of councillor of state as rewards of his learning, zeal, and disinterestedness.

He died in the year 1675. His Polyglott is in ten volumes. folio: it contains the Syrac and Arabic versions, with their Latin translations, and the Hebrew Samaritan text of the Pentateuch, with the Samaritan translation of the name in Samaritan characters. The high price at which this Polyglott was offered for sale in England, induced Walton to publish a similar work, which is more complete and commodious, though not so handsome, as M. le Jay's. Moreri.

JAY, in Geography, a township of America, in Kannebeck county, and state of Maine, thus named in honour of John Jay, governor of the state of New York. It lies on both sides of Great Meradegon river, and includes the great bend which, from an easterly and westerly course, suddenly turns southerly in this township, and passes into Livermore, containing 450 inhabitants. The Indian name of this place was "Rochomeoke."

JAY, in Ornithology, is the English name of the CORYUS GLANDARIUS; which lee.

JAYA, in Hindu Mythological Romance. Jaya and Vijaya were two of the daughters of Dakhia, son of Brahma. When Rama went forth to the wars of Lanka, the gods and demigods endowed and armed him with their potencies and weapons. These two filters of "Lighten well," as they are described in the Ramayana, brought forth a hundred weapons, and their house, and manual," wherewith to arm Rama and his companions in their arduous conflicts with Ravana, the tyrant of Lanka.

JAYADEVA, in Biography, a celebrated Hindoo poet, whose lyrics, entitled "Gita Govinda," introduced to the literature of Europe by the elegant pen of the lamented Sir William Jones, seem to give him a claim to an elevated rank in that species of composition. The "Gita Govinda" is a pastoral drama, exhibiting the loves of Krishna (under the name of Govind) and his mistress Radha; and although apparently a mere volupitous rhapsody of passion, and that not always devoid of groenefs, embellished by exquisite touches of poetry, it is contemplated in a very different light by the enthusiasts of the Gokaldah feit, or the exclusive adherents of Krishna. These persons may discover in the "Songs of Jayadeva," as the poem is called, a system of emblematical theology: the loves, apparently carnal, of Krishna and Radha, mean, they say, the reciprocal attraction between the divine goodnens and the human soul; and in this manner the voluptuoufnens of the poem is explained and lost. Others of a more sober cast passionately admire the profuse beauties of the Gita Govinda, without admitting it to be a composition exclusively spiritual. It is certain that a figurative mode of expressing the fervour of devotion obtained extensive prevalence in very early times. Among the Jews, Mah-
hometakers, and Hindoos; striking examples can be seen in this place. The doctrine of
Kathava, and not to mention the place of the doctrines pro-
mulgated in the same glowing style by the illustrious Greek
travellers, Pythagoras and Plato, who, it may be safely
affirmed, are among many of their tomes, as well as peculiarly
of expression, from the myths of India and Persia. See

MYSTICAL POETRY.

Jayadeva is believed to have lived anterior to the Christian
era, and to have been born at the town of Cendalli, in
Kalinga; but as there is a town of a similar name in Berdwan,
the natives of it claim the glory of citizenship with the
noted lyric poet of India, and celebrate in his honour
an annual jubilee, passing a whole night in representing
his drama, and singing his beautiful songs.

Jayadevi, the companion of Vishnu, is an equivocal
incarnation under the form of Jina or Jaina, as appears in
some Hindoo writings. She is represented preaching to the
females of Kari or Benares, the Jaina doctrine, that "all
true religion consists in killing no creature that has life;"
and a heresy, according to Brahmanical authors, which gained
so much ground, as to render an incarnation of Siva the avenger
of those who killed the gods. This incarnation, they say, accord-
ingly took place, in the person of a learned giant named
Sankara, which fee.

JAYES, in Geography, a town of Hindooftan, in Oude ;
30 miles N. of Mainpore.

Jaygong, a town of Bootan; 25 miles N. of Byehar.
Jayna, a canton, parish, and river on the S. side of
the island of St. Domingo; between this river and the
Nimag is enclosed an extensive and fertile plain, which was
formerly an abundant source of riches to the colonists. The
quantity of pure gold that was dug from its cavities, its
fugar, cocoa, indigo, and other plantations, paid duties to
a greater amount than those now paid by all the Spanish
provinces in the island. The inhabitants are wholly employed
in the breeding of cattle or the washing of gold sand.
Indigo grows well here. Towards the source of this river,
which at 250 miles from its mouth is not fordable, but crossed
in canoes and skins, were celebrated gold mines of St.
Christopher's near which Columbus erected the fort of that
name. On this river there are also rich silver mines. The
estabhishment in the plain of St. Rofe, and those on the
Jayna, are reckoned to contain 2000 persons.

Jaynagur, a town of Bengal, six miles N.E. of
Mahmedpore. N. lat. 23° 28'. E. long. 89° 46'.—Alfo,
a town of Bengal; 42 miles N. of Ramgur. N. lat. 24°
21'. E. long. 85° 53'.—Alfo, a town of Hindooftan, in
Bahar; 15 miles N.N.E. of Durbangh. N. lat. 26° 33'.
E. long. 86° 20'.

JAYPOUR, a town of Hindooftan, in the county of
Orissa; 192 miles W.S.W. of Cuttack. N. lat. 19° 5'.
E. long. 82° 48'.

Jayspiz, a town of Moravia, in the circol of Znivn;
10 miles N. of Znivn. N. lat. 48° 57'. E. long. 15° 53'.

Jazab, or Jazare, in Scripture Geography, a city be-
Low Jordan, given to Gal, and afterwards to the Levites.
(John, xxii. 36; xiii. 21.) It lay at the foot of the mountains
of Gilead, near the brook Jazer, which discharges itself
into the Jordan.

Jazirah, Desert of; a tract of Asiatic Turkey, extend-
ing along the Escuprates from Bals to Ambar. See GE-
ZIRA.

Jazyges, in Ancient Geography, a people of Scythia,
or Sarmatia. Of these there were the Jazyges Mesar, who oc-
cupied the northern coast of the Pallas Maris, and were destroyed in
the 15th century by the kings of Poland ; and also the Jazyges
Metanges, who inhabited the angular territory formed by the
Tisplus with the Danube. They lived in the vicinity of
Dacia, and are called by Pliny "Sarmates." The Jazyges
Bajus, or royal, were people of Sarmatia, joined by Strabo
to the Jazyges on the coast of the Euxine sea. These
advanced in process of time to the banks of the Danube, and
penetrated to the other side of the Sarmatian mountains.
They have been sometimes confounded with the Getae and
Dacians, on account of the resemblance that subsisted be-
rween them in their manners and mode of government.
Ptolemy speaks only of the Jazyges Metanges, who were
probably more considerable than any of the other Jazyges ;
and whose country was bounded on the N. by European
Sarmatia, S. E. by the Sarmatian mountains, as far as mount
Carpathus, and W. and S. by that part of Germany which
extends from the Sarmatian mountains to the Danube, near
Carpis, and thence by a part of this river to the Tisplus;
and E. by Dacia, from which it is separated by the Tis-
bicus. Towards the decline of the empire, this country
was occupied by the Vandals, and afterwards became a part
of the empire of the Goths. About the year 350 they
were expelled by the Huns. It has since formed part of
Hungary and of Galicia, and probably also of Bannat-Te-
meswar.

I'AGE, in Geography, a town of New Granada, in
the province of San Juan de los Llanos ; containing about
400 inhabitants, one half of them being Indians.

IBALL, a town of European Turkey, in Macedonia,
situated near Drino Nero; 65 miles W.N.W. of Akrida.

IBAR, or Bhara, a river of European Turkey, which
runs into the Morava; 20 miles N. Precop.—Alfo, a
town of Servia; 20 miles N. of Novi-Basar.

IBARRA, Joaquin, in Biography, born at Saragossa
in 1725, became printer to the king of Spain, and died in
1785. He carried the typographic art to a degree of
perfection which had been unknown in that country. He
produced very fine editions of the bible, the Mozarabic Missal,
Mariana's History of Spain, Don Quixote, and Gabriel's
Spanish Translation of Shalil.

IBARRA, in Geography, a town of South America, in
the province of Quito; 45 miles N.N.E. of Quito. N. lat.
25°; W. long. 77° 40'.

IBAROTI, a town of South America, in Paraguay;
130 miles E. of Asfumption.

IBAS, in Biography, bishop of Edessa, who flourished
in the fifth century. He was a Syrian by nation, and
appears to have been elected to the see of Edessa about
the year 456. While he was a presbyter of that church, he
wrote a letter concerning the council of Ephesus, and the
condemnation of Nellorius, in which he was thought to
favour the Nestorian doctrine. He was several times tried
upon this charge, and obtained verdicts of acquittal. He
was frequently harassed, and sent from one place of con-
finement to another, till, in the year 451, the council of
Chalcedon pronounced his sentiments orthodox, and decreed
that he should be restored to the dignity of which he had
been deprived. Moreri.

IBBERVILLE, in Geography, a river, or a kind of na-
tural canal of Weil Florida, which joins the Mississippii when
it overflows, and forms a communication for vessels drawing
three or four feet, from the Mississippii to the gulf of Mexico,
cut-yard, through the lakes Maurepas and Pontchartrain.
Its junction with the Mississippii is at the town of Manfack,
in N. lat. 30° 17'.

IBBETSON, Cape, a cape on the N.W. coast of Pitt's
Archipelago. N. lat. 54° 4'. E. long. 229° 31'.

IBBETSONIA,
IBBETSONIA, in Botany, is named by Dr. Sims in Curtis's Magazine, p. 1359, after an ingenious writer on the structure and physiology of plants, in Nicholson's Journal, Mrs. Agnes Jebbion. It is, however, the Cyclophia of Ventenat, a genus previously published by that author, and cited by Mr. Brown in the third volume of Mr. Atson's Horus Kewensis, not yet finished. — The plant in question is Sophora geniflora of Linnaeus and Thunberg, Podalyria geniflora of Willdenow, Sp. Pl. v. 2. 562, and Gompholobium Matudae of Andr. Repof. t. 427.

IBBOT, BENJAMIN, in Biography, an English divine, was born at Braewamall, in Norfolk, in 1685. After he had received the elements of a learned education he was entered of Clare-hall, Cambridge, where he took his degree of B. A. in 1669, and in the following year he removed to Corpus-Chrilli college, and was made a fellow of that house. He was, in 1707, taken into the family of archbishop Temmison as librarian, and soon after the prelate made him his chaplaine. After this he obtained considerable preferment in the church, and in 1716 he was appointed one of the chaplains in ordinary to king George I., and when his majesty visited the university of Cambridge, in the following year, his chaplain was created doctor of divinity by the royal mandamus. Shortly after he was appointed assistant preacher to the celebrated Dr. Samuel Clarke, and presented to the rectory of St. Paul's, Shadwell. In 1724 he was presented to a prebend at Westminster, and died in the following year. Two volumes of his sermons were published for the benefit of his widow by Dr. Clarke in the year 1726; and soon after his "Course of Sermons preached at the Lecture founded by the Honourable Robert Boyle." These are regarded as matterly replies to Mr. Collin's "Discourse on Free-Thinking."

IBET, in Geography, a town of Africa, and capital of a district, in Kordofan; 140 miles W. of Sennaar. N. lat. 14° 20'. E. long. 31°.

IBEK, in Biography, the name of Schebbeddin, sultan of India, usurped the throne on the death of his master, and added to his dominions many provinces of Hindoostan. An account of his conquests was written in a volume, entitled "Tage al Mather." D'Herbelot, Bibl. Orient.

IBERA, in Ancient Geography, a town of Spain, seated on the Iberus or Ebro, which is represented by Livy (l. xxiii. c. 25.) as a very rich city, when the Romans took it.

IBERIA, M. J., a name given by the generality of Greek writers to Spain, either from a colony of Iberians, a people bordering on mount Caucasus, planted there; or from the river Iberus, the Ebro of the moderns, one of the most famous rivers of this country. However, the ancients, who lived before Polybius, by Iberus understand only that part of Spain extending from the Pyrennees to Calpe, or the straits of Gibraltar, and terminated by the Mediterranean; the other part being unknown to, and consequently having no name among the Greeks and Romans. The true and proper Iberia is supposed to have been originally that part of Spain called Celtiberia (which see), from a body of Celts who settled in it, bounded by the Iberus, the Pyrenees, and the Mediterranean. See Hispanic.

IBERIA was also a country of Asia, between the Euxine and Caspian seas. According to Ptolomy, it was bounded on the N. by a part of Armenia, on the E. by Alaba, on the S. by the Greater Armenia, and on the W. by the Colchide. See Georgia.

Gen. Ch. Cal. Perianth inferior, of four obovate, concave, small, spreading, equal, deciduous leaves. Cor. Petals four, unequal, obovate, oblong, spreading, with long upright claws; the two external ones much the largest, of equal size; the two inner very small and reflexed. Stam. Filaments six, awl-shaped, erect, the two lateral being shorter; anthers roundish. Fil. German superior, roundish, compressed; style simple, short; stigma blunt. Peric. Pouch erect, nearly orbicular, compressed, notched, surrounded with an acute border, two-celled; partition lanceolate; valves boat-like, compressed, keeled. Seeds few, nearly ovate.

Eft. Ch. Corolla irregular; its two outermost petals largest. Pouch emarginate, with several seeds.

This genus is singular in its natural order for the unequal petals, constituting an irregular flower, and affording a most decisive effeential character. Reichard observes that in I. roundifolia the petals are nearly equal; but we find them by no means so as to invalidate this character.

The species are eighteen in Willdenow, mostly herbaeous, half of them annual or biennial, some few of the reit rather shrubby. We have two in England, I. amara, Engl. Bot. t. 52, found in chalky fields but rare, distinguished by its brilliant white flowers, which sometimes procure it a place in the flower-garden; and I. medicina, Engl. Bot. t. 527. Curt. Lond. f. 6. t. 42, found here and there on gravelly ground in the spring. Both these are annual.

I. sempervirens and I. umbellata are very frequently cultivated for ornament. The former is perennial and rather shrubby, conspicuous for a profusion of white blossoms, and well calculated to adorn rock-work; the latter, figured in Curt. Mag. t. 106, is a hardy annual, with purple flowers of various dyes.

I. linifolia is very nearly allied to the latter, of which indeed Linnaeus at one time reckoned it a variety.

IBERUS, in Ancient Geography. See Ebro.

IBET, in Geography, a town of Turkish Armenia; 33 miles S.S.W. of Akalziké.

IBEX, in Zoology, the name of an animal of the goat kind. (See Capra laxis, &c.) This name is also given to some species of Antilopes; which see.

IBIBOCA, the name of a species of serpent called by the Portuguese cobra de coroa. It is about two feet in length, and of the thickest of a man's thumb; and tapers off at the tail to a thimble, till at last it ends in a sharp point. Its belly is all over white, and very bright and glossy; and its head is covered with white scales of a cubic figure, and with some black ones towards the edges. Its body is variegated with black, white, and red. It is a very flow mover; but is of a very terrible and poifonous kind. Ray.

TBICARAM, a name given by Piso to a species of Cacilla; which see.

IBIARA, the name of an American species of serpent, called also boddy, and by the Portuguese cegã, cobra cegã, and cobra de las cabezas. It is of the amphibian kind and is generally said to have two heads, one at each end; but this is wholly erroneous. The head and tail are of the same shape, and of equal thickness, and the creature will strike equally with either; and, as it is said, its poison is equally contained at both. It is a snake of the smaller kind, being about a foot long, and as thick as one's finger. It is white.
I B R

white in colour, and as shining and glossy as glass; and is very elegantly marked with rings and streaks of a brown or copper colour. Its eyes are small, and scarcely conspicuous, looking only like dots made by the point of a needle; it lives under ground, and feeds on ants and other small insects. It is often thrown up in digging; and the Portuguese say, it is a creature whose poison is beyond the reach of all the known remedies. Ray.

IBJAAU, in Ornithology. See CEPHALOCEPS grandis.

IBIPITANGA, in Botany. See Plinia.

IBIRA, a name given by some authors to the tree which produces the cudbeor, or cushions of the shops.

IBIRACOA, in Zoology, the name of a species of serpents found in the West Indies; whose bite is always attended with very terrible effects. It is of a variegated colour, mottled with black, white, and red.

IBIS, in Ornithology, the name of an Egyptian bird, said by some to be a species of Aegypt or Heron; by others of Tanatolus; and by others of Numenius, or Curlew. See each of these articles, and also Hassaleag. It is said to be peculiar to Egypt, and is there very serviceable in destroying the serpents, locusts, and other devouring insects; and hence it was, that, in early ages, they had divine honours paid them. Such is the account given by Herodotus, Diodorus Siculus, and Cicero.

It is remarkable with regard to this bird, that although it lives principally about the Nile, yet it never enters the water, nor can it swim. The use of glyders is said to have been learned from the ibis, and not from the flork. It generally builds its nests upon the palm-trees, to avoid the cats. Aldrovandus relates, that the flesh of the ibis is red, like a falcon's, that it is sweet, that its skin is very hard, and smells like wild fowl. This subject has been treated at large by M. Savi-nv, in his "Hist. Nat. et Myth. de l'Ibîs," Paris 1805, Svo. He first traces the description from the ancients, who mention the white ibis and the black, though the latter be not strictly black, but of a deep brown colour, with beautiful metallic reflections. But if the bitumen employed in embalming was too much heated, the feathers of the white ibis became black. That the ibis devoured serpents is a mere imagination of the ancients. Like the other birds of its kind, even the red curlew of Cayenne, and the white of Carolina, it could only have devoured worms, little fish, and aquatic insects. At present the white ibis is not regarded as resident in Egypt. According to the report of the inhabitants, these birds arrive when the Nile begins to increase, probably the real cause of the ancient veneration; their number augments as the river rises, and diminishes with its decrease, after which they return to Abyssinia. They would appear to reside in Egypt about seven months, at least in the Delta. The black, or rather brown ibis, arrives and returns later than the white. According to this account the ibis generally arrives in Egypt in June, and retires in October, though some may linger till December.

IBITTIN, in Zoology, the name of a very large and dangerous serpent in the Philippine islands. This animal twills its tail round the trunk of a tree, and strikes its prey, as men, deer, &c. which it entirely devours, and then squeezes itself against the tree, in order to digest what it has eaten.

IBITUPOCA, in Geography, a town of Brazil, in the province of Minas Geraes; 32 miles S. of Villa Rica.

IBIPOETUBA, a small island in the Atlantic, near the coast of Brazil. S. lat. 25° 39'.

IBRAHAM, in Biography, the sultan of the Turks, succeeded his brother Amurath or Morad IV. in 1640, being then in his twenty-third year. He had been long a prisoner at the instance of Morad, who would have put him to death had he not been prevented by his mother; and such was the state of his mind, that he refused admission to the great officers of the government when they came to announce his brother's death, and his own accession to the throne, nor could he be prevailed on to open the doors of his dungeon till the dead body of Morad was laid in his view. Ibrahim was ill fitted for the cares of a crown, and refigned the duties of his station to his ministers, contenting himself with trifling amusements and gross voluptuosities. One of the first events of his reign was the capture of Azof, the principal post of the Collock pirates who infested the Black sea; by which measure their depredations were repressed, and the navigation rendered clear to Constantinople. An attempt was made upon the island of Candia, but it was not successful. The licentious deeds of Ibrahim were the cause of his death: he had violated the chastity of the beautiful daughter of the Mufti, who, resolved upon revenge, took such means as to effect the end. He ordered the sultan to appear before him, which he refused; he then declared him an infidel, and incapable of exercising the authority of government. The jahizaries took the part of the head of the church, and he was almost immediately strangled. This was in the year 1649: he left several sons, of whom three successively filled the throne. Mod. Univer. Hist.

IBRAHIM AL-SHRAZI, a celebrated Mussulman doctor, a native of Shiraz, the capital of Fars, or Persia properly so called. It is not known at what period he flourished, but he figures a very high rank among the exponents of the law, and was author of many works in Arabic, very highly esteemed. The principal of these are "An Exhortation to the Study of Jurisprudence," "The Exemplar," an illustration of the principal articles, or, as the Mahometans call them, the foundations of the law. He is supposed to have been the author of a work on the art of scholastic disputations, with the Arabic title, signifying "The Search after Truth."

IBRAHIM AL-MEROUZI, a celebrated Mussulman doctor, who derived his surname from the city of Merou, in the province of Korasa, where he was born. He wrote many pieces in the Arabic language, which are greatly valued; and among others a commentary on the "Mozi," consisting of an abridgment of Mussulman law. At Bagdat, where he resided, he was consulted as an oracle in all matters relating to jurisprudence. In advanced life he removed from Bagdat to Cairo in Egypt, where he died in the year 340.

IBRAHIM BEN IBRAHIM MISHIBAN, one of the celebrated doctors of the sect of Schafis, was author of many works of high reputation, of which the chief is a defence of the Mussulman law against the objections of those unbelievers and Atheists described under the Arabic title, signifying "Men without Religion." He died in the year 1418 of the hegira. A more full account of the person just mentioned may be found in Herbelot's Bibl. Orient.

IBRAHIM EFFENDI, a native of Poland, who was raised by his courage and talents to the principal dignities in the Ottoman empire. He established the first printing-press in Turkey. The earliest work which he produced was on the military; he afterwards published the "Account of an Expedition against the Afghans;" "A Turkish Grammar;," and "A History of Turkey."

IBRAHIM, in Geography, a mountain of Arabia, in Yemen; 40 miles S. of Chamas.

IBRAHIM BATA, a river of Syria, anciently Adonis, (which see).
ICA

ICA, or Yaqu, or Falvanda, a town of Peru, in the audience of Lima, and one of three towns, which give name to a province called "ICa Pisco and Nafca." It is situated in a valley, and its principal commerce consists in grain, wine, brandy, &c.; it contains about 60,000 souls; 140 miles E.S.E. of Lima. S. lat. 13° 50'. W. long. 75° 28'. 

Vor. XVIII.

ICG

ICG, Pisco and Nafca, jurisdiction of, a province of Peru, in the audience of Lima, comprehending about 140 miles along the coast of the Pacific ocean, intersected with sandy defiles. The oil and wine yielded by this province are excellent, and supply the other provinces; and where the land is capable of being watered, it produces corn, maize, and a variety of excellent fruits. The inhabitants near the coast are employed in catching fish, which they cure and fend in great quantities into the inland country.

ICAO, in Botany. See Chrysoralanus.

ICARIDE, the name of an ancient feast, celebrated every month by the Epicurean philosophers, in memory of their master Epicurus.

The day on which it was held was the twentieth day of the moon, or month, which was that whereon Epicurus was born, and hence came the name icaries, from icores, of inces, twenty.

They adorned their chambers on this day, and bore his image in state about their houses, making sacrifices, &c.

ICARIA, in Ancient Geography, an island of the Ægean sea, situated W. of the isle of Samos, E. of that of Delos, and S.S.E. of that of Chios.

ICARIAN SEA, that part of the sea of the Archipelago into which Icarus fell. Thus Diodorus and Ovid deduce its name. "Icarus Icaria nominis ficti aquas." But the learned Bochart says, that this part of the Ægean sea was so called upon account of the isle Icaria, or Icaura, which, in the Phoenician language, imports 'fickle.'

ICARIA, an island of the Persian gulf, over-against the mouth of the Euphrates. Here, according to Strabo, were a temple and oracle of Apollo. Arrian calls it Icaros, Pliny, Ichara, and Toloemny, who places it on the coast of Arabia Felix, calls it Ichara and Icaros.

ICARUS, a river of Achaia, in Scythia, which flowed into the Ouxas, according to Pliny.

ICARES, in Fabulous History, the son of Dedalus, who was shut up by the king of Crete, with his father, who had favoured the amours of the queen in the labyrinth. As Dedalus knew all its mazes, he found no great difficulty in extricating himself; and having gotten a ship which Paphlagon had provided for him, he fixed sails to it, the use of which was not then known in Greece, and thus was able to desert Minos' califry which pursued him with oars. His son Icarus, having arrived in an island very remote from the continent, and endeavoring to land too precipitately, fell into the sea and was drowned; or, not having skill enough to manage his bargain, as we learn from Paupanias (in Beol.), perished near the island of Samos. The poets related this escape under the ingenious fiction of wings, the invention and use of which are ascribed to Dedalus; thus Horace, (Od. I. I.) speaks of them:

"Experius vacum Dedalus aeris
Pennis non homini datus,"

The young and adventurous Icarus, it is said, disregarded the wise counsel of his father, who recommended him not to soar too high, lest the heat of the sun should melt the wax with which his wings were fastened, while he himself flew near the surface of the water, and even took care, as Diodorus Siculus, remarks, to moisten his wings from time to time, lest they should be over-heated; and fell into the sea.

ICCIUS PORTUS, or ITUS PORTUS, the harbour of Gaul, whence Caesar embarked his troops for the invasion of England. Some have referred this harbour to Bologna, others to Wifden, and others to Calais.
ICE, a brittle transparent body, formed of some fluid, frozen or fixed by cold.

The specific gravity of ice to water is as eight to nine; or the specific gravity of water being 1, that of ice is .93; hence, being lighter than water, it floats upon it. The specific gravity of ice was tried by Dr. Irving, in Phibbs's voyage to the north pole; who found, that when a piece of the moist dense ice which he could meet with was immersed in snow-water, the thermometer 34°, fourteen fifteen parts sunk under the surface of the water: in brandy just proof, it barely floated; in rectified spirits of wine, it fell to the bottom at once and dissolved immediately. This rarefaction of ice has been supposed to owe to the air-bubbles produced in ice while freezing; these, being considerably large in proportion to the water frozen, render the ice to much specifically lighter. Accordingly, it is said, that a considerable quantity of air is lodged in the interstices of water, though it has not there any elastic property, on account of the diminution of its particles; but these particles coming closer together, and uniting as the water freezes, light, expansive, and elastic air-bubbles are thus generated, and increase in bulk, as the cold grows stronger; whence of course the ice grows lighter, and these air-bubbles acquiring an elastic force burst to pieces any vessel in which the water is closely contained. But snow-water, or any water long boiled over the fire, affords an ice more solid than ordinary, and with fewer bubbles. Pure water, long kept in vacuum, and frozen afterwards, there, freezes much sooner, on being exposed to the same degree of cold, than water unpurged of its air and set in the open atmosphere. And the ice made of water thus divested of its air will expand in freezing; though it is much harder, more solid and transparent, and more ponderous than common ice.

But M. de la Mairan, in a dissertation on ice, more justly attributes the increase of the bulk of the water under this form, principally to a different arrangement of its parts: the icy skin on water, being composed of filaments which are found to be joined constantly and regularly at an angle of 60°, and which, by this disposition, occupy a greater volume than if they were parallel. He found the augmentation of the volume of water by freezing, and in different trials a 14th, an 18th, and a 19th; but when the water was previously purged of air, only a 22d part. Besides, ice, after its formation, continues to expand by cold; a piece of ice, which was at first only a fourth part specifically lighter than water, on being exposed some days to the frost, became a 12th part lighter; and thus he accounts for the bulring of ice in ponds. See Congelation, Freezing, and Freezing Mixture.

To make the most perfect ice, we should take the purest water, and perfectly purify its air by the air-pump; then freeze it in the severest frost, by means of Mr. Fahrenheit's contrivance. Thus we obtain an ice of the greatest hardness, density, purity, transparency, and gravity.

It appears by an experiment of Dr. Hooke, in 1663, that ice refracts the light less than water; whence he infers, that the lightness of ice, which causes it to swim in water, is not produced merely by the small bubbles which are visible in it, but that it arises from the uniform constitution or general texture of the whole mass. This fact was afterwards confirmed by M. de la Hire. Hooke's Exper. by Derham, p. 26. Acad. Par. 1663. Mem. p. 25.

Dr. Wollaston has fully confirmed the observation of Dr. Hooke by means of an accurate instrument which he has contrived for determining the refraction of different substances; so that ice must be considered as the least refractive of any known substances that are not aeriform. The refractive power of ice is stated by Dr. Wollaston, and by Dr. Young, by calculation, from halos, at 1.34. (See Refraction.) The capacity for heat of water to ice is as 1.000 to .500; and the heat, in a given measure, is as 1.000 to .840. Ice is known to evaporate as well as water, and some say in an equal, others, in a greater degree. See Evaporation.

In the mountains of Switzerland there are immense masses of ice, which, by the tradition and histories of the country, must have lain there many centuries. At certain times there happen cracks in these, and by these cracks the vast thickness of the masses may in some measure be grieved at; some of them being three or four hundred ells deep, and yet none of them yet ever having gone through the whole thickinesse. The vast bodies of ice met with in the northern seas, near Hudson's bay, are surprising; some of them being immered a hundred fathoms or more under the surface of the ocean, and a fifth or sixth part above, and three or four miles in circumference. See Phil. Trans. N. 465. sect. 2.

These floating mountains of ice owe their vast bulk and durable nature to a cause not considered by many; that is, to their not being common ice, but the ice of sea-water; many experiments proving, that in acid and spirituous liquors, when the frost has power over them, the watery parts only are affected, and the ice is salted, while the liquor remains concentrated, and much stronger than before at the bottom or in the centre. It was generally supposed that the saline liquors, and consequently sea-water, were affected by freezing in the same manner; that is, its watery part alone was frozen, and the salt separated from the part fo congealed; but Dr. Lifter alleges, that the ice formed of sea-water is really salt, and does contain sea-salt; and finally that it is, by means of this salt contained in it, rendered more durable than common ice. If a phial of salt-water be exposed to the air in frosty weather till flakes of ice are found in it, and then brought into a warm room, these flakes will remain even in that place a long time undissolved; and if they are taken out and exposed at a small distance to the fire, they will not run into water as common ice would, but they will by degrees evaporate, and there will be left only a little white salt.

Since sea-water, when frozen, thus forms a very durable ice, it appears easy to conceive, that the immense masses of such ice found in the northern seas should continue undissolved through the whole year, and at the return of the freezing season remaining of the same bigness as at first; they must of consequnce then become much bigger by the freezing of more ice about them; and thus continuing to lose very little, and that only by accidents, and annually to increase a great deal, it is not wonderful that they become so large. Phil. Trans. N. 167. 836. See Sea-Water.

But there have been different opinions with regard to the origin of those vast piles of ice, resembling whole islands, in the northern regions. Some ascribe to snow, which falling in great abundance in those cold climates, and melting in the sea, accumulates gradually, till those huge heaps are at length formed; but the more common opinion is, that this ice is formed from the fresh waters which flow from the neighbouring lands. It is certain that great quantities of floating ice are discharged by the river Obly, and kept in a state of constant agitation by it. Bartoli has written an Italian treatise expressly on ice and coagulation. And the Acta Eruditorum furnish us with an account of a French author on the same subject. See Coagulation, Cold, and Crystallization.

The formation or coagulation of ice-islands has not yet been
been thoroughly investigated. Captain Cook (Second Voyage, vol. ii. p. 240) objects to the opinion of those who ascribe to the freezing of the water at the mouths of large rivers, or great cataracts, where they accumulate till they are broken off by their own weight. He says that no ice was found incorporated with their earth, or any of its produce, which must have been the case, if it had been congelated in land-waters. He doubts whether there be any rivers in the countries to which he refers: "it is certain," he says, "that we saw not a river or stream of water on all the coast of Georgia, nor any on the southern lands. Nor did we ever see a stream of water run from any of the ice-lands. How are we then to suppose that there are large rivers? The valleys are covered, many fathoms deep, with everlasting snow; and, at the sea, they terminate in icy cliffs of vast height. It is here where the ice-lands are formed; not from streams of water, but from congelated snow and drifts, which is, almost continually, falling or drifting down from the mountains, especially in the winter, when the frost must be intense. During that season, the ice-cliffs must of necessity form as to fill up all the basins, be they ever so large. This is a fact which cannot be doubted, as we have seen it so in summer. These cliffs accumulate by continual falls of snow, and what drifts from the mountains, till they are no longer able to support their own weight; and then large pieces break off, which we call "ice-lands." Such as have a flat even surface must be of the ice formed in the bays and before the flat valleys: the others, which have a tapering unequal surface, must be formed on, or under the sole of a coal composed of pointed rocks or precipices, or some such uneven surface. For we cannot suppose that snow alone, as it falls, can form, on a plain surface, such as the sea, such a variety of high peaks and hills, as we see so many of the ice isles. It is certainly more reasonable that they are formed on a coast whose surface is something similar to their. I have observed that all the ice-lands of any extent, and before they begin to break to pieces, are terminated by perpendicular cliffs of clear ice or frozen snow, always on one or more sides, but most generally all round. Many, and those of the largest size, which had a hilly and spiral surface, showed a perpendicular cliff or slide from the summit of the highest peak down to its base. This to me was a convincing proof that the, as well as the flat isles, must have broken off from the face similar to themselves; that is, from some large tract of ice." "These ice cliffs," Captain Cook apprehends, "extend a good way into the sea, in some places, especially in such as are sheltered from the violence of the winds. It may even be doubted if ever the wind is violent in the very high latitudes. And that the sea will freeze over, or the snow that falls upon it, which amounts to the same thing, we have instances in the northern hemisphere. The Baltic, the gulf of St. Lawrence, the straits of Belle-Ile, and many other equally large bays, are frequently frozen over in winter. Nor is this at all extraordinary; for we have found the degree of cold at the surface of the sea, even in summer, to be two degrees below the freezing point; consequently, nothing kept it from freezing but the height it contains, and the agitation of its surface. Whenever this last cessa in winter, when the frost is set in, and there comes a fall of snow, it will freeze on the surface as it falls, and in a few days, or perhaps in one night, form such a sheet of ice as will not be easily broken up. Thus a foundation will be laid for it to accumulate to any thickness by falls of snow, without it being at all necessary for the sea-water to freeze. It may be, by this means, these vast flats of low ice are, in the spring of the year, formed, and which, after they break up, are carried by the currents to the north." The northern ice extends about 9° from the pole; the southern 18° or 20°; in some parts even 30°; and floating ice has occasionally been found in both hemispheres as far as 45° from the poles, and sometimes, as it has been found, even in latitude 41° and 42°. Between 54° and 60° of the southern latitude, the snow lies on the ground, at the sea side, throughout the summer. The line of perpetual congelation is three miles above the surface of the earth, where the mean heat is 8°: at Teneriffe, in latitude 28°, two miles; in the latitude of London, a little more than a mile; and in latitude 80° north, only 1200 feet. At the pole, according to the analogy deduced by Mr. Kirwan, from a comparison of various observations, the mean temperature should be 31°. In London, the mean temperature is 50° at Rome and at Montpellier, a little more than 60°; in the island of Madeira, 70°; and in Jamaica, 80°. See CONGELATION, COOLING, and TEMPERATURE.

Sir Robert Barker has particularly described the process of making ice in the East Indies, where, during his time, he has never seen any natural ice. For this purpose they dig on a large open plain, a stone or four pits, about thirty feet square, and two deep each; the bottoms of which they cover about eight inches or a foot thick with sugar-cane, or the stems of the large Indian corn, dried. On this bed are placed in rows a number of small shallow unglazed earthen pans, formed of a very porous earth, a quarter of an inch thick, and about an inch and a quarter deep; which, at the duff of the evening, they fill with hot water that had been boiled. In the morning, before sunrise, the ice-makers attend at the pits, and collect what was frozen in baskets, which they convey to the place of preservation. This is generally prepared on some high dry situation, by sinking a pit fourteen or fifteen feet deep, lining it first with straw, and then with a coarse kind ofblanketing. The ice is depo-
ICE

ner in which large fragments of rocks have been transported, to places far distant from their native situations, on maffles of ice, floating on the ocean, before it had been reduced to its present limits; according to the theory of Mr. Jameson, Geognosy, vol. iii. p. 33. Mr. Playfair supposes, in his illustration of the Huttonian theory, § 348, that glaciers or inclined planes of ice, existing on the surface of the earth, previous to the excavation of valleys, were the means of transporting many of such blocks, those of granite in particular; an opinion ably combated by M. De Luc, in his Geology, § 234: but whose explanation of this important and very common phenomenon, viz. that they were projected into the air, from cliffs, or fissures in the earth, extending down to certain great subterranean caverns, by the force of vast currents of air and water issuing therefrom, seems (says Mr. Farey) less probable, than that recently offered by himself, viz. that the extraneous blocks of stone, and all other alluvial matters found on mountains and hills, were transported during the disturbed and reverted action of gravity, occasioned by the perigee visits of a former satellite. See Philosophical Magazine, vol. xxxvi. p. 6.

Ice-cream. Method of making. Take a sufficient quantity of cream, and, when it is to be mixed with raspberry, currant, or pine, a quarter part as much of the juice or jam as of the cream; over beating and straining the mixture through a cloth, put it with a little juice of lemon into the mould, which is a pewter vessel, and varying in size and shape at pleasure; cover the mould, and place it in a pit about two-thirds full of ice, into which two handfuls of salt have been thrown; turn the mould by the hand-hold with a quick motion to and fro, in the manner used for milling chocolate, for eight or ten minutes; then let it reit as long and turn it again for the same time; and having left it to stand half an hour, it is fit to be turned out of the mould, and to be sent to table.

Lemon juice and sugar, and the juices of various kinds of fruits, are frozen without cream, and when cream is used, it should be well mixed.

Ice-houses, in Gardening, a sort of building sunk in the ground for the purpose of preserving ice for use during the summer season, when the weather becomes hot.

Situation. The proper situation for an ice-house, is that of a dry spot of ground; as wherever there is moisture the ice will be liable to dissolve; of course in all strong foils, which retain water, too much care cannot be taken to make drains all round the houses to carry off moisture; as when this is lodged near them, it will occasion a damp, which is always prejudicial to the keeping of ice in them.

The aspect of ice-houses should be towards the eait or south-east, for the advantage of the morning sun to expel the damp air, as that is more pernicious than warmth; for which reason, trees in the vicinity of an ice-house tend to its disadvantage.

The bell foil for an ice-house to be made in is chalk, as it conveys away the walle water without any artificial drain; next to that, loose sandy, or gravelly soil.

The places should likewise be elevated, that there may be decent enough to convey off any wet that may happen near them, or from the ice melting; and also as much exposed to the sun and air as possible; not under the drip, or in the shade of trees, as is too often the practice, under the supposition, that if exposed to the sun, the ice will melt away in summer, which never can be the case where there is sufficient taken to exclude the external air, as the heat of the sun can never penetrate through the double arches of the buildings, so as to add any warmth to the internal air; while, when entirely open to the sun and wind, all damp and vapours are readily removed.

Stage. The external form of the building may be according to the fancy of the owner; but for the well, into which the ice is put, a circular form is the most convenient; the depth and diameter of it being proportioned to the quantity of ice wanted; but it is always best to have sufficient room, as when the house is well built it will keep the ice two or three years; and there will be this advantage in having it large enough to contain ice for two years' consumption, that if a mild winter should happen, when there is no ice to be had, there will be a stock to supply the want in the house already.

Where the quantity wanted is not great, a well of fix feet diameter, and eight feet deep, will be large enough, but for a large consumption, it should not be less than nine or ten feet diameter, and as many deep; where the situation is either of a dry chalky, gravelly, or sandy kind, the pit may be made entirely below the surface of the ground; but in strong loamy, clayey, or moil ground, it will be better to raise it to high above the surface, as that there may be no danger from the wetness of the soil about it.

At the bottom of the well there should be a space about two feet deep left, for receiving any moisur which may drain from the ice, and a small underground drain should be laid from this, to carry off the wet; over this space should be placed a strong grate of wood, to let the moisur fall down which may at time happen, from the melting of the ice. The sides of the well must be walled up with brick or stone at least two feet thick; but if it be thicker it will be better, as the thicker the walls are made, the less danger there is of the well being affected by external caufes. When the wall of the well is brought within three feet of the surface, there must be another outer arch or wall begun, which must be carried up to the height of the top of the intended arch of the well; and if there be a second arch turned over from this, it will add to the goodness of the house; but this must depend on the person who builds going to the expense. When not, the plate into which the roof is to be framed must be laid on this outer wall, which should be carried high enough above the inner arch to admit of a door way in, to get out the ice. Where the building is to be covered with slate or tiles, there should be a thickness of reeds, straw, or other similar materials laid under, to guard against the effects of the sun and external air; where they are laid two feet thick, and platterd over with lime and hair, there will be no danger of the heat penetrating in such a way as to prove injurious.

The external wall of the house need not be built circular, but of any other form, as square, hexagonal, or octangular; and where it flands much in light may be fo contrived as to make it a pleasing object to the light.

But ice-houses may be built in such a manner as to have alcove seats in the front, having passages to get out, and put in the ice behind them; or the entrance may be behind to the north; small passages being left next the seats, through which to enter to take out the ice, a large door being contrived with a porch wide enough for a small cart to take in, to shoot down the ice upon the floor near the mouth of the well, where it may be well broken before it is put down. The aperture of this mouth of the well need not be more than two feet and a half in diameter, which will be large enough to put down the ice, a stone being left to stop it with, which must be closed up as securely as possible after the ice is put in, and all the vacant space above and between this and the outer door be filled close with barley straw, or other similar materials to exclude the external air from entering.
The door to enter by for taking out the ice should be no larger than is absolutely necessary for the coming at the ice, and must be strong and close to exclude the air, and at five or six feet distance from this another door should be contrived which should be closely shut before the inner door is opened, whenever the ice is taken out of the house.

When the house is thus finished, it should have time to dry before the ice is put into it; as when the walls are green the damp of them frequently diffuses the ice. And at the bottom of the well, upon the wooden grate, some small stakes should be laid; and if upon these a layer of reeds be placed smooth for the ice to roll upon, it will be better than straw, which is commonly used.

Proper sort of Ice.—In the choice of the ice, the thinner it is the better it may be broken to powder; as the smaller it is broken the better it will unite when put into the well. In putting it in, it should be rammed close, and a space left between it and the wall of the well, by straw being placed for the purpose, so as to give passage to any moisture that may be collected by the dissolving of the ice on the top or otherwise.

In putting the ice into the house, some mix a little nitre with it, to make it congeal more fully; but this is not necessary.

As the ice becomes solid in the well, an iron crow is necessary to take it up with.

The ice-house is, as has been seen, capable of being made an ornamental building; but this is seldom done; it being generally placed in a secluded spot, on the side of a hill or sloping ground, the base of which is lower than the bottom of the well, the outside being well banked up with earth, to keep out all external air and heat, and nearly covered with turf or thatch.

To construct an ice-house, first choose a proper place at a convenient distance from the dwelling-house or houses it is to serve: dig a cavity (if for one family, of the dimensions specified in the design) of the figure of an inverted cone, sinking the bottom, concave, to form a refouvoir for the water within till it can drain off; if the soil requires it, cut a drain to a considerable distance, or so far as will come out of the side of the hill, or into a well, to make it communicative with the springs, and in that drain form a flink or air-trap, marked / (Plate XX. Mefemby, fig. 5.) by sinking the drain so much lower in that place as it is high, and bring a partition from the top an inch or more into the water, which will constantly be in the trap, and will keep the well air-tight. Work up a sufficient number of brick piers to receive a cart-wheel, to be laid with its convex side upwards to receive the ice; lay hurdles and straw upon the wheel, which will let the melted ice drain through, and serve as a floor.

The fides and dome of the cone are to be nine inches thick, the fides to be done in fleened brickwork, i.e. without mortar, and wrought at right angles to the face of the work; the filling-in behind should be with gravel, loosestones, or brick-bats, that the water which drains through the fides may the more easily escape into the well.

The doors of the ice-house should be made as close as possible, and bundles of straw placed always before the inner door to keep out the air.

Definition of the parts referred to by the letters:

a The line first dug out.

b The brick circumference of the cell.
c The diminution of the cell downwards.
d The lesser diameter of the cell.
e The cart wheel, or joints and hurdles.
f The piers to receive the wheel or floor.
g The principal receptacle for straw.

The ice, when to be put in, should be collected during the frost, broken into small pieces, and rammed down hard in the firata of not more than a foot, in order to make it one complete body; the care in putting it in, and well ramming it, tends much to its preservation.

In a season when ice is not to be had in sufficient quantities, snow may be substituted.

Ice may be preferred in a dry place under ground, by covering it well with chaff, straw, or reeds. Phil. Trans. N. 84. p. 140. See Snow.

Great use is made of chaff in some places of Italy to preserve ice: the ice-house for this purpose need only be a deep hole dug in the ground on the side of a hill, from the bottom of which they can easily carry out a drain, to let out the water which is separated at any time from the ice, that it may not melt and spoil the cell. If the ground is tolerably dry, they do not line the sides with anything, but leave them naked, and only make a covering of thatch over the top of the hole; this pit they fill either with pure snow, or else with ice taken from the purest and clearest water; because they do not use it as we do in England, to fet the bottles in, but really mix it with the wine. They first cover the bottom of the hole with chaff, and then lay in the ice, not letting it any where touch the sides, but ramming in a large bed of chaff all the way between: they thus carry on the filling to the top, and then cover the surface with chaff, and in this manner it will keep as long as they please.

When they take any of it out for use, they wrap the lump up in chaff, and it may then be carried to any distant place, without waste or running. Phil. Trans. N. 8. See Ice.

Ice, Palace of, a palace built of ice by the empress Anne of Russia, on the bank of the Neva in 1740, 52 feet long, which, when illuminated, had a surprising effect.

Ice-plant, in Botany. See Mesembyanthemum.

ICELAND, in Geography, the largest island in Europe next to Great Britain, is surrounded by that part of the northern sea which geographers have called the Deucalidian ocean. Its length, from the most western cape to the most easterly, is about 260 British miles, and its breadth from north to south about 150 miles. Mallet indeed reckons its length from east to west at about 112 Danish miles (12 to a degree), and its mean breadth 50 of those miles. The number of its inhabitants is estimated at about 50,000, or one to the square mile. Nature herself hath marked out the division of this island. Two long chains of mountains run from the middle of the eastern and western coasts, rising by degrees till they meet in the centre of the island, from whence two other chains of smaller hills gradually descend till they reach
